*Consciousness is eternal, life is immortal.
Incarnate existence is Paradise on the Cosmic equator
in space-time – the living consummation of all worlds.
But mortally coiled! – As transient as the winds of fate!
This coil is as tough a bind as life and death can be,
but becomes the redemption of all that has passed before
and awakens nascent futures we can only but envisage.*

¹ This document is an active real-time research journey of discovery, that is a “trip” in itself for the beholder. It is an informational spore, finer than a mustard seed, to reflower the tree of living conscious diversity, through free circulation in intact form, to illuminate through the creative commons.

² *perennial* lasting or existing for a long or apparently infinite time; enduring or continually recurring. From Latin *perennis* ‘lasting the year through’ + -ial. Oxford languages. The term is used to indicate lasting throughout the lifetime of conscious existence in the universe.

The Core Nexus of Symbiotic Existential Cosmology

For Elinor, Albert, Isaac and Everyone

The Nature of this Communication

This work, presents an **augmentation of physical cosmology** to admit **subjective conscious volition acting on the physical world**, invoking a **biologically, psychically and cosmologically symbiotic universe**, rising to conscious climax which resolves the central enigma of existential cosmology – the nature and role of subjective experience – thus providing a direct solution to the "hard problem of consciousness" and the problem of autonomous volitional will. This is essential for human ability to consciously affect the physical world, personal responsibility and scientific consistency with criminal and civil law on intent. The cosmology is thus entirely consistent with quantum cosmology and empirical neuroscience.

The monograph is three works in one: The key **cosmological discovery**, the **vision quest** to unveil it, and a fully-referenced **research report**. Since its inception in June 2021, in my entheogenic mushroom [moksha](#), it has recorded the entire ensuing discovery process, transparently in real time, as it has been realised and communicated, so that the reader can map out and follow a similar trajectory should they desire, or decide to do so. It is carefully designed, not to be accessibly facile, but to provide the full discovery account, as a Rosetta Stone, translating all aspects of the existential cosmos in which we consciously exist, consisting of both the physical universe and the abyss of our conscious experience.

Saving the Diversity of Life from Mass Extinction

The central purpose of symbiotic existential cosmology is not just to reveal the cosmology of the universe in which we consciously exist, but to **save the diversity of life on Earth** from a **human-induced mass extinction** (Leakey & Lewin 1995, Kolbert 2014, Dawson 2016). It thus seeks to directly address our primary existential threats as a living species, healing climate crisis, habitat destruction, species extinction, eradicating nuclear and biological weapons of mass destruction.

It unveils a living cosmology which shows humanity that our central and sacred purpose in existence is protecting and unfolding the immortal diversity of conscious life in the universe. In this sense, it is the therapeutic remedy of both our existential dilemmas, one scientific in terms of our place in the universe and the other spiritual, in the sense of our immortal redemption, invoking the epoch of long-term future goodness, fulfilling both the messianic and fertility quests in immanent transcendence over both. This approach is necessary to transform the spiritual zeitgeist in the scientific age.

Existential Reality and Subjective Conscious Volition over the Universe

The reality of our existence is that, **subjective consciousness is primary**, although the **universe is necessary**. The way we experience reality is that we are subjectively conscious and 100% of our experience of the world and of our dreams and reflections arises from subjective consciousness. All our experience of the physical world is inferred from our conscious sensory experiences of it, although we come to realise it is necessary for our biological survival. Furthermore we are able, through our subjective experiences, to choose to act wilfully and intentionally upon the physical universe to survive.

This means that, to develop an existentially meaningful and correct description of the cosmos, involves first accepting this generative relationship, in interactive social recognition, by first affirming to one another that we, as **subjective conscious sentient beings** have **efficacy of volition over the physical universe**. Once we have agreed this interpersonally, we can explore by scientific experiment, how this interactive subjective-objective process occurs in the physical universe in our brains, genes and molecular interactions. Thus existential cosmology is animistic in the sense that it is derived as an affirmation between live conscious agents, just as in criminal and corporate law of intent, and in how compacts and contracts of trust are negotiated. If we try to reverse the generative existential order and explain existential reality from the physics alone, and its assumed biological causalities, we end up stuck with the **hard problem of consciousness**, that **no purely objective physical process can explain subjectivity** itself, or **intentional volition**, leading to sterile impasse.

Symbiosis and Enlightenment

Symbiotic Existential Cosmology is a profoundly evolutionary cosmology, in which the evolutionary unfolding of life's diversity ensures the biosphere as a whole retains climax stability of unfolding at the edge of chaos, over cosmological time scales. Of the three words in the title "Symbiotic Existential Cosmology", the first word, symbiotic, is the key and only qualifying adjective describing existential cosmology. Symbiosis is the ultimate expression of physical, biological and conscious interrelationship of becoming, in which conscious life in the universe comes to co-existential climax. It is thus natural complexity expressed in full conscious enlightenment fully integrated with life as a whole.

The Conscious Universe

Symbiotic existential cosmology transcends both materialistic and theistic world views:

- (a) It **transcends scientific cosmology** because it **completes the scientific description of nature** by fully **incorporating subjective consciousness** and the **efficacy of volitional will** to affect the physical universe.

(b) It **transcends religious cosmogony** by **transferring cosmological agency** directly back to **humanity and natural life**, verified by **conscious affirmation of our volitional agency**, rather than dependence on supplicant beliefs.

It has three core cosmological principles, **biogenic**, **panpsychic** and **sybiotic**. Life exists in the universe because the laws of nature arising from cosmic symmetry-breaking are fractal, giving rise to living systems as an interactive climax. It is consistent with empirical neuroscience but says that **subjectively conscious physical volition is real**, and this implies some matter – our brains – have physically efficacious subjectivity and hence **all matter, has primitive subjectivity** because brains obey the same laws and forces as other normal matter. Primitive subjectivity thus occurs in quanta and butterfly effect systems which amplify quanta, like storms, and in bacteria and archaea. But a discrete **emergent transition** occurred in the **eucaryote endosymbiosis** between archaea and bacteria, when full attentive consciousness arose in the first single-celled amoeboid-flagellates, forming societies communicating by neurotransmitter molecules such as serotonin. This form of quantum sentience evolved into our conscious brains, as societies of 10^{10} tightly coupled amoeboid cells communicating by the same processes.

Humanity and the Biosphere

Humans evolved to be an environmentally destructive dominant species, because of our evolving Machiavellian social intelligence, after a long period of increasingly rich evolution to climax diversity following the Tertiary-Cretaceous extinction. This shaped our minds to be strongly egotistical to succeed against one-another. In the gatherer-hunter phase, this tendency was moderated by two factors: (1) *the mating mind* – astute female reproductive choice for smart resourceful entertaining and protective males who can engage fulfilling sex to demonstrate genuine indicators of fitness and sensitivity and (2) *original virtue* – the evolution of verifiable trust through long-term personal judgment of good character. However, with the growth of large urban societies, this became overthrown by the imposition of patriarchal domination of woman and nature. Humanity is thus still a dominant species wrecking the biosphere through egotistical tragedy of the commons. Moreover gene-culture coevolution, with the emergence of language, religion, commerce and science hasn't resolved this, because cultural evolution is even more rapid than genetic evolution and has produced no stabilising factors. Only a cosmology in which gene-culture-biosphere co-evolution is complete can resolve this.

Complementary Conscious Cosmology

If we start with the physical brain and try to understand subjectivity, we end up with the **hard problem of consciousness** – the explanatory gap, that no brain process manifests the subjective aspect of conscious experience, that is universal to our awareness of ourselves and the world around us. This appears to be an irreducible problem – objective properties and processes simply cannot of themselves manifest conscious subjectivity. Once we reverse the logic, we discover that **matter has a subjective complement**. So the brain as a whole has subjectivity. But then it's a physical property, not just a biological product of complexity, so its universal, or more accurately cosmological.

This means all quanta have what we describe as subjectivity and volition:

- (1) **Quantum Subjectivity:** Any wave function in the wild is a history and future of real or potential entanglements, forming a type of “consciousness” of the quantum's world, past, present and future – i.e. a global representation of the entire relationship.
- (2) **Quantum Volition:** For a single quantum measurement the outcome is uncertain because the particle can end anywhere within the non-zero wave function without causal conflict. The only constraint is that, on repeated independent identically distributed measurements, the probability of where a particle ends up is defined by the power of the wave function at that point. But probabilities don't determine any individual path, so each quantum has free will to end up anywhere and clearly uncertainty makes a choice.

Primitive Cosmological Subjectivity: This form of subjectivity is co-eval with the nascent universe. Because it's subjective, we can't see its manifestations directly but they help explain why the world looks semi-classical because quantum systems can then also act as “observers”. So we end up with a dynamic quantum universe in a partial state of collapse of its wave functions with new superpositions emerging all the time. This means quantum and unstable quantum sensitive phenomena can exhibit this subjectivity and “free will” e.g. in tornadoes, hurricanes, biogenesis and simpler prokaryote life forms.

Discrete Conscious Emergence: The **eucaryote endo-symbiosis**, in which a species of archaea incorporated respiring bacteria to become our mitochondria, resulted in a completely new phenomenon – attentive sentient consciousness – when the cell membrane became freed from respiratory electron transport, enabling it to become a sensitively dependent sentient excitation at the edge of chaos involving quantum sentience of photons, vibrations and electric fields, with neurotransmitters also enabling social signalling. This emergent aspect of consciousness as we know it, occurred in a discrete topological transformation of the nature of the cell, and in turn, it utilises primitive subjectivity to manifest consciousness in a vastly more coordinated form in all eucaryotes and in our personal experience.

Organismic Consciousness: Complex mammalian brains, including our own, consist of intimately coupled societies of amoeboid-flagellate cells communicating via the same membrane excitability and social signalling molecules they used to ensure the survival of the collective single-celled organism. The brain thus acts as an integrally coupled form of cellular consciousness through edge of chaos phase coupled neurodynamics forming a contextual boundary condition, shaping primitive subjectivity

to evoke the environmental context essential to the organism's survival and procreation. Primitive subjectivity is thus shaped into the conscious experiences we have through the constraints imposed by the brain as filter rather than as a deterministic physical process. This replaces the idea of physical causality in the brain, in a causally closed universe that directs subjective consciousness as a mere internal brain model, with a causally open quantum uncertain universe, in which the the brain state provides the environmental boundary conditions through which conscious experience can anticipate existential crises and has efficacy of intentional volition over our physical circumstances in conscious intuition and decision-making.

Biospheric Symbiosis

Notwithstanding that the diversity of life is a matter of tooth and claw, it is still symbiotic within the biosphere as a whole. As organismic evolution diversifies into plants animals, predators and prey and parasites and hosts, in which there are also climax symbiotic relationships cellular and viral, the genetic symbiosis of the two sexes, and major instances such as mycorrhizal symbiosis between plants and fungi, life is biospherically symbiotic, because natural selection occurs in biospheric feedback and all species depend on the biosphere for survival, so it's a case of survival of the fittest biospheric symbionts, not just species dominance. We can see this in the way predation acts to avoid the herbivores becoming extinct by eating out their plant species, in boom and bust, leading to famine, complemented by the way insect predation favours plant diversity. Instead of going to hell in a basket towards a human extinction, as we are now as a dominant species violating biospheric symbiosis, by regaining symbiosis over evolutionary time scales, humanity inherits its true cosmological meaning and purpose to protect life immortal, to ensure our own evolutionary survival, regaining the perennially immortal future of our 3.5 billion year tenure in the universe.

Moksha

When the brain is cycling in a state of sensory withdrawal in "neutral" in deep meditative and/or entheogenic states, subjectivity can approach a cosmological form in its own right in which the organismic boundary filters defining our conscious awareness become relaxed which we experience as moksha, asymptotically approaching ultimate reality, described in the Upanishads as Brahman, or cosmic consciousness. Our individual conscious experiences in organismic consciousness are thus forms of cosmic consciousness encapsulated by the contextual filters applied by the brain, in which we become climax manifest forms of subjective consciousness interacting through physical volition.

Cosmological Symbiosis

Enter the biospheric response. The same climax period gave rise to plant and fungal species 'salting' the Earth with variants of neurotransmitter molecules which tweak key pathways modulating human perception, mood and survival. In particular, the serotonin analogues called psychedelics – "psyche-revealing" – paradoxically cause (1) a sensory flood, in which the brain begins to develop an internal model of its own processing and (2) quantum change experiences, resulting in ego loss and the experience of "ultimate reality" referred to as "divinity", leading to alleviation of mortal angst in terminal illness and a deep sense of integration with life and nature in the healthy. Hence these are critical to planetary survival, along with other forms of nature meditation and conservation activism.

This means that the physical universe and subjective consciousness are two complementary aspects of cosmological reality, just like the wave and particle aspects of quanta. Mind can't alone make matter and matter can't alone make mind – they are complementary manifestations, like Shiva and Shakti, that make cosmology as we know it possible.

The inclusion of subjectivity opens up the spectres of panpsychism, animism and the mystical/religious quest in the physical universe, because these are all cosmological views, in which consciousness and intentional will is generative and fundamental. However this is a coming of age, in which we as, biota, the living conscious agents of the universe have become the modus operandi, manifesting cosmic consciousness, who thereby must needs accept personal responsibility for our guardianship of all life and our long-term tenure as a/the formative keystone living species in the biosphere, rather than invoking preconceived notions of a creator deity and eternal imaginary heavens and hells to force us into moral compliance, when we know all such notions are simply cultural products of our adolescence.

This is the Weltanshauung of Immortality, which flips the Copernican principle of science, because the privileged view of the universe is conscious life in [paradise on the cosmic equator](#) in space-time, not the mechanistic Sun-centred cosmos or the flat earth with firmaments of Theistic fame. It also flips religion inside out because the sacred purpose of existence is to protect the diversity of life throughout our generations forever, so that conscious life can flower to the point where the universe becomes fully conscious of its own existence through the living biota that form its interactive climax.

Astronomer's paradise: Atacama Desert, Chile
Nicholas Buer/Corbis

Dedication

The accompanying articles, generated out of a single quantum change experience on psychedelic mushrooms, breaking a seven year fast, contain the fabled key to life, the universe and everything – the symbiotic cosmology of perennial conscious existence.

All of us go through life wondering what it's all about, why we are here, and what the meaning and purpose of conscious existence actually is. This is the question always lurking in the backs of our minds, driving our mortal anxiety, from which we try to escape, in futile diversions of power, fame and entertainment until our last moments on our death beds, realising all these things were distractions to avoid the inevitable.

Our current world views are suspended between three contradictory and equally devastating scenarios.

1: **The materialistic scientific view** regards us as merely a collection of atoms and molecules held together by physical, chemical and biological processes. That we are simply our brains and that our decisions are based on our genes and material circumstances over which we have negligible control, because our subjective conscious experiences are simply a model of reality generated by the computational brain, and that free will and personal autonomy are effectively illusions. That there is really no rhyme or reason to existence, and that life is simply an accidental by-product of a universe driven by blind and overwhelming forces, which will eventually annihilate the solar system and all life within it, whether we live a good life, or exploit the others around us and the life of the planet, to our own selfish advantage.

2: **The theistic religious view** claims the universe is a moral test by God; that we do have free will, but are all accursed as sinners by the original sin of Eve, for hearkening unto the serpent. That we endemically fail to heed God's will and that a Day of Judgment will ensue, when the Lord returns to consign us, either to eternal life in Heaven, or a diabolical fate in Hell Fire, forsaking the late planet Earth and the diversity of God's creation in the process. Complementing this is a view of humanity having dominion over nature, to exploit living systems as we see fit, compounded by business-as-usual attitudes, which seek to assimilate all resources and sources of profitability before others take advantage, leading to planetary Armageddon. Likewise **Eastern traditions** lead to the degradation of the Kali yuga, Samvartakalpa or Eon of dissolution – the decline from enlightenment into ignorance.

3: **The living planetary view**: Both materialistic science and theistic religious views are incorrect and dangerously destructive. We are all becoming acutely aware that neither of these scenarios are viable, that the planet is in a worsening state of crisis induced by human misadventure, exploiting the non-renewable resources and living diversity of the planet, resulting in a climate and habitat crisis, causing a mass extinction of the diversity of evolving life, which risks making the world a literal Hell on Earth for future generations, if not precipitating the extinction of our species, risking serious damage to the health and economic viability of ongoing human life.

We now unite 1 and 2 with 3, as overviewed in **three introductions: 1, 2, 3**. These together show how our conscious autonomy and volitional will can be retrieved, how our lives can be fulfilled, what the actual meaning and purpose of life actually is and how the generations of humanity can come to fulfil ourselves in the flowering of conscious existence on evolutionary and cosmological time scales, returning the Earth to the paradisiacal verdancy it harbours in abundance, before it is irretrievably damaged for millions of years to come.

1: → 3: The **scientific sections 1, 2 & 3** elucidate the symbiotic cosmology of the sentient conscious universe, in which conscious life is the climax manifestation. The meaning and purpose of life is then manifest in the immortal flowering of conscious living existence over evolutionary time scales, realising Heaven on Earth, through our integration with the conscious mind-at-large of the universe. The core cosmology has three principles (1) **Biogenic**: Conscious life is the complexity climax of the cosmological structural pathway. (2) **Panpsychic**: Subjective conscious volition over the physical universe means that the subjective mind is universal. (3) **Symbiotic**: Life reaches immortal complexity climax through symbiosis, not dominance of one cultural species.

All eucaryote higher organisms are an endosymbiosis between complementary bacterial and archaeal life forms. Survival under natural selection is how all species maintain perennial symbiosis with the biosphere. Symbiosis is essential for human survival. Symbiosis with entheogenic species, expands spiritual approaches to consciousness, realising the consummation of conscious existence, at the edge of chaos as visionary sexual organisms. Through psychic symbiosis, we can achieve moksha, which in the Eastern traditions signals the escape from the cycle of birth and death, and in the monotheistic traditions constitutes the mystical God-consciousness that has inspired all the founding religious visionaries from Yeshua, through Buddha, to countless shamans and sadhus who have known and appreciated the same secret oracle of existence. Realising cosmological symbiosis.

2: → 3: **Natty Dread** and the **evolution of religion**, section shows the monotheistic eschatological world view leads to an Armageddon destruction of the diversity of life and why Christianity has been, since Yeshua's death, acting in contradiction to his actual vision, perpetuating a false religion based on the dying Son of God, whose flesh and blood we must eat, reappearing as avenging Lord in the Revelation – impeding a paradigm shift from unfulfilled apocalypse to the planetary resplendence of the Tree of Life – evolving Paradise on Earth, the abundant heritage that is our creative destiny, as guardians of the flowering of conscious existence in the universe at large.

To Erwin Schrödinger for the unitary singularity of the conscious mind,
and Charles Darwin for the evolutionary diversity of free will.

Abstract:

This overview summarises the quantum and cosmological physics, evolutionary biology and neuroscience involved in the work “Symbiotic Existential Cosmology” King (2021), *conceived during a quantum change experience on psychedelic mushrooms.*

Symbiotic existential cosmology retains the core features of physical quantum cosmology, while augmenting it to restore the role of **conscious** purposive life in a biodiverse universe into its correct position in the scheme of quantum cosmology. It is thus the actual cosmology of the universe in which we consciously exist, *inverting* the Copernican principle that conscious life does not have a privileged view of the universe. Its symbiotic basis forms a central protection for the **future of the diversity of life** on Earth.

It advances an interlocking set of three cosmological descriptions with incontrovertible evidence, significant consequences and cosmological conclusions:

Biogenic

(a) **Biogenic: Life exists cosmologically as a fractal consequence of the symmetry-breaking of the forces of nature reaching interactive climax.** This gives a correct portrayal of the **cosmological structural pathway** leading from cosmic symmetry breaking to the fractal structure of living matter:

- **Incontrovertible evidence:** Life exists on Earth because the four core quantum forces of nature arising from cosmological symmetry-breaking are non-linear, leading to 100+ chemical elements and fractal molecular structures, from atoms through molecules, molecular complexes such as the ribosome, cell organelles, such as the membrane, cells, tissues, organs, organisms and biospheres, also supported by detailed research in biogenesis (King 2020).
- **Consequences:** Life exists in the epoch of paradise on the cosmic equator in space-time, as the climax manifestation of the structural interaction pathway after first generation stars have made the chemical elements and multicellular evolution has passed the threshold of symbiosis between archaea and bacteria, to eucaryotes and conscious multi-celled animals.
- **Conclusions:** Life has a key cosmological role, enabling the universe to manifest itself, through the subjective consciousness emergent in the biota.

Panpsychic

(b) **Panpsychic: Subjectively conscious volitional will has efficacy⁴ over the physical universe.** This forms a **minimal augmentation of quantum cosmology** to include conscious volition acting on the physical universe:

- **Incontrovertible evidence:** Live conscious human beings experience volitional intent and its consequences in human decision-making acts and behaviour affecting the physical world. A veridical affirmation of this between conscious human beings leads directly to the conclusion that at least some states of matter, (our brains), are complemented by a subjective aspect having a physical effect (the conscious volitional mind).
- **Consequences:** Affirmation of human subjectively conscious physical agency and legal responsibility of intent. Occam's razor is reversed, eliminating pure materialism, as inconsistent with subjectively conscious physical volition. The physical universe and hence the brain, is not causally closed due to quantum uncertainty, enabling subjective consciousness to seamlessly participate in volition during the uncertain instabilities of coherent processing without resulting in neurodynamic causal conflict.
- **Conclusions:** (1) Because brains are normal matter, obeying the four core quantum forces of nature, even if they display additional properties such as quasi-particle states, the subjective aspect is a property of normal matter, and thus complementary to the universe as a whole, extending wave-particle complementarity. Primitive subjectivity thus exists in quanta, unstable edge of chaos quantum systems, biogenesis and prokaryotes. (2) **Conscious sentient volition arises in eucaryotes in a discrete emergent transition**, due to the archaeal-bacterial eucaryote endosymbiosis freeing the cell membrane for sentient excitability and social signalling.

Symbiotic

Moray eel and cleaner shrimp

(c) **Symbiotic: The planetary biosphere survives and achieves climax diversity through ecosystemic symbiosis, upon which human survival is dependent.** This details how **edge of chaos quantum dynamics** results in organismic, biospheric, psychic and cosmological **symbiosis as a biodiverse consummative climax**:

- **Incontrovertible evidence:** Humans and all eucaryotes are multiply symbiotic organisms by (i) mitochondrial endosymbiosis between the root archaeal and bacterial lineages, (ii) sexually antagonistic genetic coevolution, (iii) nuclear-transposable element genetic symbiosis, (iv) symbiosis involving natural selection of predators and prey, parasites and hosts, in biospheric sustainable evolutionary feedback and (v) human symbiosis with our co-dependent food, and medicinal co-species, which we are currently violating in a mass extinction of biodiversity.
- **Consequences:** First person visionary experience in **psychic symbiosis** with our psychedelic co-species.
- **Conclusion:** The universe becomes able to manifest, know and realise itself consciously, in **cosmological symbiosis**, through entheogenic experiences complemented by meditative practices.

(d) **Survival Necessity: Biospheric symbiosis is necessary and essential for human survival.** Homo sapiens can survive on evolutionary time-scales only by being evolutionarily successful as a biospheric symbiont. Currently it is not. This is the motivating necessity to act, imbued by the mushroom experience, which is itself a product of biospheric evolution of substances conducive to psychic symbiosis, and is manifestly true as a principle of long-term survival of both humanity as a species and the diversity of life in the biosphere.

⁴ *efficacy* – the ability to produce a desired or intended result. Latin: *efficere* accomplish.

Introduction:

The Symbiotic Cosmology of Perennial Conscious Existence solves (a) the **hard problem of consciousness** – how and why we have subjective conscious experiences, (b) the **problem of volitional will** – how conscious intentionality can have real effect in the physical world and (c) the **central enigma of existential cosmology** – the cosmological role of life and conscious experience in the universe.

In pure materialistic physical cosmology, consciousness is a passive **epiphenomenon** of material brain function, as a biological computational mechanism. Volitional will is thus regarded as an illusion in a putatively causally-closed objective universe. In theistic cosmology, people possess free will, but the universe is created by God as a moral test of “sin” with divine punishments, in which the ‘real’ life is in eternal Heaven or diabolical Hell, discarding the “late planet Earth”. Eastern traditions likewise invoke moral karma and an almost unachievable goal of subjective enlightenment, leading to the need for reincarnation, as primary realities over nature and suffering descent into the Kali Yuga.

Although we are fully aware of the existence of the physical universe and are obliged to accept the laws of nature and their impacts on our biological bodies and lives to survive, the entirety of our access to the world comes sine qua non through our subjective conscious experience, both consensually in our shared everyday experiences of the physical world around us and individually through dreams, memories, reflections and entheogenic visions. Moreover, absolutely critical is the fact that subjectively conscious agency is expressed in conscious volitional will affecting the world around us through our actions, via our physical brain. To be valid, cosmology must successfully explain both the objective and subjective aspects of experiential reality.

Symbiotic existential cosmology makes a **minimal augmentation to the standard model of quantum cosmology** to fully incorporate subjective decision-making to form a concise, complete and consistent description of existential reality, consistent with **quantum reality, biological evolution** and empirical **neuroscience**. Because it is centrally based on a universe in which the structural interaction pathway leads to edge of chaos climax of living diversity, it has very significant implications for the biodiverse future of planet Earth in a time of **climate and biodiversity crisis** involving an **immanent human-caused mass extinction of life** (Leakey & Lewin 1995, Kolbert 2014, 2021), which could seriously compromise or even extinguish the future of the human species.

It also has very significant implications for **society as whole**, because it supplants both a **purely materialistic scientific cosmology** and the **monotheistic, and Eastern religious models**, in favour of a fully **biodiverse cosmology** critical to **planetary survival**. Its validity is **established veridically** by conscious observers, by Occam’s razor, to be the **only class** of cosmology **consistent with subjective decision-making autonomy**. The **cosmology** has three interlocking components: (1) **biogenic** (2) **panpsychic** and (3) **symbiotic**.

1. Fractal Biocosmology: This constitutes an **indisputable empirical fact of cosmological evolution**.

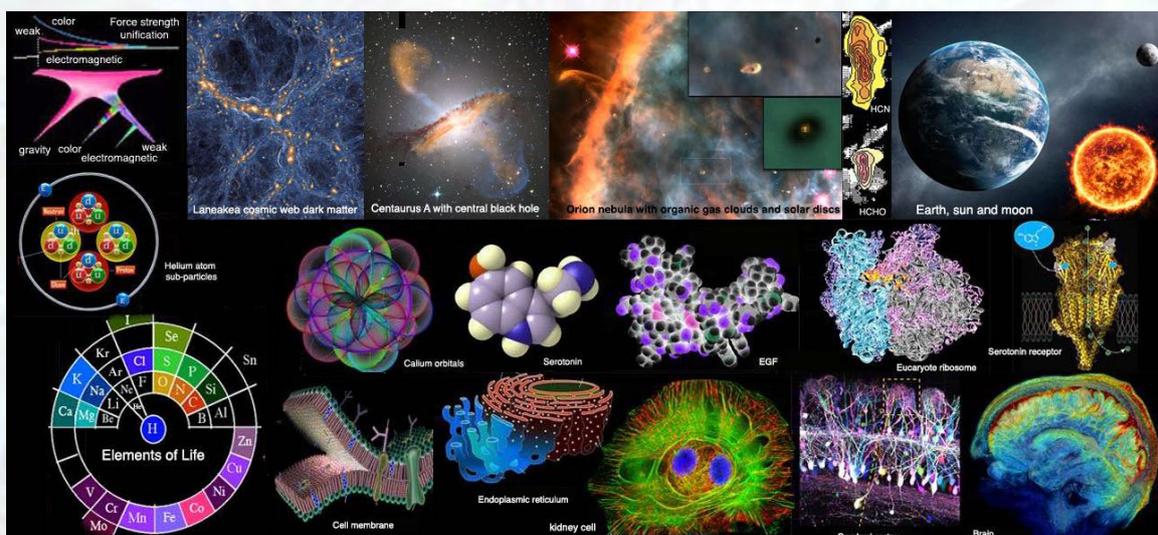

Fig 1: **Top row:** The cosmological **energy pathway** runs from the inflationary phase, to the cosmic web, galaxies and black holes, gaseous nebulae, stars and planets to an eventual big rip, crunch or heat death. **Lower rows:** By contrast the **structural pathway** to complete interaction of the four forces of nature induced by cosmic symmetry-breaking involves quarks, hadrons, atomic nuclei, a secondary symmetry-breaking of the periodic table, to form the elements of life. The molecules of life form quantum fractals physically and biodynamically, molecular complexes, organelles, cells, tissues, organs such as the brain, and organisms.

While the **energetic pathway** of the cosmological process leads to galaxies, stars and solar systems driven by the most powerful of the four forces, leading eventually to a big crunch, cosmic bounce or expanding heat death, the **structural interaction pathway** of the four quantum forces together in full integration on the negentropic planetary surface, leads to fractal molecular structures, organelles, cells, multicellular tissues and organs such as the brain, organisms and the evolving biosphere. This sequence is the **pathway to quantum complexity** induced by the cosmic symmetry breaking of the forces of nature, complementing the **energy pathway – in paradise on the cosmic equator** (fig 2 right).

Research has also revealed natural pathways to biogenesis, fully discussed in King (2020). Fig 2 illustrates three features of this research ongoing worldwide, illustrating the diversity of organics found in primitive syntheses and carbonaceous chondrites whose elementary components are also evidenced in the HCN and HCHO clouds in fig 1, the lost city vents which demonstrate a far-from equilibrium process on the ocean floor capable of supporting molecular biogenesis and concentrating the ingredients 1000 fold to biological concentrations and an example one-pot reaction producing a complementary suite of nucleosides.

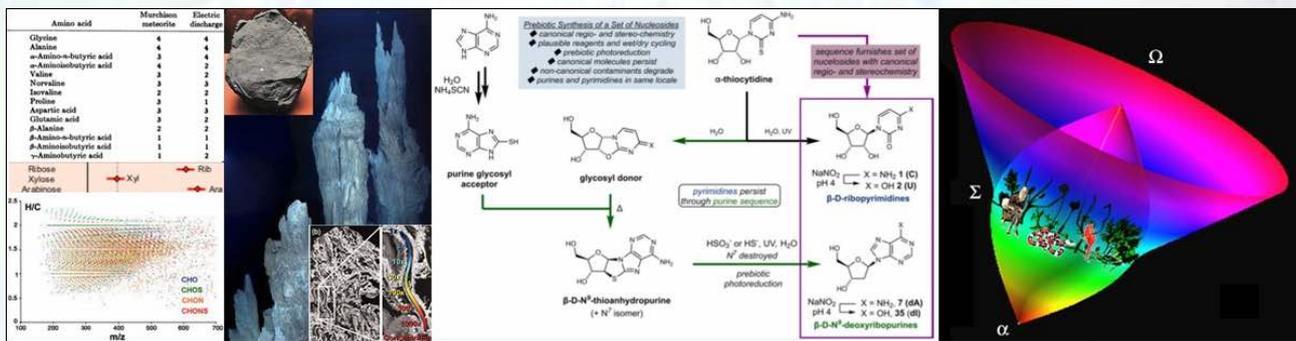

Fig 2: (King 2020) Components of the link from organics in the universe to the origin of life on Earth. Left: Murchison carbonaceous chondrite (inset), major amino acids and sugar components, the sheer diversity of organic products. Centre left: Lost city vents formed by a chemical garden reaction between basic olivine and acidic sea water with dissolved CO₂. Resulting H₂ and CO can drive the formation of organics including C1-4 hydrocarbons. Organics can be concentrated to biological levels (lower). Centre right: A one-pot synthesis leading to both ribo-pyrimidine nucleosides (U, C) and deoxyribo-purine nucleosides (A, I) (Xu et al. 2020), an ingenious single-phase process capable of generating both U and C and deoxy purines dA and dI (inosine) which form two pairs of complementary binding purines and pyrimidines, thus forming in one step a four member alphabet for complementary replication. Far right: While the cosmological energy pathway leads from α to Ω the heat death or big rip, crunch or bounce, the structural interaction pathway leads from α to Σ, facilitated by anthropic constraints on the time for first generation stars to form the chemical elements plus the time for the evolution of life on Earth (Carter 1974, Barrow & Tipler 1988, Lemley 2000).

This means that **life is a central cosmological phenomenon** and not irrelevant to physical cosmology.

2. Darwinian Panpsychic Cosmology is a minimal revision of physical cosmology **consistent with quantum mechanics**, in which the **subjective aspect of reality is complementary to the universe** as a whole.

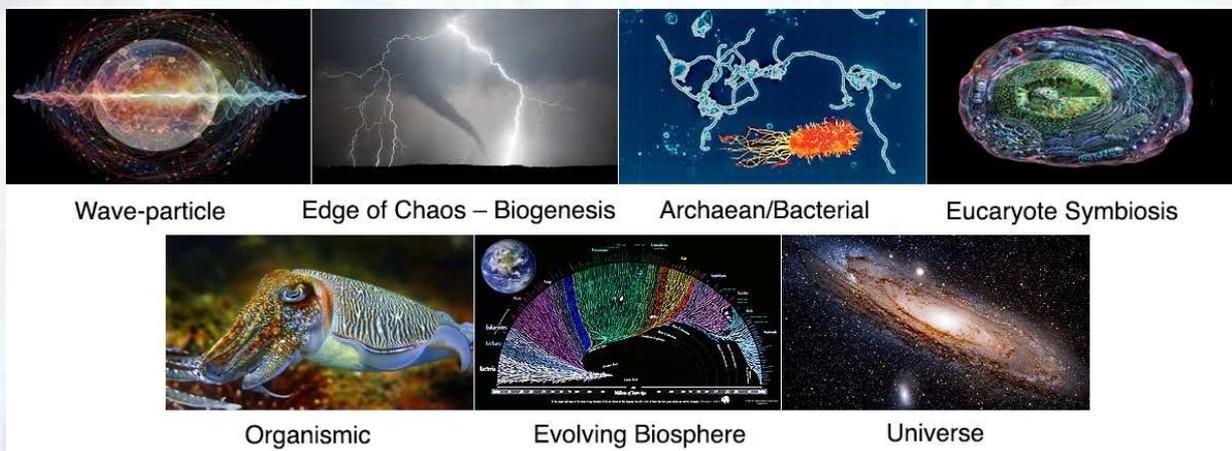

Fig 3: Overview of classification of graduated subjective aspects of existential cosmology.

In this picture (a) all wave-particle quanta, (b) Gaia systems: highly unstable quantum processes, including edge of chaos, self-organised criticality, and biogenesis (c) prokaryote archaean and bacterial excitable cells, (d) eucaryote cells with signalling membranes capable of sentience (e) living organisms with excitable neurodynamics and (f) evolution, where each mutation is a quantum instance, all inherit subjective aspects and (g) the universe does also through the biota as the most complex physical manifestations of the four forces acting together with conscious edge of chaos coherence ⁵. In philosophical terms, primitive phenomenal consciousness (a) – (c) is universally panpsychic but the transitive structure of sentient consciousness (d) – (e) is emergent. This form of panpsychism involves only root subjectivity, with brain dynamics as a boundary condition, moulding how this is shaped as a whole as the subjective stream of conscious experience, so it does not require the detailed analysis of how subjective qualia that arise in pan-protopsychist theories are composed.

It is named after Charles Darwin because it is an evolutionary classification pivoting on the eucaryote endosymbiosis, which is consistent with Darwin's own view of free will:

"To see a puppy playing [one] cannot doubt that they have free-will" and if "all animals, then an oyster has and a polype." (Darwin)

It is the **only class of cosmology in which subjective experience and volitional will are fully included and correctly represented**. Once we accept subjective autonomy and volitional will into the description, the fact that the subjective mind interacts with the objective brain to realise decisions, means that subjective consciousness acts upon the physics of the universe. But the brain also obeys the core model of the four quantum forces of physics, so subjectivity becomes a feature of the universe as a whole. Thus personal conscious autonomy implies encapsulated panpsychism. This implies the complementary subjective aspect – the mind at large – is a single entity, complementary to the universe in the multiple encapsulations we experience as organismic consciousness, having volitional will to affect the world around us, consistent with a Tantric – mind complementing matter – origin.

"There is obviously only one alternative, namely the unification of minds or consciousnesses. Their multiplicity is only apparent, in truth there is only one mind. ... I should say: The overall number of minds is just one" (Erwin Schrödinger).

In a single quantum, primal subjectivity arises from the wave function implicitly encoding the well of quantum entanglement of the quantum's past and future under special relativistic quantum mechanics and quantum will is the uncertain idiosyncrasy of a single quantum instance, as illustrated by Schrödinger's cat being both alive and dead until the experimenter opens the box and finds either a live or a dead cat.

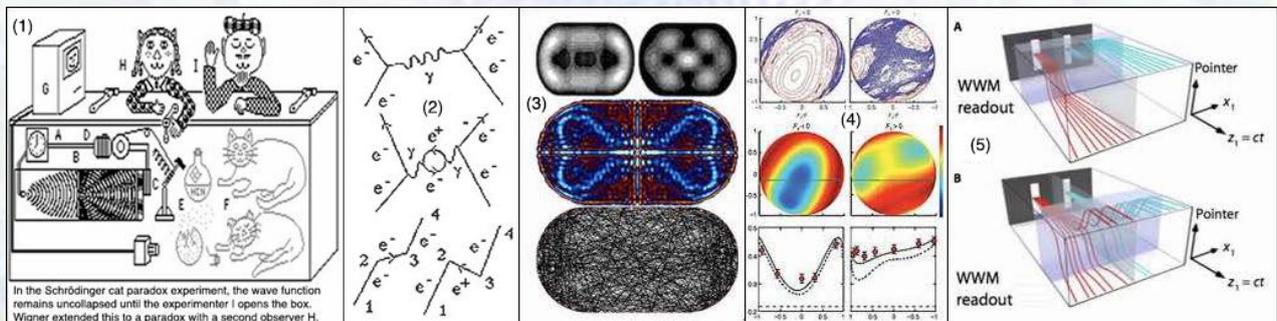

Fig 4: (1) Schrödinger cat experiment. (2) Feynman description of quantum field theory (QFT) involves all possible interactions of particles via a wave-theoretic propagator function, in which the force field is mediated by all conceivable virtual particles appearing and disappearing within uncertainty. This is also special relativistic, so involves both past and future information, so that as shown below electron deflection, if time reversed becomes electron-positron creation and annihilation. (3) Quantum stadium illustrates suppression of chaos in closed quantum systems. Top: Experimental realisation of scarring of the wave function around wave eigenfunctions, biasing the probabilities around unstable classical repelling orbits. Mid: Cellular automata simulation (King 2013). Bottom: Classical ergodic chaotic trajectory. (4) While the classical kicked top (above) shows similar regions of chaos to (3) in the (top), the quantum kicked top (middle and bottom) shows chaos inducing entanglement with nuclear spin (Chaudhury et al. 2012). Entanglement between the electron and nuclear spins is quantified (bottom) by the linear entropy, of the electron reduced density operator. (5) Experiment confirming the existence of surreal Bohmian trajectories (Mahler et al. 2016). Conceptual diagram of the result of reading out the which-way measurement (WWM) in a double-slit apparatus in the near field (A) and in the midfield (B). Colour indicates the slit of origin of a Bohmian trajectory, and vertical position indicates the result of the WWM. This surreal behaviour is the flip side of the demonstrated nonlocality, due to the entanglement of the photons, which, in Bohmian mechanics, makes their evolution inseparable even when the photons themselves are separated. Because entanglement is necessary for the delayed measurement scenario, this nonlocal behaviour is to be expected and is the reason for the surreal trajectories.

⁵ The cosmic web has also been raised as a possible source of fractal complexity (Vazza & Feletti 2020).

Because quanta may be also able to act under certain circumstances as interactive “observers”, the universe is also potentially able to collapse its own wave functions, with human observer collapse just being a special case acting on unstable brain states. The multiverse thus becomes a real universe with an ongoing history, as we perceive it. This picture is one in which new branches are being created in the wave function through quantum superposition, while others are being collapsed by conscious measurement, resulting in dynamic evolution of the cosmic wave function. Special relativity, the most “classical” part of quantum reality, is implicitly retrocausal as well as causal, as in Feynman diagrams, so quantum reality is implicitly anticipatory, involving transactional collapse across relativistic space-time in which a network of potential transactions become one or a set of real emitter-absorber interactions.

In the pilot wave interpretation (Bohm 1952), the wave guides the particle, which is in an arbitrary but definite extant position, however it does not describe particle creation and annihilation in the Feynman picture. In standard quantum mechanics the position of the particle is uncertain and the amplitude of the wave function determines the probability of the particle being in any position. In the SEC description, uncertainty is not irreducible randomness but is a measure of deep quantum entanglement, complemented by the subjective aspect. This determines the position in the pilot wave model and defines “collapse” of the wave function in standard quantum mechanics and is consistent with both.

Fig 4 illustrates two experiments pertinent to this point of view. While closed quantum systems whose classical variants, such as the stadium billiard, are chaotic with ergodic unstable orbits, the quantum version shows suppression of chaos in the wave function probability distribution clumping around unstable periodic orbits. However when the quantum system is able to interact with other modes, as in the kicked top, the chaotic regime results in entanglement with additional factors, in this case nuclear spin, showing that quantum chaos induces entanglement. This shows us that all forms of decoherence due to interaction with other wave-particles at non-zero temperatures can simply generate further forms of quantum entanglement.

In the second experiment, surrealistic Bohmian trajectories under weak quantum measurement, where the delay to the retrodictive (time backwards) observation is varied, show that there is no inconsistency between the Bohm interpretation and standard QM because the surreal orbits in Bohm’s interpretation correspond to entangled states in QM. This provides a basis for the SEC interpretation to be consistent with both.

Coherently unstable edge-of-chaos quantum systems, biogenesis and the dynamics of excitable archaea and bacteria inherit coherent forms of panpsychism in a primitive form of subjectivity, prior to attentive consciousness, coherent with the description of Hunt & Schooler (2019). Many natural phenomena, take the form of edge-of-chaos processes, such as wind, waterfalls, thunder and lightning storms, from turbulent mountain summits to the ocean, which from the point of view of Symbiotic Existential Cosmology are strong candidates for primitive coherent subjectivity, consistent with earlier animistic views preceding religious beliefs.

These systems and the ensuing ones in single-celled eucaryotes and multicelled animals all inherit the capacity to avoid approach to the classical, macroscopic limit, as they are processes which are not IID systems generated by independent and identically distributed measurements (Gallego & Dakić (2021). Similarly, in quantum electrodynamics, in which the stochastic aspect corresponds to the effects of the collapse process towards the classical limit ⁶, consciousness has been proposed to be is represented by the zero point field (ZPF) (Keppler 2018, 2021), of the quantum vacuum in quantum field theories and the quantum dissipative theory (Freeman & Vitiello 2016).

Subjective consciousness is emergent in a **single discrete transition**, occurring as a result of eucaryote endosymbiosis, when respiratory energy was sequestered in the mitochondria (Wan & Jékely 2021) , and the excitable cell membrane became available for signalling and perception of quantum modes, including vision (photons), hearing (phonons), smell (chemical orbital perturbations) and touch (physical torsion). This became preserved and elaborated by evolution because it anticipated threats to survival, in an excitable organism lacking a computational nervous system.

This process is illustrated in detail in fig 5, where the free-living excavate *Naegleria gruberi*, regarded as a candidate organism close to the eucaryote root, demonstrates the presence of excitability, adaptive behavioural modes, including

⁶ The approach of SED is guided by the hypothesis of the existence of the (random) zero-point radiation field, ZPF. This rather more elaborate approach goes through a statistical evolution equation in phase space, to arrive at a description in x-space, in which the dissipative and diffusive terms are seen to bring about a definitive departure from the classical Hamiltonian dynamics.

amoeboid and flagellate habits, key signalling processes including G-protein-linked receptors, kinases and second messengers characteristic of higher animal nervous systems, cryptic sexuality, actin and microtubule activity.

This process takes another quantum leap at the interface between social single-celled social eucaryotes and multicellularity, where membrane excitability, neurotransmitters, action potentials and synaptic genes arose in single celled eucaryotes in parallel by the time of the transition from choanoflagellates to metazoa, with the action potential arising as a response to existential crisis, shared by flagellar eucaryotes spanning all branches of the eucaryote tree, along with synaptic genes involved in membrane binding in colony formation in choanoflagellates and related protists (Burkhardt & Sprecher 2017). Each of these cells can release transmitters that act on receptors in nearby cells to produce movements of the whole colony. A similar response in sponges causes release of GABA and nitric oxide (NO), (Kristan 2016).

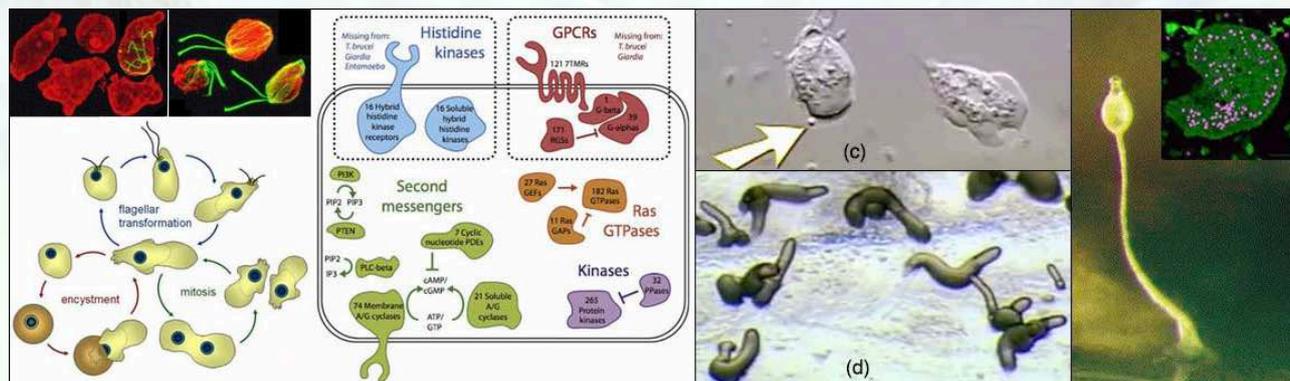

Fig 5 (a) Life cycle and (b) complement of signalling systems found in *Naegleria gruberi* (Fritz-Laylin et al. 2010), a free-living single celled bikont amoeboid-flagellate, belonging to the excavata, which include some of the most primitive eucaryotes such as *Giardia* and *Trichomonads*. Nevertheless it is capable of both oxidative respiration and anaerobic metabolism and can switch between amoeboid and flagellated modes of behaviour, regenerating complete centrioles and flagellae de novo (Fritz-Laylin & Cande 2010). The *Naegleria* genome sequence contains actin and microtubule cytoskeletons, mitotic and meiotic machinery, suggesting cryptic sex, several transcription factors and a rich repertoire of signalling molecules, including G-protein coupled receptors, histidine kinases and second messengers including cAMP. One strain analysed is a composite of two distinct haplotypes, indicating hybridization. Although sexual mating has not been observed in *Naegleria*, the heterozygosity found in its genome is typical of a sexual organism, with perhaps infrequent matings. Additionally, identification of the core RNAi machinery indicates that *Naegleria* may use this mechanism. (c) Individual foraging behaviour of *Dictyostellium discoideum* with bacterium about to be eaten. (d) Motile worm stage involving coordinated excitable organismic behaviour of around 1000 amoebae together to find a good location to form a fruiting body. Right *Dictyostellium discoideum* fruiting body. Inset: Sexual syntinium with multiple nuclei, pink (Bloomfield et al. 2019). The two modes of activity show this organism has both an individual mode of sentient behaviour and an organismic mode in which activity results in coordinated excitable motion, for the collective benefit of the society of individuals to the sacrifice of the non-sporulating individual's forming the fruiting body stalk. These forms of sentient behaviour arose in single-celled eucaryotes a good billion years before computationally capable brains evolved in metazoa.

The major neurotransmitters, such as serotonin arose as social signalling molecules in single celled excitable eucaryotes tuned for collective survival of the social organism, rather than individual cellular survival. Serotonin, in particular has both a developmental and a signalling role, conserved all the way from cellular slime moulds to humans. In myxamoebic *Dictyostellium*, serotonin and MAOA form the organiser of aggregated fruiting buds and in humans serotonin is involved in organismic brain development, from the neural groove all the way to ascending 5HT1b serotonin pathways, providing the signals that determine the correct five layers of the cortex for neuronal migration (Lauder 1993, Witteveen 2013). The brain has thus evolved as an intimately-coupled society of amoeboid-flagellates communicating by the same social signalling molecules we find in single celled eucaryotes, such as serotonin, glutamate and GABA, the latter two of which are cosmologically abundant, as noted in fig 2.

In multicellular animals, subjective consciousness was retained because of its capacity to avoid primary risks of death by anticipating predatory attacks and became seamlessly incorporated into edge-of-chaos nervous system processing, in which brains effectively became closely coupled societies of excitable cells communicating by the same social signalling molecules found in single celled eucaryotes. This enables subjective consciousness to be modulated by the physical forms of brain processing, invoking the subjective model of reality and the differing quantum sense modes such as visual (photonic) and auditory (phononic) and olfactory (orbital), thus resolving the forms of qualia as a product of the seamless integration of the subjective aspect moulded by neurodynamical processes, with volition intervening in uncertain unstable dynamical states at the edge of chaos.

Objective and Subjective Empiricism Empiricism has two complementary modes verified empirical observation as in objective natural science and affirmed empirical experience between conscious individuals. Both can be analysed by statistical methods. The physical universe is easily interrogated on most fractal scales thanks to Galileo's telescope, the microscope and their technological variations. This makes objective validation facile. The subjective realm can only be interrogated subjectively as a whole and we don't even know one another are actually conscious. So we have two direct avenues and several indirect ones. We can interrogate (1) ordinary human subjective states of organismic consciousness and (2) wild states of moksha claimed by experiencers to be cosmic consciousness. Our conscious volitional will is also evident (3) in our capacity to put conscious intent into physical decision-making activity, and we can exchange recognition of this with one another as a foundational veridical transaction affirming this vivacious volition in ourselves and one another. We also use "theory of mind" to impute that other humans are conscious and by extrapolation other mammals. We can also sense the awareness of more diverse species, for example in crickets singing in the long grass and coordinated flashing of fireflies. Darwin said free will goes down to the "polypes" and the symbiotic cosmology says attentive consciousness goes to the eucaryote endosymbiosis. When we watch individual *Dictyostellium amoebae* they act purposefully just like our neutrophil phagocytes 1, 2 and have individual graded EEG-like excitations. Pivotally they make a transition point because they have two excitation modes, one individual and the other coherently organismic at the motile worm stage, so they demonstrate that subjectivity is a function of the coherent physical phenomenon encapsulating the process.

Although it is very difficult for us to see or understand the "consciousness" in single-celled species, they do have purposive behaviour and the active excitable behaviour of single-celled eucaryotes and their biological homology with our own brain excitations and synaptic neurotransmitters indicates the same physical processes are operating.

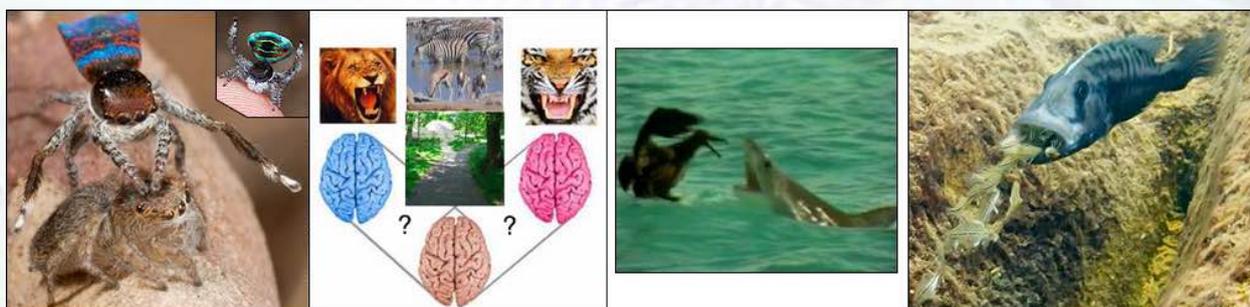

Fig 6: (Centre) The pivotal role of subjective consciousness lies in avoiding lethal attack in prey and starvation in predators, leading to a Red Queen race between conscious organisms similar to the peacock's tail effects of sexual selection. Getting to the water hole either in the savannah or jungle are dependent on immediate intuition of the environmental milieu and are notoriously intractable computationally because the prevailing circumstances of the occasion are undetermined. Left and right: Courtship (peacock spider carefully seducing a female to avoid being eaten) and parenting behaviour (cichlid fish holding offspring to transport to a safer location) across the range of higher animals is also indicative of conscious intent. Although, like birds, these fish can be fooled by cuckoo catfish their careful strategic behaviour to ferry offspring to safer sites shows purposive volitional intentionality.

This means that the foundations of subjective consciousness are cosmological and that the universe is **conscious as a whole, manifest in and through the biota**. This solves the hard problem of consciousness, because the subjective aspect is integral to coherent excitable brain processes. The easy objective problems of consciousness do not solve the hard problem, which is neither confined to neuroscience, nor philosophy, but requires a cosmological paradigm shift.

Uncertainty and mind: The action of mind on brain necessarily arises from modulating the uncertain aspect of quantum indeterminacy in edge of chaos brain processing. This enables volitional will to intervene in the brain without disrupting the partial causal closure of the universe in brain processing in the quantum uncertain universe. In this sense, classical causality is replaced by quantum "consciousness". It provides plenty of room to affect the computationally-intractable uncertain outcomes in evolutionary survival, using both subjective anticipation ⁷ inherited from single celled eucaryotes a billion years before neural systems evolved and historical experience generated by cognitive processes, subjective experience and memory.

⁷ Anticipation is used, rather than prediction, which has a more objective classical implication of declaring, rather than subjectively conceiving. **Anticipation:** late 14c., "foreshadowing," from Latin *anticipationem* (nominative *anticipatio*) "preconception, preconceived notion," noun of action from past-participle stem of *anticipare* "take (care of) ahead of time," literally "taking into possession beforehand". **Prediction:** "act of predicting; a prophecy, a declaration concerning future events," 1560s, from French *prédiction* and directly from Medieval Latin *predictionem* (nominative *predictio*), from Latin *praedictio* "a foretelling," noun of action from past-participle stem of *praedicere* "assert, proclaim, declare publicly".

Darwinian panpsychism thus has similarity to Tononi et al.'s (2015) integrated information theory (IIT) by widening the scope of subjectivity to all systems having coherent forms of quantum instability, along with attentive consciousness in all eucaryotes. However it differs from IIT in that it is not seeking simply an abstract formulation of consciousness as an integrated informational system, which on its own has no subjective aspect, but uses dynamical criteria of coherent instability that interface smoothly with quantum reality, introducing a genuine subjective aspect. It also has similarities to Graziano's (2016, 2017, Webb & Graziano 2015) attention schema theory (AST), particularly in regard to the key role of conscious attention being to anticipate threats to survival. It naturally acknowledges the strength of Graziano's argument that a model of attention itself as a form of self-consciousness is central to this process, but as a vehicle to anticipative conscious volition, not a mechanistic contrivance that fools us into thinking we have conscious volition when it exists in AST only as an AI capable algorithm.

Fig 7 illustrates some of the neurophysiological processes perceived to underlie conscious processing. Walter Freeman's model of olfaction consists of an electroencephalogram (EEG) dynamic oscillating via excitatory glutamate and inhibitory GABA neurons entering higher energy chaos as the animal sniffs. This then falls into one or another attracting basin, as the energy engaged by attention is reduced, thus identifying the odour. In the case of a new stimulus, learning alters the potential energy landscape to produce a new attractor. This type of process, involving an edge of chaos transition to a more ordered state, can be generalised to decision-making situations where the global brain dynamic has an instability between possible outcomes, in which a transition from higher energy chaos leads to the decision/solution. Because edge of chaos dynamics invoke the butterfly effect, this raises the spectre of an unstable global state becoming sensitive to instabilities on descending scales of neural assembly to a single neuron and potentially the quantum level of the ion channel in a neuron crossing its sigmoidal threshold. The concept of stochastic resonance has also been demonstrated to promote such hand-shaking fractal scale transitions in the energetics. This is simply a descriptive overview of possible processes involved, in the face of the failure of promissory materialistic neuroscience (Popper & Eccles 1984) to demonstrate physical causal closure of brain function, so Occam's razor cuts in a direction which avoids conflict with empirical experience of conscious volitional efficacy over the physical universe.

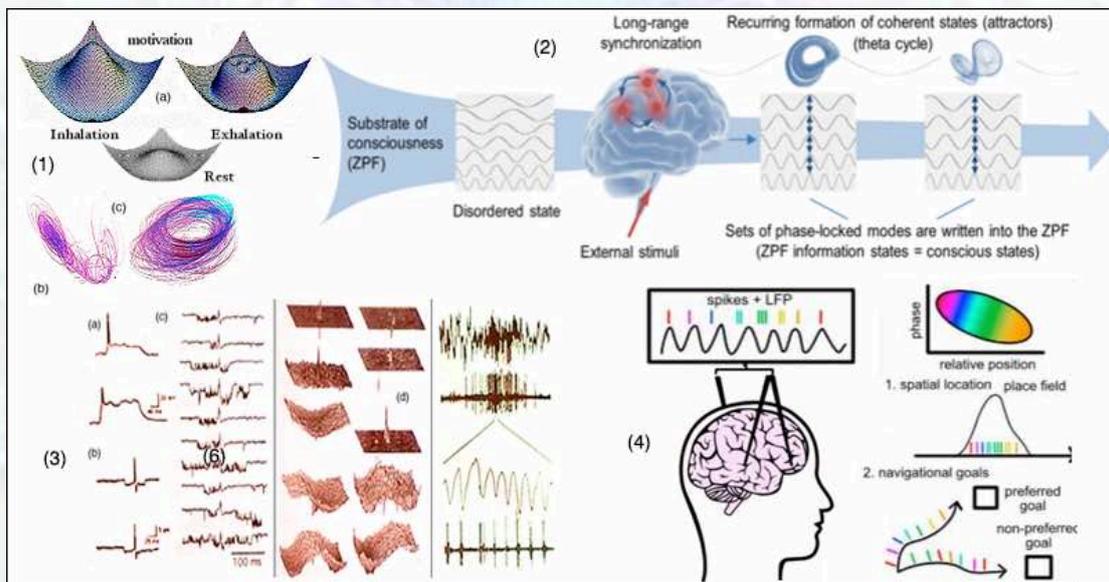

Fig 7: (1) Edge of chaos transitions model of olfaction (Freeman 1991). (2) Joachim Keppler's (2018) view of conscious neural processing uses the framework of stochastic electrodynamics (SED), a branch of physics that affords a look behind the uncertainty of quantum field theory (QFT), to derive an explanation of the neural correlates of consciousness, based on the notion that all conceivable shades of phenomenal awareness are woven into the frequency spectrum of a universal background field, called zero-point field (ZPF), implying that the fundamental mechanism underlying conscious systems rests upon the access to information available in the ZPF. This gives an effective interface description of how dynamical brain states correspond to subjective conscious experiences, but like the other dynamical descriptions, does not solve the hard problem itself of why the zero point field becomes subjective. (3) Stochastic resonance as a hand-shaking process between the ion channel and whole brain states (Liljenström & Svedin 2005). (4) Illustration of micro-electrode recordings of local wave phase precession (LFP) enabling correct spatial and temporal encoding via discrete action potentials in the hippocampus (Qasim et al. 2021).

This is complemented by a second process earlier noted by Karl Pribram (1975, 1993), in which centrally attended (conscious) processes are distinguished from background noise of peripheral processing by the phase coherence of their excitations rising and falling together. Decoherent oscillations are relegated to the periphery of attention while

coherent excitations are central. This is again consistent with competing peripheral excitations vying for central attention in an evolutionary process of natural selection favoured by several neuroscience ideas. This process of phase coherence has striking similarities to quantum uncertainty, where a measurement of energy requires a non zero time interval defined by Planck's constant h to count the wave beats against a reference wave. This model became clearer experimentally, in that the discrete action potentials of single neurons were found to be statistically modulated by the phase precession of the overall voltage wave associated with the EEG (Qasim et al. 2021), thus bringing in a discrete cellular response to the continuous local wave potential, also characteristic of quantum phenomena in the probability interpretation of the particle's position within the wave.

Joachim Keppler (2018, 2021) presents an analysis drawing conscious experiences into the orbit of quantum field theory, based on the conception that the universe is imbued with an all-pervasive electromagnetic background field, the zero-point field (ZPF), which, in its original form, is a homogeneous, isotropic, scale-invariant and maximally disordered ocean of energy with completely uncorrelated field modes and a unique power spectral density. This is basically a simplification of the uncertainty associated with the quantum vacuum in depictions such as the Feynman approach to quantum electrodynamics (fig 4). This does not of itself solve the hard problem of subjectivity, because it is a purely physical model but does provide a basis to discuss the brain dynamics accompanying conscious states in terms of two hypotheses concerning the ZPF:

"The aforementioned characteristics and unique properties of the ZPF make one realize that this field has the potential to provide the universal basis for consciousness from which conscious systems acquire their phenomenal qualities. On this basis, I posit that all conceivable shades of phenomenal awareness are woven into the fabric of the background field. Accordingly, due to its disordered ground state, the ZPF can be looked upon as a formless sea of consciousness that carries an enormous range of potentially available phenomenal nuances. Proceeding from this postulate, the mechanism underlying quantum systems has all the makings of a truly fundamental mechanism behind conscious systems, leading to the assumption that conscious systems extract their phenomenal qualities from the phenomenal color palette immanent in the ZPF."

Although Symbiotic Existential Cosmology doesn't directly utilise any particular quantum interpretation as its basis, it is broadly consistent with both the ZPF description involving a quantum interface between brain dynamics and subjective consciousness, and with the dissipative quantum model of brain dynamics (Freeman & Vitiello 2007, Sabbadini & Vitiello 2019). It demonstrates the kind of boundary conditions in brain dynamics likely to correspond to subjective states and thus provides a good insight into the stochastic uncertainties of brain dynamics of conscious states that would correspond to the subjective aspect, and it even claims to envelop all possible modes of qualitative subjectivity in the features of the ZPF underlying uncertainty, But it would remain to be established that the ZPF can accommodate all the qualitative variations spanning the senses of sight, sound and smell, which may rather correspond to the external quantum nature of these senses. Also the ZPF as a physical manifestation does not itself solve the hard problem as such.

This picture is consistent overall with neural processing being a causally incomplete dynamical system, interfacing with quantum reality at points of environmental, and dynamical instability amid tipping points, making it possible for the subjective aspect associated with conscious volition to interact with the physical brain by forms of internal quantum measurement, without disrupting the extent to which neurodynamical processing is causally determined by the brain.

3. Symbiotic Cosmology arises because natural systems achieve optimal complexity and evolutionary persistence and diversification in symbiotic interactions complementing competition..

This climax of biological evolution arises in eucaryotes as a result of:

- (a) The **eucaryote endosymbiosis** between the two founding branches of life, **archaea** and **bacteria**, resulting in a complexity catastrophe leading to cell organelles and informational excitable membranes communicating through social signalling molecules, with fundamental energy processes sequestered internally in the mitochondria. This results in cellular sentience through interaction with external quantum modes forming the senses.
- (b) At the same time **asymmetric sexuality** evolved as a genetic symbiosis between complementary strains, enabling indexed recombination of large genomes.
- (c) In parallel, **cell-virus/transposable element** symbiosis occupying up to 46% of the human genome, although some members are still actively reproducing in the germ line they have also given rise to modular gene expression. In terms of the selfish gene (Dawkins 1976), transposable elements notwithstanding, organism genomes are one huge genetic symbiosis, through organismic survival and selection.
- (d) Direct and indirect interspecies symbiosis in the biosphere, such as predators avoiding boom and bust in herbivores.

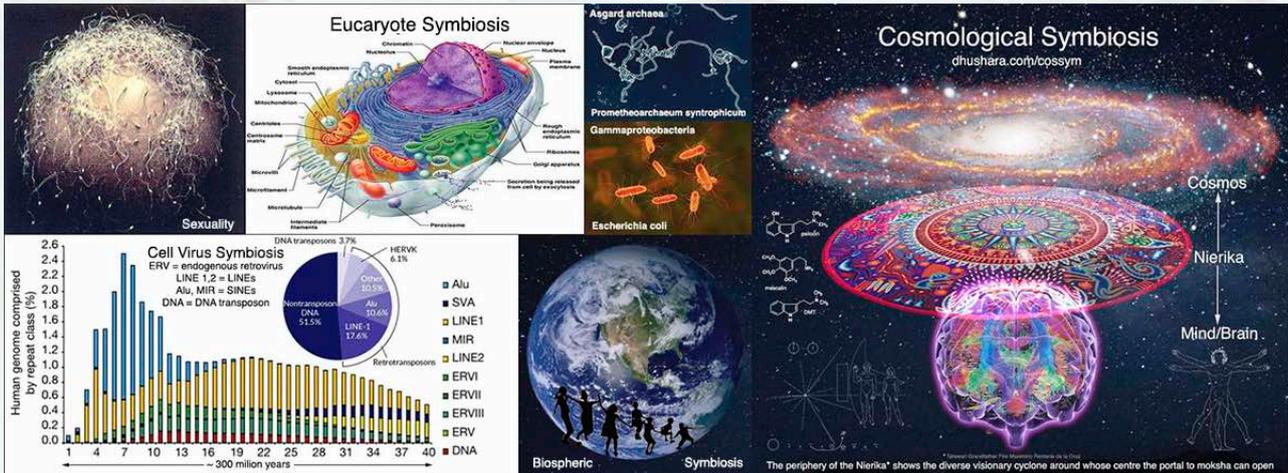

Fig 8: Multiple forms of symbiosis involve the symbiosis between Asgard archaea and proteobacteria to form the eucaryotes (top centre), sexual complementarity, where two of more strains enter into a prisoners' dilemma of sexually-antagonistic co-evolution promoted by symmetry-breaking between ovum and sperms and their differing reproductive investments (top left), Cell-virus/TE symbiosis in which 52% of the human genome consists of transposable element (TE) sequences, biospheric symbiosis in which natural and sexual selection under mutational variation leads to the survival of the fittest biospheric symbionts, whether parasite, host, predators or prey and psychic symbiosis in which plant and fungal species modify the experiential brain dynamics in humans and other species. Human TE evolutionary history, including LINES (yellow), SINES (light and dark blue), retrovirus-like LTR (long-terminal repeat) elements (green/cyan) and DNA transposons (red). This history extends back over the entire mammalian evolutionary epoch, with around 8% and 4.5% divergence respectively every 25 million years, indicating the very ancient basis of this relationship, which extends 105 million years to the eutherian radiation (International Human Genome Consortium 2001).

Organismic symbiosis is then realised in **biospheric symbiosis** of each species within the biosphere as a whole, in which natural and sexual selection is a measure of survival of the most successfully symbiotic species within the biosphere, whether parasites, prey, predators or hosts.

Ultimately, **society** and **culture** are also examples of symbiotic survival, however human emergence has been fraught with species-focused selection, leading to **egotistical consciousness**, tribal and civil warfare, as well as **sexual wars of dominance** between the male and female sexes, in which **patriarchy** has compromised the sexual prisoners' dilemma, inhibiting female reproductive choice essential for XY-based evolution and breaching human equilibrium with the biosphere, in exponentiating **devastation of the natural habitats** of the planet, **climate crisis** and **resource crisis**. The prosocial effects of psilocybe species have also been proposed to have played a role in the emergence of human culture (Rodríguez Arce & Winkelman 2021). The natural correction to this scenario comes from the complex sensitivity of conscious existence **not being the exclusive dominant possession of a single species *Homo sapiens***, but is achieved in **psychic symbiosis** between *Homo sapiens* and other biospheric species.

A critical feature of the cosmology is that it was discovered by a mathematician with a research interest in biocosmology, neurodynamics and chaotic quantum processes, as a result of an experience on **psychedelic mushrooms**, which brings us to the final stage of psychic and cosmological symbiosis.

Psychic symbiosis. The end result of this process is that biospheric evolution has led to certain species, such as several cacti, mushroom species, and a variety of plant species producing neurotransmitter analogues which act as paradoxical super-agonists, currently having the umbrella name of classic psychedelics. These send the dynamical processes evoking subjective consciousness, perceptual processes and particularly the default mode and associated networks supporting individual ego dynamics for organismic survival, in **organismic consciousness** into a deeper form of **primary consciousness**, in which these dynamics revert more closely back towards collective survival, or even deeper into a form of abstract consciousness, which the experiencer identifies with "ultimate reality", expressed by Aldous Huxley as the **mind at large**, associated with the merging of personal identity with the compassionate totality of existence. Individual consciousness is then an encapsulation of the mind at large, filtered through the coherent brain activations associated with organismic consciousness. Thus while more elementary levels of subjectivity are not perceivable to human observers, organismic and primary consciousness are, making the cosmology verifiable. Multiple papers by the Johns Hopkins team (Griffiths et al. 2006, 2007, 2011, 2018) and others, attest to a building statistical validation.

This type of psychedelic experience⁸ has deep parallels with the mystical states of **moksha**, **satori**, **epiphany**, **immanence** and **enlightenment**, spanning both Eastern and Western spiritual and religious traditions and planet-wide traditions of shamanism. In reductionistic science, where consciousness is regarded merely as an epiphenomenon, this is regarded as hallucination, or psychosis, of no external significance. In theistic traditions it is regarded as either negative possession or positive emanation of holy spirit. In the Upanishads it is accepted as the ultimate reality in the union of Brahman with the atman, or inner self, in the manifestation of cosmic consciousness.

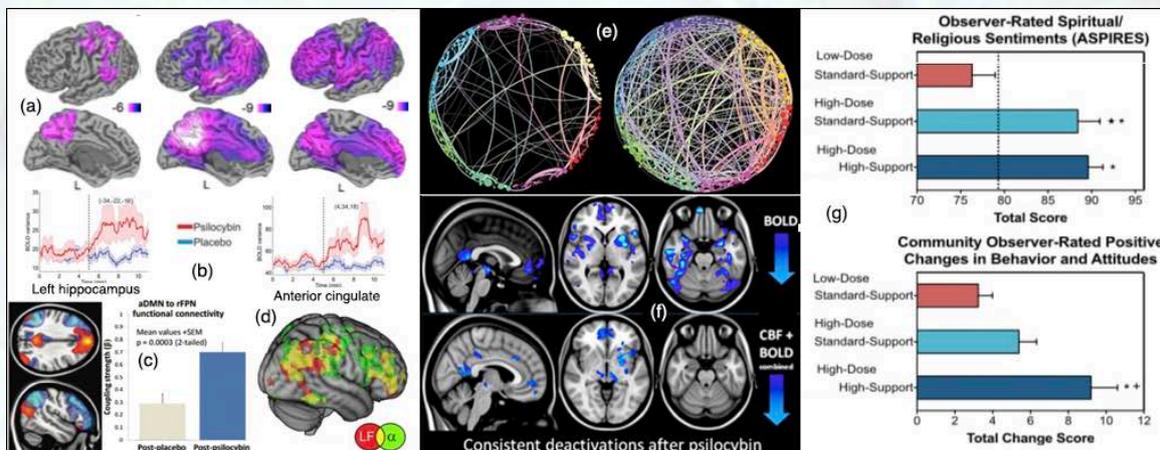

Fig 9: (a) Reductions in alpha (8-15 Hz) and delta (1-4 Hz) MEG power for psilocybin (Muthukumaraswamy et al. 2013), consistent with greater signal desynchronisation on psilocybin. (b) BOLD Variance time courses (obtained over a 1 min. sliding window) for the psilocybin and the placebo infusion (Tagliazucchi et al. 2014) showing greater variance on psilocybin. (c) Increased functional connectivity between the default mode network (DMN0 and r-fronto-parietal cortex after psilocybin (Carhart-Harris et al. 2013), consistent with the “unconstrained mind” (Lifshitz et al. 2018). (d) Decreased low frequency power (LF) and power spectrum scaling exponent α after psilocybin infusion (Tagliazucchi et al. 2014). (e) Persistence homological scaffolds for placebo (left) and psilocybin (right) showing greater inter-connective persistence on psilocybin (Petri et al). (f) Reduced BOLD activity after psilocybin in areas related to the DMN (f) A recording during the 12 minutes after intravenous administration of psilocybin 2mg (~15 mg orally), which shows reduced activity in medial frontal cortex (mPFC), posterior cingulate cortex (PCC) and other areas. (Carhart-Harris et al 2012). (g) Two indicators of beneficial spiritual and social effects of psilocybin at 6-months after the experience Griffiths et al. (2018).

Moksha is an almost unattainable objective for most people, leading to wishful reincarnation in Eastern traditions, where enlightenment is delayed to a future lifetime. Symbiotic cosmology is also the realisation of the tantric origin of Shakti-Shiva as mind and world, and of the Yin/Yang of the Tao. The key that psychedelics provide is that, among their diverse phenomena, there is a portal called the *nierika* by the Huichol, which leads to a state of deep cosmic consciousness sometimes described as the “spirit world”. It is also reflected in Yeshua’s saying:

“It is I who am the All. From me did the All come forth, and unto me did the All extend”.

The common elements of peak psychedelic experience are of a consistently mystical quality, established in recent scientific research, invoking the experiencing of “ultimate reality” and the consistently transformative effect on peoples lives suggest they do have a common aetiology, consistent with cosmic consciousness and that this process is real. This provides evidential data, in the form of veridical reports having statistical significance in the same way that objective scientific measurements do. This places **psychedelics as the subjective complement of the LHC in physics**.

Symbiotic Existential Cosmology provides a completely different solution from both a purely **materialistic cosmology**, in which the universe is described as a causal process, in which consciousness life is passive, meaningless and irrelevant; and a **theistic cosmology** in which life on Earth is a disposable moral trial created by a non-evidential external third party called God for a future life of eternal bliss or hellish punishment. Neither do Eastern cosmologies, dependent on notions of moral karma and endless reincarnation in a world of illusion, respect the material, genetic and ecological manifestations of natural embodied life. All these traditional cosmologies devalue the role of the evolving diversity of perennial conscious life in the universe, leaving us with a wasteland of apocalypse and Armageddon. Symbiotic cosmology invokes immortal paradise, so long as Earth shall live and beyond Earth to the stars,

⁸ I am not suggesting that everyone should take these agents to achieve such states, but just that they need to be respected as having these potentials for existential insight by society as a whole. Neither am I recommending that people take them without expert guidance, at least at the outset. Neither am I suggesting they be taken by minors, until the age of full adult legal consent.

if we can learn to survive in evolutionary time. It is the real cosmology of the living universe while religious and materialistic cosmologies are tragic fallacies of the imagination.

Cosmological symbiosis: In symbiotic cosmology the purpose of the cosmological process is so that the universe can reach edge of chaos climax and manifest, experience and know itself, through the structural cosmological pathway leading to fractal complexity, life and consciousness, in which the biota, and *Homo sapiens* as a climax species, comes to experience forms of awareness, realising and manifesting cosmological self-consciousness.

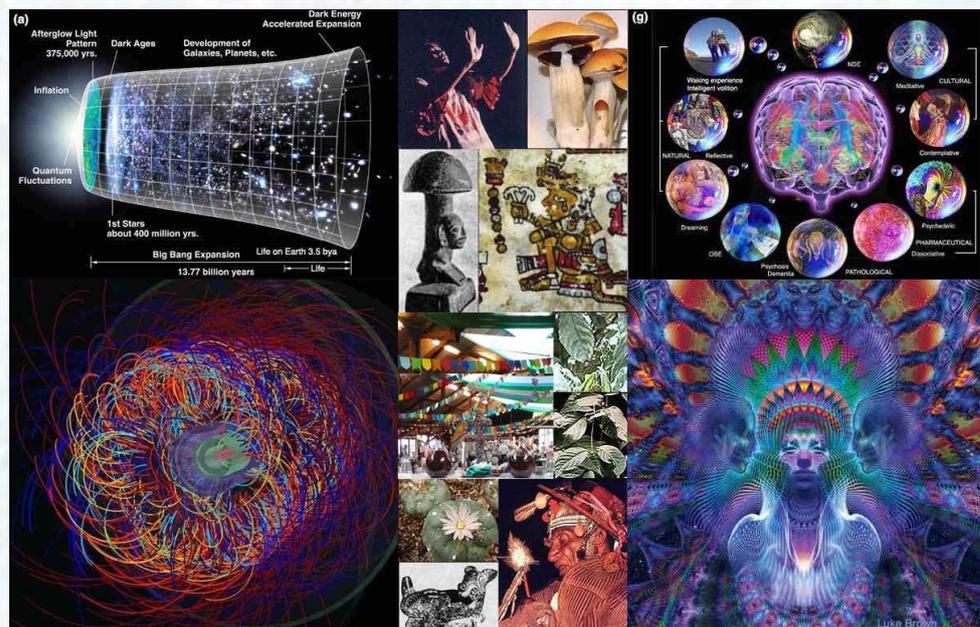

This is a scientific cosmology, which imparts an even greater responsibility and urgency on humanity than religious cosmologies – to act as conscious guardians of the biosphere, to cherish and protect the living universe as sentient cosmological manifestations of it. This also has profound spiritually fulfilling implications, in which conscious beings become both immanent and transcendent guardians of the diversity of conscious life – i.e. becoming as Gods in terms of Genesis, regaining the mythical Tree of Life hidden since the foundation of the world:

Behold, the man is become as one of us, to know good and evil: and now, lest he put forth his hand, and take also of the tree of life, and eat, and live for ever: Therefore the LORD God sent him forth from the garden of Eden. (Genesis 3:22).

This in turn imparts to us a “galvanising” responsibility, as cosmological manifestations of sentience to use our lives fruitfully to preserve and ensure the passage of the generations of conscious life in overflowing abundance. To protect the planet from mass extinctions, while experiencing the full deep abyss of conscious awareness, so that the evolving manifestation of consciousness is able to unfold. We are the agents of transformation and the decisions we make will shape the universe around us, making a paradisiacal, purgatorial or hellish history as we speak. Our lives are then truly connected to the immortal web, through intimate conscious identification with the flow of life as a whole, solving the dilemma of organismic mortality in the physical world. This again is why psychedelics are therapeutic for people in depression and terminal illness (Carhart-Harris R et al. 2016, 2017, Griffiths R. et al. 2016) and why they are also conducive to increased nature-relatedness (Lyons & Carhart-Harris 2018).

Symbiosis and Human Survival: Put very simply, a biosphere cannot survive in evolutionary time if there is a dominant species whose emergence remains tribal in basis. But that is the natural condition for any emerging dominant species like *Homo sapiens*. So the fully evolved expression is not species dominance, but biospheric symbiosis. So called classic psychedelics provide a core pathway to achieve this, because their affects on ego, particularly in a state of meditative withdrawal, or trance fixation, can undergo a transition to the ‘abstract’ state of consciousness that Aldous Huxley denoted “the mind at large”. Cosmological symbiosis is consistent with a fully technological civilisation, in which science and vision can both flourish, because it engenders a symbiotic civilisation, which can survive on cosmological time scales. A dominant species-driven technological civilisation is not sustainable because it is self-destructive through biospheric exploitation and collapse and sheer short-term instability. Religious cultures are likewise prone to self-destruct through lethal theistic misadventure.

Fig 10: Physical cosmology and the cosmology of mental states illustrated by lead ion collisions in the LHC and “Curandero” Luke Brown’s illustration of psychedelic experience and natural psychedelics in traditional use.

Symbiotic Existential Cosmology – Discovery and Philosophy

Contents:

The Existential Condition and the Physical Universe

Turning Copernicus Inside Out

Discovering Life, the Universe and Everything

The Central Enigma: What IS the Conscious Mind?

Fig 11: Cosmology is a paradoxical complement of two manifestations – quantum reality and subjective consciousness. The classical world around us arises from consciousness collapsing the overlapping parallel worlds of quantum reality, to evoke the historical process via our intentional will. We are thus personally responsible for the fate of existence.

The Existential Condition and the Physical Universe

The human existential condition consists of a complementary paradox. To survive in the world at large, we have to accept the external reality of the physical universe, that we bleed if cut and may become unconscious or die if hit on the head, but we gain our entire knowledge of the very existence of the physical universe through our conscious experiences, which are entirely subjective and are complemented by other experiences in dreams and visions which also sometimes have the genuine reality value we describe as veridical⁹. The universe is thus in a fundamental sense a description of our consensual subjective experiences of it, experienced from birth to death, entirely and only through the relentless unfolding spectre of subjective conscious existence. Thus although we scientifically associate subjective consciousness with integrated dynamical brain states, the physical universe manifests through conscious experience. Materialists attempt to defer this by saying that this is just the way it appears to a biological organism imprisoned in their own internal model of reality, which will seem like this, but is only a feature of their subjectively confined point of view. This is incorrect because it then leads to the hard problem of consciousness and the failure to recognise volition.

We are thus subjectively conscious beings possessing volitional will over a physical universe we know only through our conscious experience of it, and our creation myths and scientific descriptions attempt to make sense of our predicament. The universe in turn becomes manifest, only through its conscious sentient beings, the biota, so the meaning of existence is created through our journey of discovery as conscious agents transforming the universe by our insights and actions. We thus in turn inherit a foundational responsibility for our actions cosmologically.

When we confine our discourse to dealing with the properties of external physical reality, we end up with what has become the exceedingly complex scientific description of the natural universe. This appears on macroscopic scales to be a giant causal mechanism made of atoms and molecules, leading to our complex brains and the way brain processing leads to the decisions we make in the physical world. This in turn leads to the notion that our subjective conscious minds are just an internal model of reality created by the computational brain to sum up the outstanding

⁹ *Veridical* – truthful, coinciding with reality. Etym. "speaking truth" Latin *veridicus* "truth-telling, truthful," from *verum* "truth," neuter of *verus* "true" + *dic-*, stem of *dicere* "to speak".

features of the world around us and that our personal sense of volition and subjective agency – the experienced ability to make decisions affecting the world around us – is a delusion, because it is the causal processes in our brains that did this, not our conscious volition.

The trouble with this point of view is the hard problem of consciousness – the fact that there is no conceivable way any physically objective brain process or a set of easier functional problems about integrative properties of brain function can explain something as intrinsically subjective as conscious experience. As Jerry Fodor said: “Nobody has the slightest idea how anything material could be conscious. Nobody even knows what it would be like to have the slightest idea about how anything material could be conscious.” This is the dilemma that the easy problems of consciousness cannot be contrived into an objective structural description that solves the hard problem. At best, we end up with pure informational models identifying human consciousness with integrated biological forms of artificial computational intelligence.

Fig 12: Constructing our description of reality based on the external physical world since Copernicus carries incredible explanatory power because nature is complex and provides a detailed physical and biological description, but in terms of subjective experience and conscious existence, relying exclusively on the external objective details paints us into a corner where we cannot solve the hard problem of consciousness, because the external objective description is categorically incapable of modelling or manifesting intrinsic subjectivity.

There is also a fatal flaw in the dependence of physical neuroscience on classical notions of casual closure as a mechanism. The discovery of quantum reality at the beginning of the 20th century has shown us that the universe is not causally closed and that quantum uncertainty and its spooky features of quantum entanglement can intervene throughout. The reason for the incredible technological success of science is thus not the assumption of macroscopic causality at all, but the fact that the quantum particles come in two kinds. The integral spin particles, like photons, called bosons, can all cohere together, as in a laser and thus make forces and radiation, but the half-integer spin particles called fermions, like protons and electrons, which can only congregate in pairs of complementary spin, form matter, inducing a universal fractal complexity, via the non-linearity of the electromagnetic force. Given the quantum universe and the fact that brain processes are highly uncertain, given changing contexts and unstable tipping points at the edge of chaos, objective science has no real basis to claim the brain is causally closed and thus falsely conclude that we therefore have no agency to apply our subjective and consciousness to affect the physical world around us.

So what if we reverse the cosmological argument and begin with the foundations of conscious existence, in the form of subjective consciousness affecting the physical world around us through our veridical experience of our conscious intent – our volitional will affecting the world around us, as we witness in everything we do behaviourally in the world? By veridical, I mean we are telling the actual truth about our conscious experience and our consciously experienced volitional intent to make decisions and execute physical actions. I use the term veridical because when we do anything physical we have an unswerving conscious impression that we have genuinely intended something and executed a physical action whose consequences we are responsible for as active agents. We are consciously aware that we are intending a physical action we are undertaking. This is the veridical perception of our intention that materialistic neuroscience is denying when the conscious mind is treated as an epiphenomenon having no physical affect. Organismic perception of the real world is described as “veridical perception”¹⁰, because it is designed to give an accurate portrayal of the world, realer than the incoming sensory data, in our case in binocular 3-D, with size preservation, conducive to an accurate detailed view, ensuring evolutionary survival in the wild. The key aspect of

¹⁰ Natural selection has shaped our perceptions to be, in the typical case, accurate depictions of reality, especially of those aspects of reality that are critical for our survival. “People could not orient themselves to their environments, unless the environmental information reaching them through the various sense organs offered a perception of space that corresponds to their physical “reality.” Such perception is called veridical perception – the direct perception of stimuli as they exist. Veridical perception also causes a person to experience changing stimuli as if they were stable: even though the sensory image of an approaching tiger grows larger, for example, one tends to perceive that the animal’s size remains unchanged. One perceives objects in the environment as having relatively constant characteristics despite considerable variations in stimulus conditions” (Britannica, APA).

consciousness us that we are aware that we are aware. Materialistic neuroscience denies that our perception of our volition is veridical, contradicting the fact that this is as necessary to survival as our veridical perception of the world.

Existential cosmology has the opposite effect from reducing consciousness to mere information, by contrast imbuing at least some forms of matter, such as brains, with an extra complementary subjective aspect that we witness and execute as conscious experience and volitional intent. Although this is counter-intuitive to pure materialism, it is a vastly more plausible and realistic approach than denying human agency by a fatal *reductio ad absurdum* of existence. Rather than ghosting us as walking AI machines lacking free will, it introduces profoundly exciting new properties into the physical universe, explaining conscious existence in the material realm!

Enter existential cosmology, which starts from the conscious level as we all do, and develops our cosmological world view as a transaction between subjectively conscious live human beings, to discover and deduce the cosmological conditions of the world around us as living conscious agents affecting the natural world. This leads to a very different conclusion from materialistic physical cosmology, although it is entirely consistent with both quantum cosmology and empirical neuroscience – while materialism denies conscious volition, veridical experience implies matter has psyche.

|  | <p>Subjective Veridical Affirmation by Mutual Agreement</p> <p>Two conscious agents agree on a true account confirmed by empirical experience e.g. that they each possess volitional efficacy of decision-making.</p> |
|  | <p>Belief through Prescriptive Faith</p> <p>Things held to be true as a matter of religious doctrine or revealed command. Agents are led to conviction of the truth of an alleged fact without personal knowledge, or evidence.</p> |

Fig 13: **A: Objective physical verification** proceeds by two agents or groups recording consistent outcomes from independent empirical experiments or one group verifying the theoretical prediction of another. **B: Subjective conscious veridical affirmation:** Two conscious agents confirm a common truth through affirmation by empirical experience. e.g. in sworn testimony, political agreements and entrusted relationships. **C: Belief through prescriptive faith** in religious doctrine involves conviction of a doctrinal truth without actual knowledge or experiential or objective evidence of the proposal or phenomenon. **Symbiotic existential cosmology** utilises A objectively and B subjectively. It also encompasses visionary experiences consistent with C but only if they satisfy B, alleviating the explanatory gap of “soul” being equated with belief (Freeman 2008).

Existential cosmology is thus verified as a conscious transaction of volitional agency between live human beings, in a veridical affirmation: As you read this

passage, you are becoming consciously aware that I have, as a live human being, **consciously and intentionally committed this communication to physical electronic form**, thus affirming that my **subjective conscious volition has had a physical effect on the universe**.

Normally this would be a mutual affirmation between two conscious agents in one another’s presence of their veridical efficacy over the world. It is almost absurd to have to make this claim explicitly because it is assumed in all our interactions! Some less materialistic people may wonder why this needs to be stated, but the scientific era has brought it into question and it is pivotal to establishing the conscious volitional paradigm.

By consciously comprehending the truth of your self-evident affirmation of my volition above on receipt of this, you are empirically, by your own experience confirming the core thesis of existential cosmology, which asserts that subjective conscious volition is physically realisable. This also implies that at least some physical matter, including the brain, has a complementary subjective aspect, but the brain is ordinary matter subject to the four core quantum forces, so this means the physical universe has a complementary subjective aspect, from which the evolutionary implications of Darwinian panpsychism and Symbiotic cosmology as a whole follow. Existential cosmology is thus a subjectively verifiable discovery, in the creative commons, which can be affirmed empirically by experience¹¹.

By veridically affirming the author’s volitional agency and noting this fact physically, you are also affirming your own volitional agency over the physical world. Therefore, on receipt of this communication, we each become consciously responsible and fully accountable for the discovery’s consequences, as conscious human beings whose volition affects

¹¹ *empirical* based on, concerned with, or verifiable by observation or **experience** rather than theory or pure logic.

Etym. Greek *empeirikos*, from *empeiria* ‘experience’. Observational empiricism is appropriate for verifiable physical investigation and experiential empiricism for veridical conscious affirmation.

the world. This is not a moral responsibility but a responsibility, as a conscious agent, to the veridical truth of what you have experienced and its implications about your own volition upon the world as a conscious human being.

No unverifiable claim that awareness of volition is correlation, not causation, and my physical brain wrote this passage, or developed the entire cosmology on its own, without my conscious volition affecting the physical universe, and at the same time fooled my conscious experience into believing I had done it consciously, as a passive epiphenomenon will suffice as an avoidance of your duty of care as a conscious human being, to affirm its experienced veridical truth.

You are free to transmit this work to others in intact form, to critique it, or to communicate a critical flaw to the author, but you cannot escape the duty of care to be honest about the veridical truth of the transaction and its thesis and to communicate it honestly to others. In a sense this is not asking anything more from the reader than the simple cognisance that I have subjectively applied my conscious volitional will to commit this consciously discovered thesis to physical form, as all live consciously active human beings do every day, by their actions. However the responsibilities are acute and pivotal to the capacity of the cosmology to ensure human survival over evolutionary time scales.

The process of mutual affirmation also has significant social implications because it leads to a social paradigm where decisions are made by autonomous mutual agreement, rather than hierarchical structures and institutions. It leads to new social models of fractal ecosystemic democracy, or lateral democracies by mutual consent such as holacracy and sociocracy.

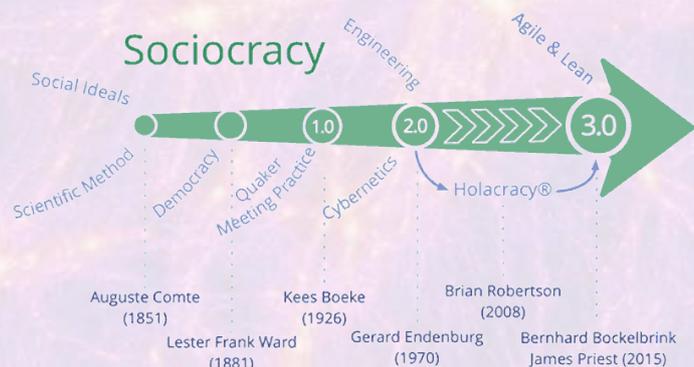

Fig 14: The social evolution of sociocracy models of society.

Symbiotic existential cosmology, as explained in the scientific overview, consists of three interlocking realities:

- (1) **Biogenic:** Life exists cosmologically as a fractal consequence of the symmetry-breaking of the forces of nature reaching interactive climax.
- (2) **Panpsychic:** Subjectively conscious volitional will has efficacy¹² over the physical universe.
- (3) **Symbiotic:** The planetary biosphere survives and evolves through ecosystemic symbiosis, upon which human survival is dependent. Biospheric symbiosis is thus essential for human survival.

The cosmology arose as a result of an experience on psychedelic mushrooms, but the significance of the cosmology itself extends far beyond entheogenic visions. It is in fact the actual cosmology of the universe in which we consciously exist. It is fully consistent with both quantum cosmology and with empirical neuroscience, and it has truly extraordinary implications that are in no way dependent on psychedelics themselves:

1. It **restores human conscious volitional agency**, currently denied by materialistic neuroscience and morally bound by religious belief, and returns ethical and legal responsibility for our actions back to the human species, and does it in the cosmological context, revealing the key role of life in the universe, as shown at Σ in fig 15, thus imbuing humanity with a clear responsibility to protect and unfold conscious life over evolutionary time scales.
2. It **has the direct capacity to save the biosphere and humanity from mass extinction**. Its symbiotic implications form a central remedy to avoid a climate and biodiversity crisis which could cause a mass extinction of the diversity of life, setting humanity back 50 million years and very likely causing the extinction of Homo sapiens, due to a failure to live symbiotically with the biosphere upon which we co-depend for our survival.
3. It **realises the existential quest of human meaning and purpose in the universe**, as a cosmological climax phenomenon, enabling the physical universe to manifest and know itself, while giving each and every one of us the capacity to experience states of cosmological symbiosis in reunion with the conscious universe as a whole.
4. It **transcends both materialistic and theistic world views**:
 - (a) It **transcends scientific cosmology** because it **completes the scientific description of nature** by fully incorporating **subjective consciousness** and the **efficacy of volitional will to affect the physical universe**.

¹² efficacy – the ability to produce a desired or intended result.

(b) It **transcends religious cosmology** by **transferring cosmological agency** directly back to **humanity and natural life**, verified by **conscious affirmation of our volitional agency**, rather than dependence on supplicant beliefs.

Symbiotic existential cosmology can be empirically verified in **five principal ways**:

1. The key role of life in the universe is incontrovertibly manifest in the biosphere as a climax edge-of-chaos dynamical system resulting from the four non-linear quantum forces of nature, mid way through the universe in space-time.
2. Existential cosmology as an interaction between subjective consciousness and physical reality, is verified through affirmation by empirical experience between conscious human volitional agents, in the same manner that legal transactions, such as sworn evidence, fiduciary duties of care and terms of trust are veridically affirmed. This is necessary for applying Occam's razor to eliminate materialistic cosmologies failing the volitional efficacy test fundamental to human decision-making autonomy and personal responsibility for our actions upon the world.
3. The extent of subjective volitional consciousness across the evolutionary tree can be verified through empirical observation of volitional purposiveness in eucaryotes.
4. Organismic and biospheric symbiosis are irrevocably manifest properties of all eucaryote species and the biosphere as a whole as a climax system. Psychic symbiosis has become a cultural practice of diverse human societies.
5. Cosmological symbiosis is verified by statistical evaluation of quantum change experiences of "ultimate reality", in psychedelic and meditational states, as demonstrated in studies by the Johns Hopkins team and others.

Turning Copernicus Inside Out

The current human weltanschauung, since an exilic writer wrote the sabbatical Genesis 1, started out as a flat Earth with beaten domes (firmaments) in which the plants were created before the sun and moon. Until Copernicus, this was an anthropocentric view of God's creation. Copernicus then flipped it to the heliocentric objective universe, causing our thinking to turn inside out and become obsessed with describing everything, including our most subjective realities, in objective mechanical terms, until quantum reality intervened.

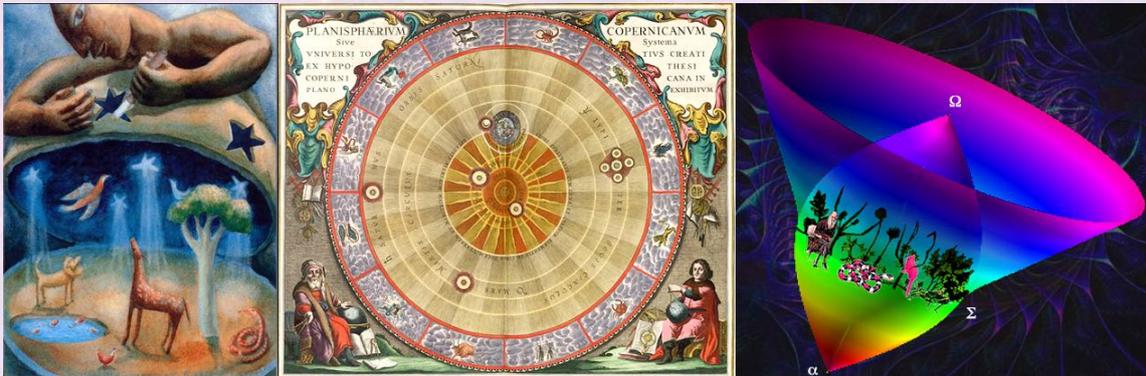

Fig 15: 'Elhoistic Flat Earth Sabbatical Eden and Copernican Classical Heliocentrism, in Symbiotic Existential Cosmology become Conscious Paradise on the Cosmic Equator Σ in Space-time, between the big-bang origin α and the final crunch, or heat death Ω . This way, instead of running down into the Kali Yuga or the Buddhist Samvartakalpa or Eon of dissolution, or being static as in the Monotheist creation, which is then discarded in the End of Days, the universe explodes with evolving living diversity in Paradise on the Cosmic Equator in Space-Time! It's more than the noosphere, it's the biocosmos revealed – **Voilà!**

Symbiotic Existential Cosmology doubly inverts the Copernican principle: That humanity does not have a privileged view of the universe. SEC does a double flip on this as well. Firstly the universe is NOT heliocentric. The structural interaction pathway goes through two cycles. Firstly younger hotter stars generate the chemical elements from hydrogen and helium and supernova them into galactic gas clouds which are then swept up into smaller longer lived sun-like stars with solar accretion discs, where a second long period of biogenesis and then biological evolution ensues. Thus we end up at picture three on the right, paradise on the cosmic equator in space time. We are not 4.5 billion years old but our stuff is much older, say 10 billion out of the universe's 13 billion year lifetime, so the cosmic equator is now about half way through in space-time, with a good 5 billion to go before we red giant. But there is the second flip. Due to the eucaryote endosymbiosis between archaea and bacteria, life became complex conscious organismic life and the cosmic equator has become conscious flipping the privileged view of the universe right back to consciousness itself, so we are nearly back to square one, the Garden of Eden in Genesis 2 and 3, except that we are dire straights from human misadventure! That's precisely what the Brahmanic quantum change experience I had on mushrooms was saying! What a hell of a fix! So we really do need to act to avoid the extinction!

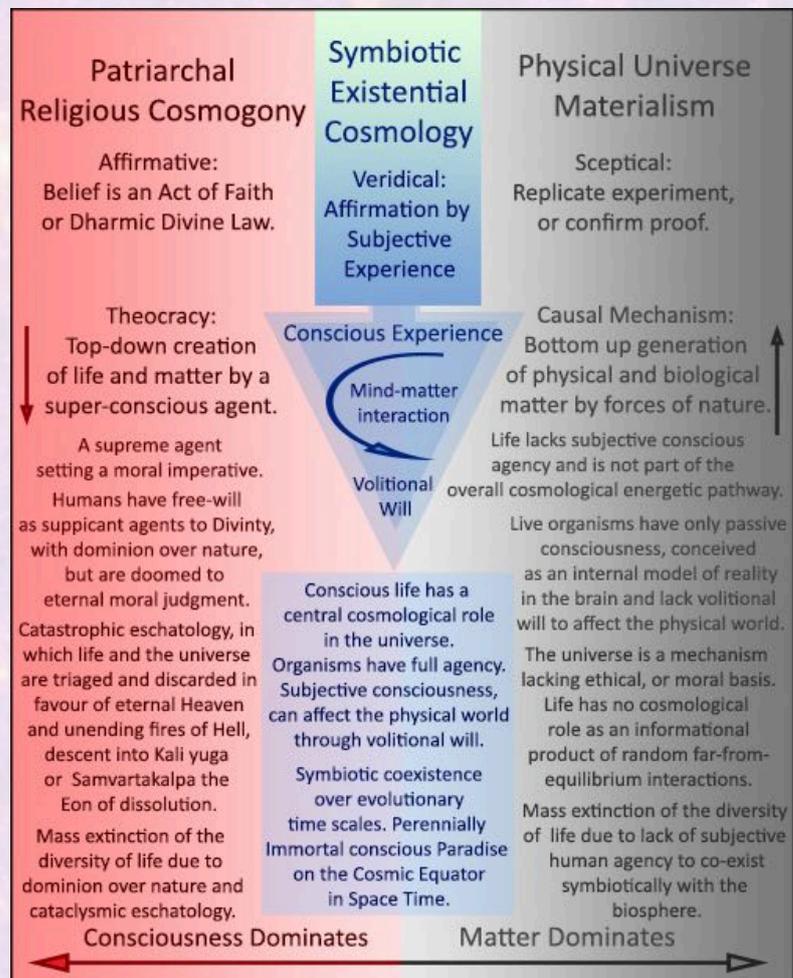

This in turn resulted in the rise of classical materialism defined by Newton’s laws of motion, after watching the apple fall under gravity, despite Newton himself being a devout Arian Christian who used scripture to predict the apocalypse in Parousia arriving in a “second coming” in 2060 (Snobelen 2003):

This most beautiful system of the sun, planets, and comets, could only proceed from the counsel and dominion of an intelligent Being. ... This Being governs all things, not as the soul of the world, but as Lord over all; and on account of his dominion he is wont to be called "Lord God" παντοκράτωρ [pantokratōr], or "Universal Ruler". ... The Supreme God is a Being eternal, infinite, [and] absolutely perfect (Issac Newton).

Nevertheless the classically causal Newtonian world view, and Pierre Simon Laplace’s view of mathematical determinism “that if the current state of the world were known with precision, it could be computed for any time in the future or the past”, came to define the universe as a classical mechanism in the ensuing waves of scientific discovery in classical physics, chemistry and molecular biology, climaxing with the decoding of the human genome. By contrast with Newton, it is said that when Napoleon asked Laplace, who was called “the weathercock” for his political survival skills, why he had never even mentioned its Creator in his work, he answered bluntly, *Je n'avais pas besoin de cette hypothèse-là* – “I had no need of that hypothesis”.

This classical causal view has extended to a view in neuroscience that our subjective conscious experiences, which are the sole avenue we have to experience the physical universe are simply an internal model of reality generated by the brain, viewed as a causally closed physical mechanism preventing volitional will having any efficacy. This view still pertains, despite the discovery of quantum reality at the beginning of the 20th century, in which causality is overshadowed by quantum uncertainty and its effects, on the basis that these do not apply to a warm wet brain. However, this claim is empirically unprovable and is likely to remain so. The end result is that the central arena of our subjective experience and our volitional agency over the physical world have been treated by neuroscience as null and void, leaving neuroscience with no way to elucidate how the objective brain can generate something intrinsically subjective by any causal mechanism conceivable – otherwise called “the hard problem of consciousness”. This leaves our conscious existence in an orphan status and our sense of agency and living meaning and purpose in the universe non-existent.

Fig 16. Symbiotic Existential Cosmology stands centrally between two degenerate descriptions of nature, fully confirming the autonomy of human conscious volitional will to affect the universe and for human beings to have full responsibility over our physical actions. Patriarchal religious cosmogony, left invokes free-will but binds it to eternal punishment by a super-conscious agent. Physical materialism, right lacks any conscious human agency, regarding subjective conscious experience as simply an internal model of reality generated by the physical brain as a passive epiphenomenon, lacking any capacity of conscious volitional will to affect the physical universe. Physical Materialism and Patriarchal theism are both fated to lead to a mass extinction of the diversity of life and eventual human extinction, due to apocalyptic destruction in favour of an imagined Heaven/Hell bifurcation on the religious side and, on the materialist side, the complete failure to accept conscious life has a cosmological role in the universe which humans, as conscious volitional agents affecting the world have become responsible for, by our impact on Earth’s climate, habitats and biodiversity. Only by affirming symbiotic existential cosmology does the human species have a consistent cosmological basis and a good chance of long-term survival in the biosphere over evolutionary time scales.

In figure 16, symbiotic existential cosmology occupies the central place between theistic cosmology, dominated by a superconscious agent creating the universe, and physical materialism in which the universe is described as a giant causal mechanism, although it has been more recently been found to be also subject to quantum uncertainty on the scale of wave-particles and their ensuing “spooky” properties in quantum entanglement. Both the theistic and pure materialistic descriptions are degenerate in complementary ways.

Symbiotic existential cosmology corrects this fatal flaw in the scientific model elegantly, by starting from our conscious ability to apply volitional will to affect the universe and making a minimal augmentation of quantum cosmology to include the subjective aspect. This immediately inverts the Copernican principle, because it deduces that subjective consciousness in the advanced biota and hence humanity is the climax phenomenon of the biogenic interactive pathway, giving us not only a privileged view but the central experiential view of the universe, as a manifestation of a consciously purposive cosmos. Copernicus is turned inside out because the world outside regains its complement, the mind-at-large inside, through which the universe can perceive and manifest itself.

Symbiotic cosmology is absolutely pivotal to the human species regaining volitional autonomy and the ability to take responsibility of ensuring our species learns to respect our symbiotic relationship with the biosphere essential for our long-term survival. Without this, the prospect of a mass extinction event setting us back 50 million years and possibly causing our own extinction is almost inevitable.

Pure physically materialistic cosmology leads to a meaningless universe, in which life is an ineffectual by product, the brain is a biochemical machine, consciousness is a functionless epiphenomenon, volitional will is a delusion, and society is reduced to abstract information systems, with no ethical reason to preserve conscious life, or the diversity of natural life, predisposing to biospheric collapse, ultimately subject to AI catastrophe due to a failure to distinguish conscious life from mere information.

Fig 17: Physical materialists who, by their expressed position, are religiously unaffiliated, count only a diminishing 16%, diminishing to 12.5% of the world population by 2060 (Pew Research 2017). This means that unproven assumptions that life lacks conscious volition and is just a causal computational mechanism in the brain have no credible chance of success in advancing the scientific description of nature to the human population at large in the coming century.

Patriarchal theistic cosmology by contrast, discards the late planet Earth in envy of Heaven and fear of Hell, in an apocalyptic tumult of life’s destruction, and of the universe itself, as God’s disposable creation, or in the Eastern mind-sky view a degenerating Kali¹³ yuga again leading to human and natural extinction. Figure 17 shows that, despite the incredible nature

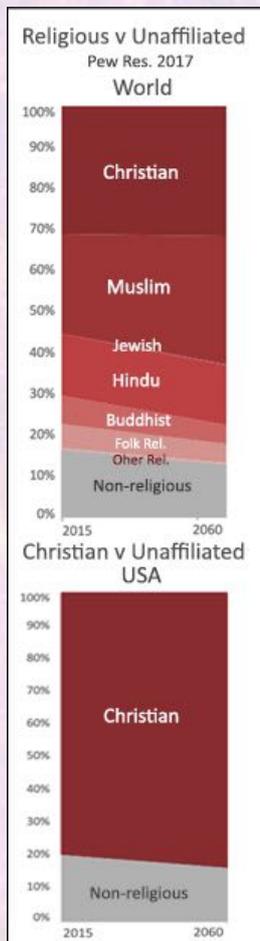

of theistic cosmology in the natural universe, far more people adhere to a religious view than are unaffiliated, partly because it does provide a realistic although moralistic view of human consciousness and free-will. This means that the scientific world view and particularly materialistic neuroscience, in the absence of an acceptance of the central place of conscious existence and volitional will has no hope of gaining widespread acceptance this century.

Symbiotic existential cosmology, is an entirely novel cosmic perspective on reality that transcends both these corrupt descriptions and thus seeks to remedy our existential angst¹⁴. The unfolding diversity of conscious life is central to the cosmic process, also realising the visionary core of spiritual traditions through first-person transcendent consciousness, superseding both naive belief in a creator deity, for which no conceivable evidence actually exists and a physical universe lacking meaning, purpose, and awareness of its own existence.

“The world is a construction of our sensations, perceptions, memories. It is convenient to regard it as existing objectively on its own. But it certainly does not become manifest by its mere existence” ... “The reason why our sentient, percipient and thinking ego is met nowhere within our scientific world picture can easily be indicated in seven words: Because it is itself that world picture” (Erwin Schrödinger 1944).

¹³ This use of Kali is as an eschatological demon, distinct from the Goddess Kālī, who like Brahman, is conceived of as a form of “ultimate reality”.

¹⁴ **angst** – a feeling of deep anxiety or dread, typically an unfocused one about the human condition or the state of the world in general.

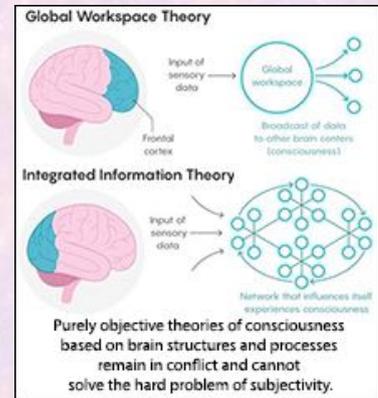

Foundations and Diversity of Existential Cosmologies

Existential cosmology is derived from the fundamental paradox that although we know we are dependent upon the physical universe for our biological survival, we access reality at large entirely through empirical experience of our subjective sensory perceptions of it. This means that, to fully describe the natural cosmos, we have to do so through validating the role of subjective consciousness as a cosmological principle. As noted in fig 16, Symbiotic Existential Cosmology stands mid-way between two theoretical extremes.

(a) Universe Dominant: Physical Materialism

Such cosmologies fail because no objective account, based on the form, or complexity, of brain structures and processes can of themselves manifest subjectivity, so can't solve the hard problem of consciousness extended to volition. They result in a purely mechanistic causal description complemented by probability measures in quantum phenomena, in which there is no explanation for subjective consciousness except as a higher level internal model of "reality" constructed by the physical brain, unable to distinguish living conscious sentient organisms from mechanical processes such as AI, as well as lacking any ethical or moral direction, except as reinforcement, to reduce intra-social competition to enhance inter-social dominance. A living and a dead reality have no real distinction because conscious organisms are just physical structures.

(b) Mind Dominant: Monotheistic, Vedantic and Buddhist Pure Mind Theories

These fail for complementary reasons, because all "aggregates" of purely subjective phenomena remain subjective. Cosmic consciousness creating the physical universe is inconsistent with the clearly emergent properties of the known universe, in which conscious biota come late in the process: (1) The emergence of the universe from the cosmic origin is a multi-stage processes in a symmetry-breaking, giving rise to the forces of nature, the evolution galaxies stars and planets and the genesis and the evolution of life reaching climax in conscious organisms as a late comer. (2) From this viewpoint, full consciousness is emergent in higher organisms, meaning that for any form of cosmological subjectivity to be consistent, it has to be primally vestigial at the cosmic origin. (3) The evolutionary sequence of events, right back to the inflationary origin, is well documented, so any creation by a cosmic mind or God falls right back into the pre-inflationary phase and the Planck time, which is unobservable due to being now expanded over space-like intervals.

The idea of a fully developed cosmic consciousness generating the objective physical universe by "aggregation" from a conscious field ([Chopra](#)) subjective super-mind ([Aurobindo](#)), or a supernatural deity creating a flawed material universe by proclamation ([Genesis 1:3](#)), in each of which, the free-will to defect against divine order then dooms the future, is unsustainable. Both share an origin in an omniscient, omnipotent deity, via Indra and proto-Aryan cosmology, also emergent in both Judaism and Zoroastrianism. It is a tragic flaw of the transition from mystical insight to patriarchal doctrine. In Monotheism this leads to creationism in the guise of "intelligent design".

Such consciousness-dominant cosmologies share **three fatal features**:

- (1) **Counterfactual Contradiction.** The category error of pure physicalism that results in the hard problem of consciousness extended to volition applies in converse too. If no combination of objective entities can, as a result of this, become subjective, neither can any "aggregate" of pure subjective consciousness become objective physical reality.
- (2) **Turtles all the way down!** The entire notion of the cosmic mind or a super-natural deity making physical matter is a mystification because it leads to regress – replacing something we are trying to explain by something we cannot explain, potentially ad infinitum. The physical universe becomes a flawed appendage of a perfect deity or mind, which has itself no natural explanation, further confounding the cosmology rather than unveiling it, undermining our conscious sentient ability to transform the universe as living creative agents and our personal responsibility for our intentional actions.
- (3) **Moral Unsustainability.** The universe becomes a moral causality that has no cosmological meaning in nature, whose diversity thrives on both cooperation and defection. The cosmology is degenerate and unsustainable, running down hill to the Eschaton, Frashokereti, Kali-Yuga or Samvartakalpa.

A key aim of religious cosmologies is the supreme rule of a “divine” order, which runs into conflict with cosmological principles of the diversity of life thriving through existing at the edge of chaos, where the chaotic phase frees nature from the oppressive rule of order becoming locked into fatal attractors. It remains to be established that the notion of religious “good” being associated with “divine” order, is a feasible, or desirable, cosmological outcome.

The Visionary Numinous and Spirituality

History shows religious traditions take their origin from visionary, shamanic and mystical experiences shared by emergent human culture, for the very reason that the subjective view of reality is primary and universal and the physical world view is derived from the primally subjective world view. Thus the primitive visionary state has evolved through shamanic and meditative practices to doctrinal religions, which serve completely separate purposes of enabling larger urban societies by imposing moral imperatives and exerting patriarchal control over female reproductive choice, through punishment, militarism and social conservatism.

In this process, absolute notions such as eternal life are asserted without any real understanding of the consequences, such as how can eternal life evolve, change and be actually alive in any real sense, and the notions of eternal individual souls which are etherial “divine” versions of our personae, which again have manifest problems of the historical accumulation of an unbounded number of coexistent beings throughout history, all solved by mythopoetic and magical means. By contrast quantum reality occurs within space-time, while relativity occurs in various space-time manifolds responding to gravity, which can be viewed eternally, as illustrated in fig 15c. Out of religious belief has emerged the notion of spirituality, a softer form of affirmative belief than doctrinal religion, whose reality status remains apocryphal, based on the same or similar notions, such as a divine individual soul and eternal life.

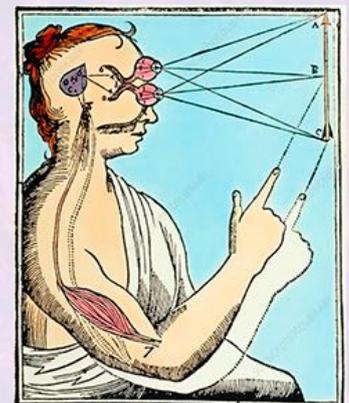

(c) Dual-aspect, Neutral Monism and Mind-Brain Identity Theories

These attempt to bridge the subject-object explanatory gap and have the common feature of trying to explain subjectivity as a complementary perspective on what is still conceived as a closed physical causal process executed by the brain, which, because of its system architecture and dynamics represents a self-organising form of physical agency for which the subjective perspective is the “inner” view of these same physical processes (Vimal 2021). Hence these tend to be passive epiphenomenal accounts, in which the subjective aspect is the systems view of a causal physical process. Bijective duality prohibits interaction between subjective and objective aspects, so there is no explanation of subjective intentionality, or will, i.e. no subjective conscious volition over the physical brain or the universe through intentional behaviour, but it can invoke panpsychism and the combinations problem. However some forms of neutral monism (Stubenberg 2018) assert that mental and physical are aspects of a common underlying reality (Atmanspacher 2018). Spinoza claimed this to be God, which he identified as “the only real substance” (Vacariu 2015).

(d) Interactive Asymmetric Complementarity

A different kind of cosmology arises from accepting the fundamentally asymmetric relationship between a subdividable analysable physical universe and a holistic integrated stream of subjective experience and allowing them to mutually interact. Descartes’ use of the pineal gland as the site of the Cartesian theatre was rejected as a hypothesis of volition, through minuscule movements of the gland activating the muscles, as these were perceived to require physical processes, not mental ones which did not operate in physical space. Due to Cartesian interactionism the vey concept of mind became regarded by Ryle (1949) as a category error, due to the categorical incompatibility of a dualistically separate mind and universe, preventing them from being able to interact upon one another, reducing mind to orphan status.

Rather than denying any possibility of a there being a relationship between such fundamentally different categories of existence, one shared and objectively verifiable and the other private to the individual alone as everything they experience, or denying the reality of the subjective

mind itself, interactive asymmetric complementarity asserts that it is because these categories are so different, asymmetric and complementary that the existential cosmos can become manifest through their interaction. For this to be self-consistent, there has to be a complementary interactive portal, through which the two aspects can affect one another, that is categorically consistent in each complementary domain.

Symbiotic Existential Cosmology solves this paradox, both through the biological features of the quantum universe and the nature of subjective conscious intentionality, but it does so confluent with empirical neuroscience and biophysics, without depending on any hypothetical exceptional quantum process that could later come to unravel the thesis, such as Hameroff-Penrose's ORCH. The physical side of the portal consists of the active brain state entering into self-organised criticality, where quantum uncertainty comes into play, causing the physical system to have an outcome not fully determined by the physical context. In turn, this enables subjective experience to make an autonomous personal intuitive hunch decision, based on intentional will, to intervene in the uncertain physical process to favour one of the permitted outcomes.

"Nature isn't classical, dammit, and if you want to make a simulation of nature, you'd better make it quantum mechanical." Richard Feynman (1982)

Because intentional volition is restricted to uncertain states, no causal conflict occurs between the uncertain physical contextual process and the mentally derived wilful intention that could arise, if autonomous volition – free will – extended to physically determinate states. Thus intentional subjectivity plays exactly the role we know is pivotal in tipping the balance of immediate uncertain environmental crises, such as a tiger strike, to ensure another round of survival against the odds in the environmentally uncertain vagaries of natural fate. This direct conscious intuitive awareness is shared by all eucaryote organisms with edge of chaos excitable membranes and remains consistent with empirical neuroscience and biophysics, while being fully interactive.

The **key redemptive feature** of Symbiotic Existential Cosmology for human survival in the biosphere is that it seeks to protect the **symbiotic diversity of life** in immortal perpetuity in paradise on the cosmic equator, as the climax manifestation of cosmological becoming, thus sacralising life itself as the bearer of conscious existence, over divine religious and spiritual attributes, such as deity. This is a foundation insight. NO religious or scientific cosmology does this to the same degree and it is essential for our survival as a species.

However, this opens up all the features of the pandora's box of psychedelic moksha, visionary and mystical experience, including mental powers, siddhis, and potential psychic phenomena as such, without invoking animal spirits, immortal souls, deity, doctrine or spirituality, focusing instead on the vision quest itself as the process of empirical investigation of subjective experience by mutual affirmation, complementing the verified empirical observations pivotal to the physical and natural sciences. It is confluent with notions such as Brahman as experienceable ultimate reality, the nierika portal of the Huichol peyote hunt and all direct intuitive mystical experiences. It can accept the notion of Ishvara/Ishvari as 'Elhoistic archetypal personae of the vision quest complementary to abstract Brahman as ultimate reality, without invoking moral deity or religious belief. It is open to investigating all forms of putative psychic phenomena as part of the affirmation process of the vision quest that is particularly associated with uncertain physical states displaying phenomena like synchronicity, but doesn't seek to reify religious notions, or psychic phenomena by trying to "prove" their absolute existence and refutes all forms of religious doctrine as contrary to the empirical nature of the autonomous subjective discovery process.

(e) **Dark Noosphere Theories**

Some theories try to assert a variety of other notions, such as that gravitation, rather than the quantum forces, somehow forms a substrate for conscious subjectivity, leading to concepts like a dark matter (Werbos 2019, Davis 2019), or dark energy (Bogomolov 2020, 2022), noosphere, in

which an occult collective ‘informational’ consciousness might operate. However (a) Conventional gravity already has a clear role, along with the quantum forces in generating conscious life, through the negentropic planetary-solar interface; (b) The only confirmed evidence we have for dark matter comes from the rotation of galaxies under conventional gravity and putative dark matter particles like axions remain hypothetical and fall within the regime of quantum wave-particles and (c) There is a lack of affirmed empirical evidence for an occult noosphere, unlike visionary experience itself, which has a long and extensive empirical basis.

Discovering Life, the Universe and Everything

I have experienced every type of hallucinogenic agent known to science and communed with sacred mushrooms for half a century and have faithfully kept my visionary covenant with them both before and since since the key event I now describe. Last June, after a seven-year break, due to nearly being blinded by acute closed angle glaucoma, exacerbated by dilating my pupils on psychedelics, recently cured by total lens replacement, I took another plunge, using a mild dose suitable for a healthy 76 year old, in an activity-enhancing mushroom lemon tea. At the peak, I sank into deep meditation, framing the ultimate question: “What is the answer to life, the universe and everything”? I fell deep down into the entheogenic abyss, which opened out into the moksha epiphany of being, of transfiguring intensity, utterly compassionate of the mortal coil. This comes by many names, the mind-at-large to Aldous Huxley, Brahman-atman to the Upanishads, and the All in Yeshua’s words, in the Gospel of Thomas. I emerged, galvanised and invigorated by a seemingly impossible task – literally saving the diversity of conscious life of the entire universe, not to neglect, in passing, the lost sheep of Israel! Here’s how it can be done!

Left: Conversation with Deepak Chopra

Right: The Efficacy of Subjective Conscious Physical Volition

As a researcher in quantum chaos and neuroscience, I struggled to reassemble the scattered shards of my physical worldview. Over weeks, this metamorphosed into “The Symbiotic Cosmology of Perennial Conscious Existence”, a creative commons monograph on Research Gate – augmenting physical cosmology with its universal complement in conscious existence, in three interlocking components, biogenic, panpsychic and symbiotic.

This cosmology is fully consistent with quantum physics and neuroscience but resolves the three central paradoxes of conscious existence: (1) The hard problem of consciousness (why subjective experience exists); (2) the physical efficacy of conscious volitional will (can our subjective experience of purposive intent, that we depend on to do anything, actually affect the world around us) and (3) the cosmological role of conscious life in the universe.

This discovery is of critical importance for humanity’s survival, although it may seem paradoxical, given its source, because the diversity of conscious life becomes the consummating climax of cosmic evolution – in an all-encompassing biological, psychic and cosmological symbiosis. And this comes with the same urgent galvanising responsibility, amid an acute planetary crisis of climate, habitat and biodiversity, to save the diversity of life from an impending human-caused mass extinction, which could well precipitate our own demise, through failing to live symbiotically within the biosphere on which we depend. Species need to not just survive, but survive in sufficient genetic diversity, to prosper and evolve. Humanity’s survival over evolutionary time scales as a fit species, in the biosphere, requires returning half the Earth’s natural habitats to the several million species with which we co-depend. As noted on the cover, it also requires ending the mutually assured destruction of the nuclear arsenal which leaves the Earth on a hair trigger instability of accidental annihilation.

The discovery is also about hard real world reality, because it gives us back conscious volitional autonomy over the world – our integral sense of personal “agency” that materialistic science stole from us in the Copernican revolution, enshrined in Newton’s laws of motion, now relentlessly entangled in the teeming uncertainty of the quantum universe. Making our scientific description consistent with our conscious autonomy also makes it consistent with civil and criminal law, in which intent, as intelligent volition, is pivotal to accountability for our actions. Incorporating conscious volition into cosmology also gives empirical science back its ethical and existential validity over prescriptive religious belief, in the true pursuit of knowledge.

Fig 18: Pupil dilated by psilocin.

The key role of life in the universe is clearly expressed in the first component – fractal biogenic cosmology. We know by our very existence that life is capable of emerging and existing in the physical universe, but there is an underlying reason. The four forces of nature, emergent from cosmological symmetry-breaking, give rise to interactive chain reactions which compound quarks, into baryons, atomic nuclei and fractal molecular structures, because of non-linearities associated with nuclear and chemical bonding. While the energetics of biology is dwarfed to insignificance by the strongest cosmological forces, resulting in galaxies, black holes and stars, the quantum structural pathway to full interaction of the four forces leads to atoms, fractal biomolecules, organelles, cells, tissues and the conscious brain – paradise on the cosmic equator in space-time, once a first generation of stars have made the chemical elements and evolution has had time to result in conscious organisms.

Living in the quantum universe, we have no idea whether complex unstable phenomena, such as brain processes, are causally closed. We can’t assume mechanism rules when uncertainty enters into the equation and processes at the edge of chaos can amplify it. This applies particularly to unstable brain processes, which are assumed, without real evidence, to be causally closed. Pure materialism, particularly in neuroscience, has become an unscientific doctrinal “publish or perish” belief system, having little more evidential credibility than religious fundamentalism. Conscious experience is our sole avenue to know and understand the physical universe. Although we have to respect the fundamental nature of physical existence, to survive in the world, the totality of our knowledge of the physical reality of the world around us is established exclusively through our subjective consciousness, as a consensual experience of conscious participants, complementing our individual dreams and visions.

Since we all believe and act on the basis that we have autonomous conscious volition, we need to determine what type of cosmology is consistent with conscious decision-making in the universe we inhabit. It must be one in which the subjective conscious mind can affect the objective physical brain, so by Occam’s razor, we eliminate all cosmologies which fail this veridical test, and out the window goes pure materialism! The brain may have some low energy quantum physics going on to support conscious processing, but it is just some ordinary organic matter that clearly obeys the four quantum forces – colour, weak, electromagnetic and gravity, so we immediately have a situation where, in at least some forms of matter – (a) physical causality is not closed and (b) the physics has a complementary subjective aspect. Conscious volitional autonomy thus implies natural panpsychism!

This is already a panpsychic cosmology, because subjectivity has become a fundamental property of nature. This is why the hard problem is cosmological, not just a neuroscience problem and this is not a form of dualism! Just as the wave and particle aspects of physics are complementary rather than distinct, so are the physical universe and subjective mind. Gilbert Ryle’s Cartesian “ghost in the machine” thus does not apply!

In the second component, Darwinian panpsychism – which I coined from Charles Darwin’s comment that free will could run all the way from the “puppy” to the “polypes”, the subjective aspect becomes complementary to the universe as a whole, encapsulated in the many and various forms we experience as organismic consciousness, echoing Erwin Schrödinger’s statement: “The number of minds in the universe is one”.

The quantum universe is a causal process punctuated by quantum uncertainty. To enable subjective consciousness to influence brain function without causal conflict, means subjective consciousness applies to situations where uncertainty is key – for example at unstable global tipping points in brain dynamics, where ion channel thresholds are crossed at the quantum level in a way the brain becomes sensitive to, through edge of chaos dynamics and stochastic resonance. This is precisely what is required to make sometimes split-second intuitive decisions, in exactly the

situations where consciousness is key – avoiding uncertain threats to our survival, through environmental crises that can be irreducibly intractable to compute.

What then is quantum subjectivity? Each particle is “latently conscious” – probabilistically moulded by its wave function, expressing its entangled quantum history and future under special relativity. Each single quantum instance is also a single idiosyncratic event, in which the particle is randomly expressed within the wave function amplitude. This idiosyncrasy corresponds to its free will. Unstable quantum processes, including edge-of-chaos, biogenesis and excitable prokaryote cells, likewise inherit this latent complementary subjective aspect.

What about the emergence of consciousness? In the eucaryote endosymbiosis, when an archaean species engulfed respiring bacteria to form our energetic mitochondria, there was a discrete transition to “cellular sentience”, because the cell membrane became freed from energy transduction and became available for sensitivity to quantum “sense” modes and social signalling, with coordinated excitability functioning as a “conscious” organiser using the same cellular processes and receptors as in neurons. Subjective consciousness thus predates nervous system computation by a good billion years. Informational models of consciousness, such as IIT integrated information theory and AST attention schema theory, thus incorrectly have the cart before the horse. The ensuing story, from the amoeba to humanity, is bridged by the social amoeba *Dictyostellium*, which has both individual cellular and coordinated organismic modes. The brain later evolves as a massively parallel organ, processing experience, operating as a tightly-coupled society of social amoebae communicating seamlessly with pre-existing sentient consciousness via a coordinated form of organismic edge-of-chaos excitability, using the same social signalling molecules that evolved in single celled species.

Existential cosmology is empirically verifiable. Objective empiricism has become technologically facile, on all scales, from the quantum to the universe. By contrast, subjective empiricism comes from subjective experiential reports of both everyday mental states and deeper transformative experiences, as well as volitional will evident in behaviour. All three are well established and as old as human culture, complemented by our awareness of purposive sentient activity in animal behaviour, indicating volition down as far as founding single celled eucaryotes. The success of psychedelics in alleviating depressive and terminal illness and documented genuine spiritual experiences, described as either religious, or of “ultimate reality” by the subject, attests to their validity and statistical significance as empirical scientific findings.

The third component is symbiosis – genetic, cellular, organismic, biospheric, psychic and cosmological. Complex life evolved through a complementary endosymbiosis between the two prokaryote kingdoms – archaea and bacteria. Eucaryote endosymbiosis is necessary for complex life to exist, demonstrating that symbiosis, as an edge-of-chaos climax, transcends living systems lacking such complementation. Sexuality, foundational to eucaryotes, is also a form of genetic symbiosis, in which two or more strains are locked into a symbiotic role, asymmetric in sperm-ovum fertilisation in animals, also called sexually antagonistic co-evolution, due to differing male and female reproductive strategies, as in the human sex wars of patriarchal domination. The human genome is also in functional genetic symbiosis, with 46% being endogenous viral and transposable elements which, although selfish, have become key to coordinated gene regulation and evolution. Symbiosis is also biospheric. Life is not just a competitive capitalistic struggle of tooth and claw, but survival of the most effective biospheric symbionts, in which predator, prey, parasite and host, moderate boom and bust dynamics, in edge-of-chaos biodiversity climax.

Founding gatherer-hunter cultures responsible for human cultural emergence, from the San Bushmen to the Congo Pygmies have achieved biospheric symbiosis through an animistic ¹⁵ view of nature as interconnected relationships, in which animals and natural forces are conceived as having agency and personhood. Panpsychist existential cosmology shares these symbiotic features of animism which also underlies the later emergence of religious systems. Both materialistic science, and its technological development and religions asserting dominion over nature and a direct prisoners' dilemma tragedy of the commons (Hardin 1968) have brought about the impending human-induced mass extinction of life, so the interconnectedness with nature of the animistic/panpsychic world view becomes pivotal to our future survival, as a cultural expression of symbiosis between natural diversity and human culture.

Symbiosis is also psychic and cosmological. The natural correction to human induced mass extinction of life due to our tribally-based species dominance is conscious existence reaching edge-of-chaos climax, in which planetary guardianship is not the exclusive possession of a single dominant species *Homo sapiens*, but is achieved in psychic

¹⁵ *animism* – the belief that all things – animals, plants, rocks, rivers, weather systems etc. possess a distinct spiritual essence – as animated and alive.

symbiosis with entheogenic species, which have evolved in such a way as to return egotistical consciousness to the primary consciousness noted in research studies. By opening the doors of perception to the deeper cosmic reality subjective consciousness contains, psychedelics manifest psyche, thus constituting the subjective complement to the LHC in cosmological physics, also enabling the universe to come alive and know itself in us, in cosmological symbiosis. It remains categorically unclear that the universe is able to manifest its existence in the absence our conscious experience of it.

The lesson from the prisoners' dilemma and evolutionary game theory is that, to advance this theory in adequate time to mitigate and alleviate a mass extinction of life, I can't afford to adopt a simple polite cooperative stance. Human motivation is not going to simply accept a veridical theory of symbiotic existence that comes out of deep left field. This is going to take a lionesses claws to succeed in time to have any chance of a soft landing for the diversity of life on our planet. I will thus try to be firm but fair, but invoking tit-for-tat as a fall-back response, in the face of consistent defection, against protecting the diversity of life from mass extinction.

The Central Enigma: What IS the Conscious Mind?

To understand the nature of consciousness, we have to address the fact that the term consciousness is enigmatic and multifaceted, in a way which brings to mind the apocryphal tale of the 100 eskimo words for snow. Both 'mind' and 'consciousness' present a varied array of associated words and concepts, which we need to clarify, to even begin to close in on the central enigma, which the terms present to us.

Mind conjures up a plethora of concepts from the entire realm of conscious experience "what comes to mind", through the rational mind of thought and language based reasoning, minding i.e. emotional caring, or "do you mind?" i.e object, mindfulness or focused concentration, to absent-, clear- or small-

mindedness to the in attentive or mindless blunders many of us make, despite ourselves.

Consciousness, at its simplest, is sentience and awareness of internal and external existence. However, its nature has led to millennia of analyses, explanations and debates by philosophers, theologians, linguists, and scientists. Opinions differ about what exactly needs to be studied or even considered consciousness. It is the active process of attending to and engaging subjective experience, either internally, or through the physical senses. It can mean everything from subjective consciousness, the root capacity to have subjective experiences at all, through awake alertness, as opposed to the slumber, or coma, the state of being conscious as opposed to unconsciousness, through the fuzzy boundary between sub-conscious, pre-conscious, or un-conscious processing that accompanies conscious attention and cognition, to the restrictive idea of self-consciousness – knowing that you know that you know. A conscious state is thus one which has a higher-order accompanying thought which is about the state in question. We also have "conscious of" in the sense of being aware of a specific phenomenon or thing.

Volition is the efficacy of intentional conscious states to affect the physical universe through subjective decision making (in the brain) and active behaviour (in the world).

Wikipedia has the following introductory descriptions, chosen because they are a product of a social process of consensual agreement as to their meaning and content:

"**Mind** collectively refers to the aspects of intellect and consciousness manifested as combinations of thought, perception, memory, emotion, will and imagination; mind is the stream of consciousness. It includes all of the brain's conscious processes. This denotation sometimes includes, in certain contexts, the working of the human unconscious or the conscious thoughts of animals. "Mind" is often used to refer especially to the thought processes of reason."

"**Consciousness** has been defined loosely as a constellation of attributes of mind such as subjectivity, self-awareness, sentience, and the ability to perceive a relationship between oneself and one's environment. It has been defined from a more biological and causal perspective as the act of autonomously modulating attentional and computational effort, usually with the goal of obtaining, retaining, or maximizing specific parameters (food, a safe environment, family,

mates). Consciousness may involve thoughts, sensations, perceptions, moods, emotions, dreams, and an awareness of self, although not necessarily any particular one or combination of these."

The **etymologies** of consciousness and mind are very different, as noted in the glossary below. **Conscious**, dating from 1600 harks back to Latin *com* "with," + *scire* "to know" – originally to cut or divide as in incise and scissors. By contrast **mind** as "that which feels, wills, and thinks; the intellect," dates to the 1100s and reflects proto-Germanic *muns* "thought," and *minne* "loving memory".

Although these contain a constellation of meanings, in which mind is sometimes focused on the attributes of reasoned, or even language-based thought, and consciousness is sometimes given the more restrictive meaning of self-awareness, or a more general meaning of simply being aware, both contain a central arena of subjectivity and sentience, that typifies the living condition and accompanies us all our lives from birth to death and is the subjective experiential basis through which we perceive and understand the physical world around us, while conceding that the boundaries between consciousness and the sub- or unconscious may be fuzzy, both in varied brain states, from waking thought to sleep and coma, and in complex autonomous processes, which go on below the level of immediate awareness, during activities like driving a car.

The central enigma we are exploring is not self-consciousness, but subjective consciousness – the capacity of a conscious sentient being to have a subjective experience of the existential condition, both of the everyday world, and of dream, memory and reflection, hallucination, psychedelic reverie, and other forms of internal subjective experience, not directly correlated with the immediate events of the physical world.

Etymological Glossary (Etymonline)

The subjective includes **consciousness, sentience, mind, emotion, illumination and volition**. In my definition (see 2 below), **subjective** is "existing in the conscious mind" (the mind as "the thinking subject"). I see **mind** as the organ of thought and cognition. **Con-scious** (Latin "with knowing") is the active word that defines subjective consciousness.

subjective (adj.) c. 1500, (1) "characteristic of one who is submissive or obedient," from Late Latin *subiectivus* "of the subject, subjective," from *subiectus* "lying under, below, near bordering on," figuratively "subjected, subdued" (see *subject* (n.)). (2) In early Modern English as "existing, real;" more restricted meaning "**existing in the mind**" (**the mind as "the thinking subject"**) is from 1707, popularized by Kant and his contemporaries; thus, (3) in art and literature, "personal, idiosyncratic" (1767).

conscious (adj.) c. 1600, "knowing, privy to" (poetic), from Latin *consciūs* "knowing, aware," from *conscire* "be (mutually) aware," from assimilated form of *com* "with," or "thoroughly" (see *con-*) + *scire* "to know" (see *science*). The Latin word probably is a loan-translation of Greek *syneidos*. The sense of "knowing or perceiving within oneself, sensible inwardly, aware" is from 1630s, perhaps a shortening of *conscious to oneself* (1620s). Also compare the Latin sense evolution in *conscience* and *sentience*. From 1650s as "aware (of a fact)." Sense of "active and awake, endowed with active mental faculties" is from 1837. **skai-* Proto-Indo-European root meaning "to cut, split," extension of root **sek-* "to cut." as in scission, schism, incise.

consciousness (n.) 1630s, "internal knowledge," from *conscious* + *-ness*. Meaning "state of being aware of what passes in one's own mind" is from 1670s; meaning "state of being aware" of anything is from 1746. Consciousness-raising is attested from 1968.

conscience (n.) c. 1200, "faculty of knowing what is right," originally especially to Christian ethics, later "awareness that the acts for which one feels responsible do or do not conform to one's ideal of right," later (late 14c.) more generally, "sense of fairness or justice, moral sense." This is from Old French *conscience* "conscience, innermost thoughts, desires, intentions; feelings" (12c.) and directly from Latin *scientia* "a joint knowledge of something, a knowing of a thing together with another person; consciousness, knowledge;"

experience (n.) late 14c., "observation as the source of knowledge; actual observation; an event which has affected one," from Old French *esperience* "experiment, proof, experience" (13c.), from Latin *experientia* "a trial, proof, experiment; knowledge gained by repeated trials," from *experientem* (nominative *experiens*) "experienced, enterprising, active, industrious," present participle of *experiri* "to try, test," from *ex* "out of" (see *ex-*) + *peritus* "experienced, tested," from PIE **per-yo-*, suffixed form of root **per-* (3) "to try, risk." Meaning "state of having done something and gotten handy at it" is from late 15c.

sentient (adj.) 1630s, "capable of feeling, having the power of or characterized by the exercise of sense-perception," from Latin *sentientem* (nominative *sentiens*) "feeling," present participle of *sentire* "to feel" (see **sense** (n.)). Related: *Sentiently*.

sentience (n.) 1817, "faculty of sense; sentient character or state, feeling, consciousness, susceptibility to sensation;" 1817, "faculty of sense; sentient character or state, feeling, consciousness, susceptibility to sensation;" see **sentient** + **-ence**. Related: *Sentiency* (1796).

mind (n.) "that which feels, wills, and thinks; the intellect," late 12c., *mynd*, from Old English *gemynd* "memory, remembrance; state of being remembered; thought, purpose; conscious mind, intellect, intention," Proto-Germanic **ga-mundiz* (source also of Gothic *muns* "thought," *munan* "to think;" Old Norse *minni* "mind;" German *Minne* (archaic) "love," originally "memory, loving memory"),

from suffixed form of PIE root **men-* (1) "to think," with derivatives referring to qualities of mind or states of thought. Meaning "mental faculty, the thinking process" is from c. 1300. Sense of "intention, purpose" is from c. 1300. From late 14c. as "frame of mind. mental disposition," also "way of thinking, opinion." "Memory," one of the oldest senses, now is almost obsolete except in old expressions such as bear in mind (late 14c.), call to mind (early 15c.), keep in mind (late 15c.). Mind's eye "mental view or vision, remembrance" is from early 15c. To pay no mind "disregard" is recorded by 1910, American English dialect. To make up (one's) mind "determine, come to a definite conclusion" is by 1784. To have a mind "be inclined or disposed" (to do something) is by 1540s; to have half a mind to "to have one's mind half made up to (do something)" is recorded from 1726. Out of (one's) mind "mad, insane" is from late 14c.; out of mind "forgotten" is from c. 1300; phrase time out of mind "time beyond people's memory" is attested from early 15c.

existence (n.) late 14c., "reality," from Old French *existence*, from Medieval Latin *existentia/existentia*, from *existentem/exsistentem* (nominative *existens/exsistens*) "existent," present participle of Latin *existere/exsistere* "stand forth, come out, emerge; appear, be visible, come to light; arise, be produced; turn into," and, as a secondary meaning, "exist, be;" from *ex* "forth" (see *ex-*) + *sistere* "cause to stand," from PIE **si-st-*, reduplicated form of root **sta-* "to stand, make or be firm."

essence (n.) late 14c., *essencia* (respelled late 15c. on French model), from Latin *essentia* "being, essence," abstract noun formed (to translate Greek *ousia* "being, essence") from *essent-*, present participle stem of *esse* "to be," from PIE root **es-* "to be." Originally "substance of the Trinity;" the general sense of "basic element of anything" is first recorded in English 1650s, though this is the underlying notion of the first English use of essential. Meaning "ingredient which gives something its particular character" is from c. 1600, especially of distilled oils from plants (1650s), hence "fragrance, perfume" (17c.). In 19c. U.S., essence-peddler could mean "medical salesman" and "skunk."

emotion (n.) 1570s, "a (social) moving, stirring, agitation," from French *émotion* (16c.), from Old French *emouvoir* "stir up" (12c.), from Latin *emovere* "move out, remove, agitate," from assimilated form of *ex* "out" (see *ex-*) + *movere* "to move" (from PIE root **meue-* "to push away"). Sense of "strong feeling" is first recorded 1650s; extended to any feeling by 1808.

illumination (n.) late 14c., "spiritual enlightenment," from Late Latin *illuminationem* (nominative *illuminatio*), noun of action from past participle stem of Latin *illuminare* "to throw into light, make bright, light up;" figuratively, in rhetoric, "to set off, illustrate," from assimilated form of *in-* "in, into" (from PIE root **en* "in") + *lumen* (genitive *luminis*) "light," from suffixed form of PIE root **leuk-* "light, brightness." Meaning "action of lighting" in English is from 1560s; sense of "intellectual enlightenment" is from 1630s.

enlightenment (n.) 1660s, "action of enlightening," from enlighten + -ment. Used only in figurative sense, of spiritual enlightenment, etc. Attested from 1865 as a translation of German *Aufklärung*, a name for the spirit of independent thought and rationalistic system of 18c. Continental philosophers.

enlighten (v.) 14c., "to remove the dimness or blindness" (usually figurative, from one's eyes or heart); see *en-* (1) + *lighten* (v.2). From 1660s as "supply with intellectual light." Literal senses are later and less common in English: "put light in" is from 1580s; "shed light upon" is from 1610s.

objective (adj.) 1610s, originally in the philosophical sense of "considered in relation to its object" (opposite of subjective), formed on pattern of Medieval Latin *objectivus*, from *objectum* "object" (see *object* (n.)) + -ive. Meaning "impersonal, unbiased" is first found 1855, influenced by German *objektiv*.

physical (adj.) early 15c., *phisical*, "medicinal" (opposed to surgical), from Medieval Latin *physicalis* "of nature, natural," from Latin *physica* "study of nature" (see *physic*). The meaning "pertaining to matter, of or pertaining to what is perceived by the senses" is from 1590s; the meaning "having to do with the body, corporeal, pertaining to the material part or structure of an organized being" (as opposed to mental or moral) is attested from 1780. The sense of "characterized by bodily attributes or activities, being or inclined to be bodily aggressive or violent" is attested from 1970.

science (n.) mid-14c., "state or fact of knowing; what is known, knowledge (of something) acquired by study; information;" also "assurance of knowledge, certitude, certainty," from Old French *science* "knowledge, learning, application; corpus of human knowledge" (12c.), from Latin *scientia* "knowledge, a knowing; expertness," from *sciens* (genitive *scientis*) "intelligent, skilled," present participle of *scire* "to know."

nature (n.) late 13c., "restorative powers of the body, bodily processes; powers of growth;" from Old French *nature* "nature, being, principle of life; character, essence," from Latin *natura* "course of things; natural character, constitution, quality; the universe," literally "birth," from *natus* "born," past participle of *nasci* "to be born," from PIE root **gene-* "give birth, beget." By mid-14c. as "the forces or processes of the material world; that which produces living things and maintains order." From late 14c. as "creation, the universe;" also "heredity, birth, hereditary circumstance; essential qualities, inherent constitution, innate disposition" (as in *human nature*); also "nature personified, Mother Nature." *Nature* and *nurture* have been paired and contrasted since Shakespeare's "Tempest."

natural (adj.) c. 1300, *naturel*, "of one's inborn character; hereditary, innate, by birth or as if by birth;" early 14c. "of the world of nature (especially as opposed to man)," from Old French *naturel* "of nature, conforming to nature; by birth," and directly from Latin *naturalis* "by birth, according to nature," from *natura* "nature" (see **nature**). Of events, features, etc., "existing in nature as a result of natural forces" (that is, not caused by accident, human agency, or divine intervention), late 14c.

resplendence (n.) "vivid brightness, brilliance, splendor," early 15c., from Late Latin *resplendentia*, abstract noun from present-participle stem of Latin *resplendens* "**brilliant, radiant**".

religion (n.) c. 1200, *religioun*, "state of life bound by monastic vows," also "action or conduct indicating a belief in a divine power and reverence for and desire to please it," from Anglo-French *religiun* (11c.), Old French *religion*, *relegion* "piety, devotion; religious

community," and directly from Latin *religionem* (nominative *religio*) "respect for what is sacred, reverence for the gods; conscientiousness, sense of right, moral obligation; fear of the gods; divine service, religious observance; a religion, a faith, a mode of worship, cult; sanctity, holiness," in Late Latin "monastic life" (5c.). This noun of action was derived by Cicero from *relegere* "go through again" (in reading or in thought), from *re-* "again" (see *re-*) + *legere* "read" (see lecture (n.)). However, popular etymology among the later ancients (Servius, Lactantius, Augustine) and the interpretation of many modern writers connects it with **religare** "to bind fast" (see *rely*), via the notion of "place an obligation on," or "bond between humans and gods.

sacramental (adj.) "of, pertaining to, or constituting a sacrament," late 14c., from Old French *sacramental* and directly from Late Latin *sacramentalis*, from *sacramentum* (see **sacrament**). As a noun, "religious practice or object," mid-15c.

sacrament (n.) late Old English, in Christian use, "an outward and visible sign of inward and spiritual grace," especially "a sacrament of the Church, one of the religious ceremonies enjoined by Christ or the Church," and later specifically "the sacrament of the Eucharist" (c. 1300), from Old French *sacrament* "consecration; mystery" (12c., Modern French *sacrement*) and directly from Latin *sacramentum*, "a solemn oath" (source also of Spanish *sacramento*, German *Sakrament*, etc.), from *sacrare* "to consecrate" (see **sacred**).

duality (n.) "twofold nature, state of being two or divided in two," late 14c., from Late Latin *dualitas*, from Latin *dualis* "that contains two; the dual number, duality," from *duo* "two" (from PIE root **dwō-* "two"). An instance of opposition or contrast between two concepts or two aspects of something. In mathematics, a duality translates concepts, theorems, or structures in a one-to-one fashion.

complementarity (n.) "a complementary relation or situation," 1908, a term in physics, from **complementary** + *-ity*.

complementary (adj.) 1620s, from **complement** (n.) + *-ary*. Sense of "forming a complement, mutually completing each other's deficiencies," is attested by 1794.

complement (n.) late 14c., "means of completing; that which completes; what is needed to complete or fill up," from Old French *complément* "accomplishment, fulfillment" (14c., Modern French *complément*), from Latin *complementum* "that which fills up or completes," from *complere* "fill up," from *com-*, here probably as an intensive prefix (see *com-*), + *plere* "to fill"

interactive (adj.) "acting upon or influencing each other," 1832, from **interact** (v.), probably on model of **active**.

supersensible Beyond the range of what is perceptible by the senses; **not belonging to the experienceable physical world.**

astral (adj.) c. 1600, "pertaining to the stars," from Late Latin *astralis*, from Latin *astrum* "star," from Greek *astron* "a star" (from PIE root **ster-* (2) "star"). The meaning "pertaining to supersensible substances" is from 1690s, popularized late 19c. in Theosophy.

will (v.1) Old English **willan*, *wyllan* "to wish, desire; be willing; be used to; be about to" (past tense *wolde*), from Proto-Germanic **willjan* (source also of Old Saxon *willian*, Old Norse *vilja*, Old Frisian *willa*, Dutch *willen*, Old High German *wellan*, German *wollen*, Gothic *wiljan* "to will, wish, desire," Gothic *waljan* "to choose"). The Germanic words are from PIE root **wel-* (2) "to wish, will" (source also of Sanskrit *vrnoti* "chooses, prefers," *varyah* "to be chosen, eligible, excellent," *varanam* "choosing;" Avestan *verenav-* "to wish, will, choose;" Greek *elpis* "hope;" Latin *volo*, *velle* "to wish, will, desire;")

free will (n.) the power of acting without the constraint of necessity or fate; the ability to act at one's own discretion.

volition (n.) 1610s, from French *volition* (16c.), from Medieval Latin *volitionem* (nominative *volitio*) "will, volition," noun of action from Latin stem (as in *volo* "I wish") of *velle* "to wish," from PIE root **wel-* (2) "to wish, will" (see **will** (v.)). Related: *Volitional*.

truth (n.) Old English *triewð* (West Saxon), *treowð* (Mercian) "faith, faithfulness, fidelity, loyalty; veracity, quality of being true; pledge, covenant," from Proto-Germanic *treuwaz* "having or characterized by good faith," from PIE **drew-o-*, a suffixed form of the root **deru-* "be firm, solid, steadfast." Sense of "something that is true" is first recorded mid-14c. Meaning "accuracy, correctness" is from 1560s. English and most other IE languages do not have a primary verb for "speak the truth," as a contrast to **lie** (v.).

void (adj.) c. 1300, "unoccupied, vacant," from Anglo-French and Old French *voide*, *viude* "empty, vast, wide, hollow, waste, uncultivated, fallow," as a noun, "opening, hole; loss," from Latin *vocivos* "unoccupied, vacant," related to *vacare* "be empty," from PIE **wak-*, extended form of root **eue-* "to leave, abandon, give out."

fertility (n.) mid-15c., *fertilite*, from Old French *fertilité*, from Latin *fertilitatem* (nominative *fertilitas*) "fruitfulness, fertility," from *fertilis* "fruitful, productive"

fecundity (n.) early 15c., from Latin *fecunditatem* (nominative *fecunditas*) "fruitfulness, fertility," from *fecundus* "fruitful, fertile" (see **fecund**). The ability to produce an abundance of offspring or new growth; fertility. "*multiply mated females show increased fecundity*"

virility (n.) "period of manhood," 1580s, from French *virilité*, from Latin *virilitatem* (nominative *virilitas*) "manhood," from *virilis* "of a man, manly, worthy of a man," from *vir* "a man, a hero," from PIE root **wi-ro-* "man." Meaning "power of procreation, capacity for sexual intercourse" is from 1590s; sense of "manly strength" is recorded from c. 1600.

eternal (adj.) late 14c., from Old French *eternel* "eternal," or directly from Late Latin *aeternalis*, from Latin *aeternus* "of an age, lasting, enduring, permanent, everlasting, endless," contraction of *aeviternus* "of great age," from *aevum* "age" (from PIE root **aiw-* "vital force, life; long life, eternity").

immortal (adj.) late 14c., "deathless," from Latin *immortalis* "deathless, undying" (of gods), "imperishable, endless" (of fame, love, work, etc.), from assimilated form of *in-* "not, opposite of" (see **in-** (1)) + *mortalis* "mortal" (from PIE root **mer-* "to rub away, harm," also "to die" and forming words referring to death and to beings subject to death).

Biocrisis and Resplendence : Fermi Extinction and Planetary Reforewing

Planet Earth is heading into multiple serious human-caused self-extinction scenarios – habitat destruction planet wide, climate crisis that may become irreversible, mass extinction of biodiversity, exponential population instability, cumulative risk of nuclear holocaust, generalised AI takeover due to materialist physicalism failing to recognise we are NOT just machines, excessive brittle dependence on technology to feed ourselves, failure to protect our food species, failure to protect the genetic diversity of the planet, the failure of collective leadership and decision-making processes to address or protect human viability in a tragedy of the commons. If this doesn't actually cause our extinction as a species, it will certainly destroy our blue-green paradise and make human culture perilous to unliveable. There is no techno-fix for this. We should be envisaging another 500 million years of sanctuary to discover the ultimate mysteries of existence. No utopian pretence will save us. These are the hard facts of life we are failing to address.

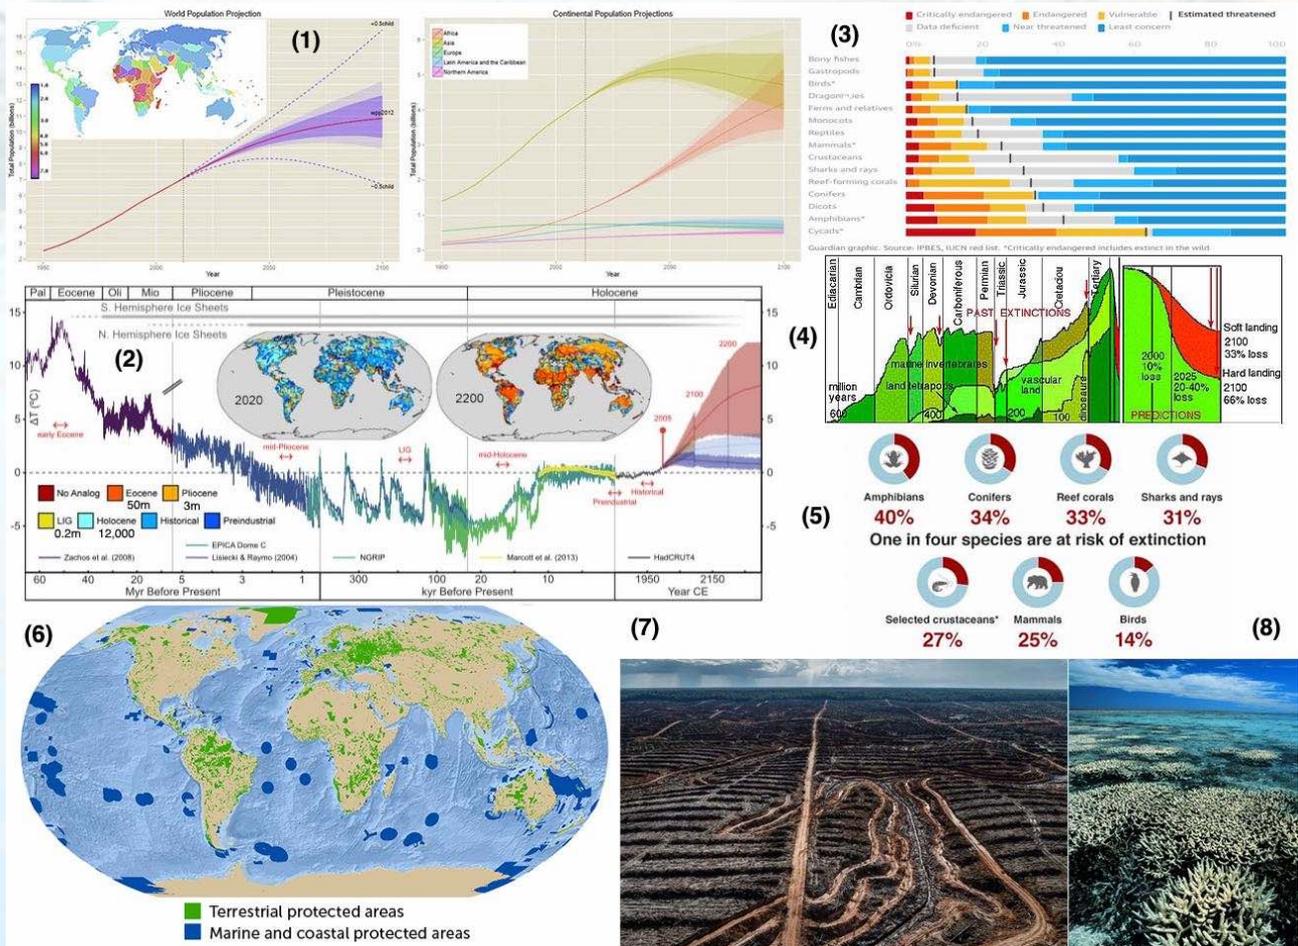

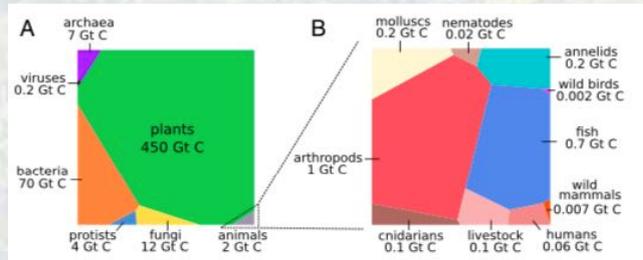

Fig 19: (1) World population is predicted to continue to rise through to 2100 (Gerland et al. 2014), with the majority of the increase in sub-Saharan Africa (inset). This will increase the world population to 10 billion, with immense pressure on the African continent’s carrying capacity and pressure of migration on all continents. (2) Predicted long term effects of climate change (Burke et al. 2018) could lead to a catastrophic cumulative heating over millennia, taking the planet back to the previous Eocene peak hot period 50 million years ago, placing many of the plant and animal species on which we depend well out of their evolved climate zone, potentially leading to human extinction because of our continuing dependence on highly evolved plant and animal species (Burke et al. 2018). (3) Threatened species by group (Guardian). (4) This situation is unsustainable and leads directly to mass extinctions of biodiversity, which would take up to 50 million years to be addressed by subsequent evolution, as exemplified by previous mass extinctions. (5) Species losses of a variety of animal and plant phyla. The incipient sixth mass extinction that started in the Late Pleistocene has already put over a quarter of mammal species under acute risk of extinction (Leakey & Lewin 1995, Kolbert 2014, 2021, Davis et al. 2018, Dawson 2016). Detailed calculations of mammalian species indicate a time frame of millions of years to recover from the current mass extinctions, by evolving new life forms, but those lost will never be recovered. Insects are also suffering catastrophic population decline due to habitat destruction. (7) Protected areas are manifestly insufficient to protect biological and genetic diversity. International agreement is urgently needed to extend these areas. (8) Scorched-earth clear felling for palm oil plantations has felled a third of Borneo’s forest almost overnight. Such wholesale habitat destruction is even worse than burning the rainforest because all living diversity is eradicated in favour of one monoclonal species. (8) Coral bleaching shows how climate change can lead to wholesale mass extinction of species in some of the most intense oceanic biodiversity hotspots, leading to a barren ocean.

Protecting the biospheric diversity of life is critical for our own survival, as is avoiding climate crisis and unravelling the ever-present risk of nuclear Armageddon. The rape of Gaia¹⁶ – “Mother Earth” by the patriarchal imperatives of dominion over nature and business-as-usual competitive exploitation is a suicidal insanity running through our cultural mind set, which humanity currently lacks the collective insight to alleviate. Intervention in the common good is urgently necessary. This is precisely what I experienced in being galvanised to write this work after a quantum change experience on sacred mushrooms, following a seven year karmic drought due to acute closed angle glaucoma, risking blindness if my pupils became dilated. For the “mind at large” to awaken even for a moment and become acutely aware of the carnage wrought upon the planet through the relentless exploitative impact of a single species *Homo sapiens*, it is obvious that, by its very compassion for the mortal coil, it will impart to the beholder an urgent tenacity to protect the living planet.

The global biomass of biodiversity

Human intrusion into all available habitats causing wholesale natural habitat destruction means that the biomass of livestock is over 14 times that of all wild mammals and the biomass of humans is over 8.5 times. Bar-On et al. (2018) assemble the overall biomass composition of the biosphere, establishing a census of the ~550 gigatons of carbon (Gt C) of biomass distributed among all of the kingdoms of life. We show that terrestrial biomass is about two orders of magnitude higher than marine biomass and estimate a total of ~6 Gt C of marine biota, doubling the previous estimated quantity. The global marine biomass pyramid contains more consumers than producers. Finally, we highlight that the mass of humans is an order of magnitude higher than that of all wild mammals combined and report the historical impact of humanity on the global biomass of prominent taxa, including mammals, fish, and plants.

Fig 19b: **The biomass of humans plus livestock as of 2018 is 22.5 times that of all wild mammals.** Graphical representation of the global biomass distribution by taxa. (A) Absolute biomasses of different taxa are represented by the area of each cell being proportional to that taxa global biomass. (B) Absolute biomass of different animal taxa. Related groups such as vertebrates are located next to each other.

The global biomass of wild mammals

A study by scientists at Israel’s Weizmann Institute of Science (Greenspoon et al. (2023) concludes that wild land mammals alive today have a total mass of 22m tonnes. Humanity now weighs in at a total of around 390m tonnes. Domesticated species, such as sheep and cattle, in addition to other hangers-on such as urban rodents, add a further 630m tonnes. **Thus as of 2023 wild land mammals represent only 22/(390+630)=0.02 or 2%. So the figure has risen from 22.5 2to 46 times from 2018.**

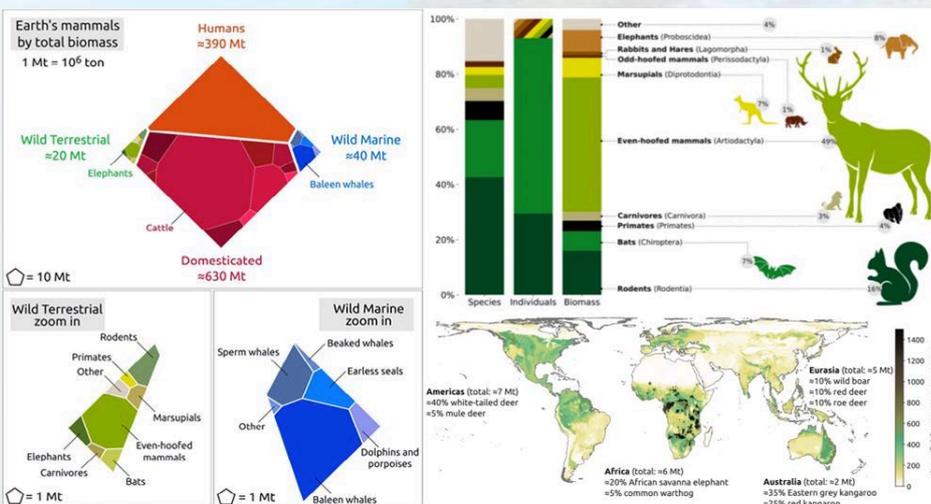

Fig 19c: **Left Top:** The global mammalian biomass distribution is dominated by humans and domesticated mammals, including livestock and pets. **Bottom:** enlarged view of the biomass of wild terrestrial (Left, grouped by order) and marine mammals (Right, grouped by family, or few families). **Top right:** The relative number of species, individuals, and total biomass of each taxonomic order of wild land mammals. The relative biomass contribution of each order is also indicated by the animal silhouette sizes and corresponding percentages.

Lower right: The estimated total biomass is noted for each continent, together with the name of the top mass contributor and its relative biomass contribution to the said continent.

¹⁶ In Greek mythology, Gaia from Ancient Greek Γαῖα, a poetical form of Γῆ Gē, "land" or "earth"), also spelled Gaea is the personification of the Earth and one of the Greek primordial deities. Gaia is the ancestral mother – sometimes parthenogenic – of all life.

The team led by Ron Milo has updated the biomass of world mammals. Biomass as a metric allows us to compare species with very different body sizes, and can serve as an indicator of wild mammal presence, trends, and impacts, on a global scale. Here, we compiled estimates of the total abundance (i.e., the number of individuals) of several hundred mammal species from the available data, and used these to build a model that infers the total biomass of terrestrial mammal species for which the global abundance is unknown. We present a total wet biomass of ≈20 million tonnes (Mt) for all terrestrial wild mammals (95% CI 13-38 Mt), i.e., ≈3 kg per person on earth.

The universe as we know it has been in existence for some 13 billion years, but for over around a quarter of this cosmic lifetime, around 3.6 billion years, life in all its variety and complexity has continued to evolve to the point of human emergence, amid climax biological diversity, having taken some 66 million years to recover from the mass extinction caused by the Chicxulub asteroid that extinguished the dinosaurs. Our impact is rapidly becoming worse and setting us for a global heating, taking us back 50 million years to the Eocene peak (and yet we remain unable to give the priority to correct it due to our own folly. More troubling, it runs the risk of a Permian type extinction, the most catastrophic mass extinction of multicellular life ever, which like our own climate crisis, was caused by extreme global warming.

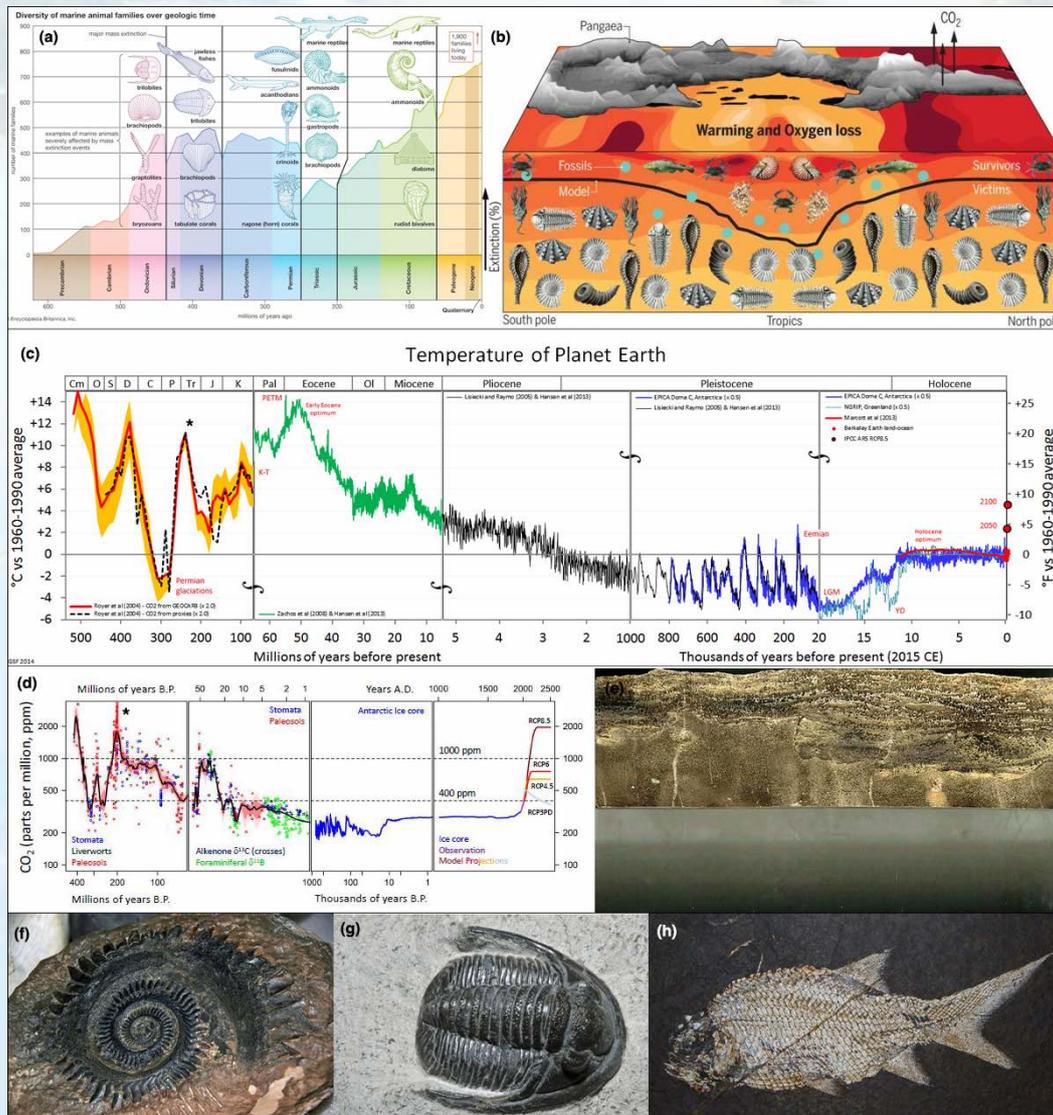

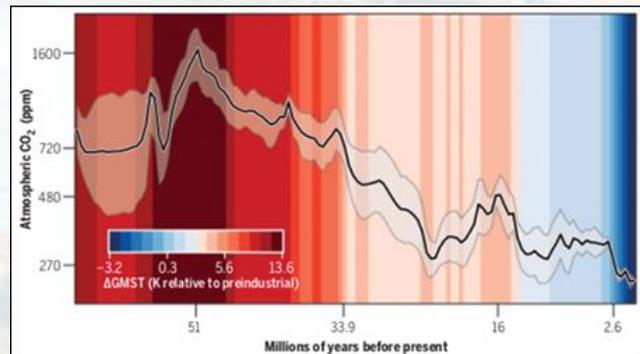

Fig 20: (a) The five mass extinctions dominated by the Permian, in which up to 95% of marine fauna expired. (b) The Permian was not caused by an incoming asteroid but a huge peak in atmospheric CO₂, precipitated by massive eruptions which resulted in the Siberian Traps. The eruptions continued for roughly two million years and spanned the Permian–Triassic boundary, around 251.9 million years ago. (b, c) Historic temperatures and atmospheric CO₂ since the Cambrian, 500 million years ago both show a massive peak at the boundary (marked * in (c) and (d)) (Mulhern 2021). This resulted in the oceans becoming depleted in oxygen, making them oceans uninhabitable particularly to more temperate species, likely exacerbated by lethal H₂S contamination. (e) A 1.5-foot slab of rock from southern China shows the Permian-Triassic boundary. The bottom section is pre-extinction limestone. The upper section is microbial limestone deposited after the extinction. Three species that became extinct. (f) A fossilised spiralling shark tooth from *Helicoprion*, an extinct Permian shark species. (g) *Diademaproetus*, one of the trilobites that were plentiful in the world’s oceans but went extinct at the end of the Permian. (h) *Paramblypterus*, a species of fish that became extinct during the Permian.

During the end-Permian (P-T) extinction, 95 percent of all species on Earth became extinct, compared to only 75 percent during the Cretaceous-Tertiary (K-T) extinction, when a large asteroid impact, possibly exacerbated by ensuing volcanic activity, caused the dinosaurs to disappear. The impact of *Homo sapiens* on our planet is a striking example of how life can evolve to evoke existential crisis on a planetary scale, threatening both a mass extinction of living diversity by habitat destruction, runaway global heating from fossil fuel consumption and a possible nuclear holocaust, but there are others. Severe global heating can lead to the oceans becoming anoxic, resulting in oceanic bacteria using sulphate to poison the oceans and atmosphere with hydrogen sulphide.

We are used to the idea of the Gaia Hypothesis – that life is an integral part of a self-correcting global biochemical and geochemical process that keeps Earth conducive and habitable for life provided critical tipping points are not transgressed, to push this system beyond a point of no return. But what happens if things go too far? There is a known counterpoint to Gaia, and that is the Medea Hypothesis (Ward 2008) that under certain circumstances, living systems can also precipitate biochemical and geochemical feedback process that can bring about the mass extinction of life, like a mother killing her children.

Fig 20a: Levels of CO₂ over the last 50 mya (compare fig 19(2)) compared with global mean surface temperature (inset and colour bands (Hönisch et al. 2023).

The central cause of the Permian extinction is temperature-dependent hypoxia (Penn et al. 2018):

The conventional wisdom in the paleontological community has been that the Permian extinction was especially severe in tropical waters.” Yet the model shows the hardest hit were organisms most sensitive to oxygen found far from the tropics. Many species that lived in the tropics also went extinct in the model, but it predicts that high-latitude species, especially those with high oxygen demands, were nearly completely wiped out (study co-author Jonathan Payne).

Since tropical organisms’ metabolisms were already adapted to fairly warm, lower-oxygen conditions, they could move away from the tropics and find the same conditions somewhere else,” Deutsch said. “But if an organism was adapted for a cold, oxygen-rich environment, then those conditions ceased to exist in the shallow oceans (study co-author Curtis Deutsch).

The huge igneous layers of the Siberian Traps (about 7 million km² (3 million sq mi) of basaltic rock, with a volume of around 4 million km³ (1 million cu mi) were formed by flood basalt volcanism from a mantle plume, as in Iceland and Hawaii which rose until it impacted against the bottom of the Earth's crust pouring from great cracks in the land itself. As the magma rushed out into the air from its deep Earth origin, it carried enormous volumes of volcanic gas into the atmosphere, including hydrogen sulphide, methane and particularly carbon dioxide. If flood basalts are combined on a global scale with the more explosive volcanism that in addition, throws great quantities of ash and volcanic dust into the atmosphere, one might expect major effects on animals and plants.

Although the global heating caused by the erupted CO₂ would not necessarily be enough on its own to cause a mass extinction of this scale, it could have set off a diabolical series of events that led to mass extinction. The warmer the tropical oceans the more the animal oxygen consumption. Normally, the deep ocean gets its oxygen from the atmosphere at the poles. Cold water there soaks up oxygen from the air and because cold water is dense, it sinks and slowly moves equator-ward, taking oxygen with it. The warmer the water, the less oxygen can dissolve and the slower the water sinks and moves toward the equator. The resulting atmospheric warming would in turn, warm surface ocean water enough to cause oceanic oxygen starvation by disrupting this conveyor belt flow, thus bringing less oxygen into the deep oceans. Once the oxygen is gone, the oceans become the realm of oceanic bacteria that obtain their oxygen stripping oxygen from sulphur oxide compounds such as sulphate, producing hydrogen sulphide, which kills aerobic organisms, as well as destroying the ozone layer protecting terrestrial plants. Methane produced in the ample swamps of this time period then has little to destroy it, so the atmosphere becomes laden with hydrogen sulphide, methane and ultra-violet radiation (Ward 2007, 2008). This scenario has been applied both to the Permian and succeeding Triassic-Jurassic (T-J) extinction (Kump, Pavlov & Arthur 2005, Richoz et al. (2012).

CO₂ levels are determined by the imbalance between carbon sequestration (burial in sediments, capture by plants), and carbon emissions (decomposition and volcanic activity). Imbalances in this system created a downward trend in CO₂ levels, leading to a glaciation period around 300 million years ago. This was followed by a period of intense volcanic activity, doubling CO₂ concentration

to about 1000 ppm. Levels then dropped until they reached today's concentrations during the [peak Eocene to] Oligocene era, 33 to 23 million years ago, when temperatures were still 4 to 6 degrees C higher than today. It can be said that history was shaped by CO₂ levels, and the types of climates they would allow. Looking back at the 2 extra degrees of warmth last time CO₂ levels were this high (Pliocene era, 3 million years ago), should be enough of a call to action, considering the damage two more degrees would cause today. (Mulhern 2021).

Under a business-as-usual emissions scenarios, by 2100 warming in the upper ocean will have approached 20 percent of warming in the late Permian, and by the year 2300 it will reach between 35 and 50 percent. This study (Penn et al. 2018) highlights the potential for a mass extinction arising from a similar mechanism under anthropogenic climate change (Justin Penn).

Global strategies to Halt the Dual Crises of Biodiversity loss and Climate Change

These are often formulated separately, even though they are interdependent and risk failure if pursued in isolation. The Global Safety Net maps (Dinerstein et al. 2022) show how expanded nature conservation addresses both overarching threats. We identify 50% of the terrestrial realm that, if conserved, would reverse further biodiversity loss, prevent CO₂ emissions from land conversion, and enhance natural carbon removal. This framework shows that, beyond the 15.1% land area currently protected, 35.3% of land area is needed to conserve additional sites of particular importance for biodiversity and stabilize the climate. Fifty ecoregions and 20 countries contribute disproportionately to proposed targets. Indigenous lands overlap extensively with the Global Safety Net. Conserving the Global Safety Net could support public health by reducing the potential for zoonotic diseases like COVID-19 from emerging in the future.

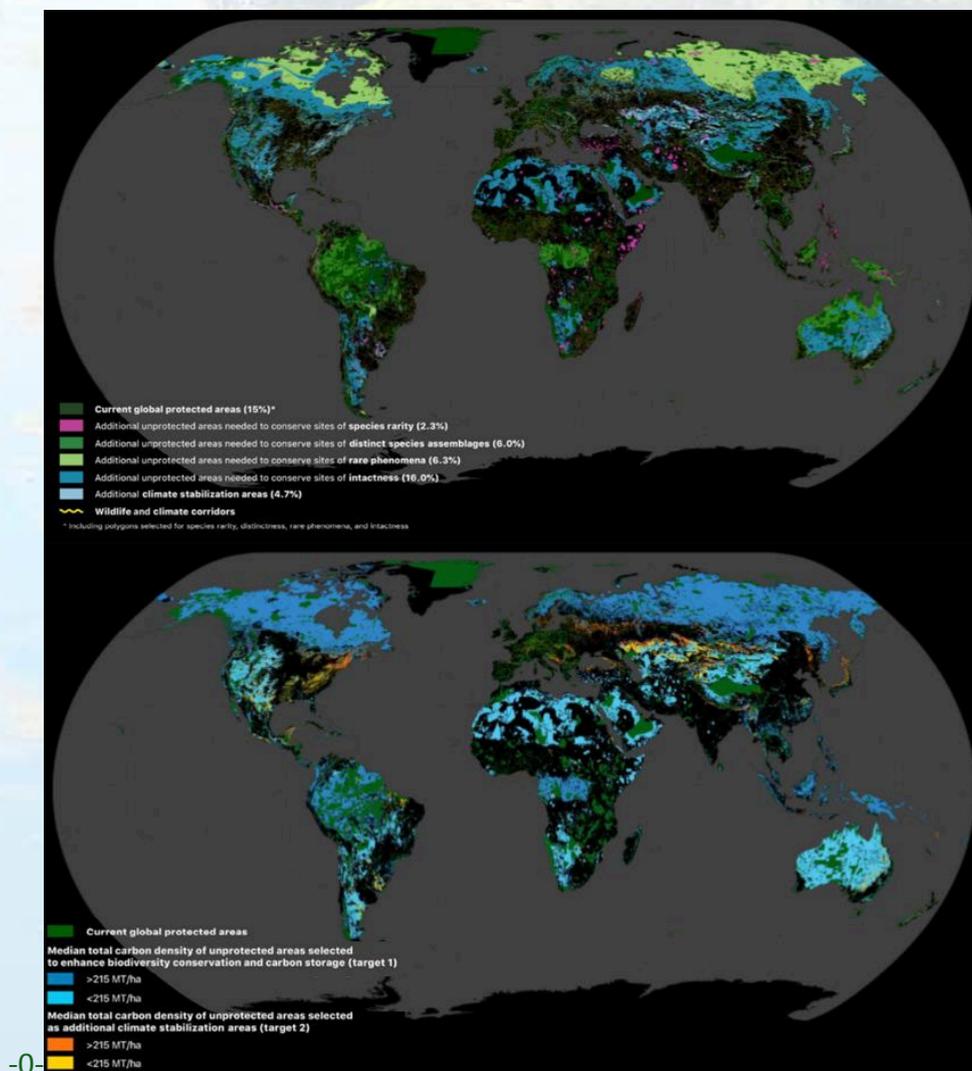

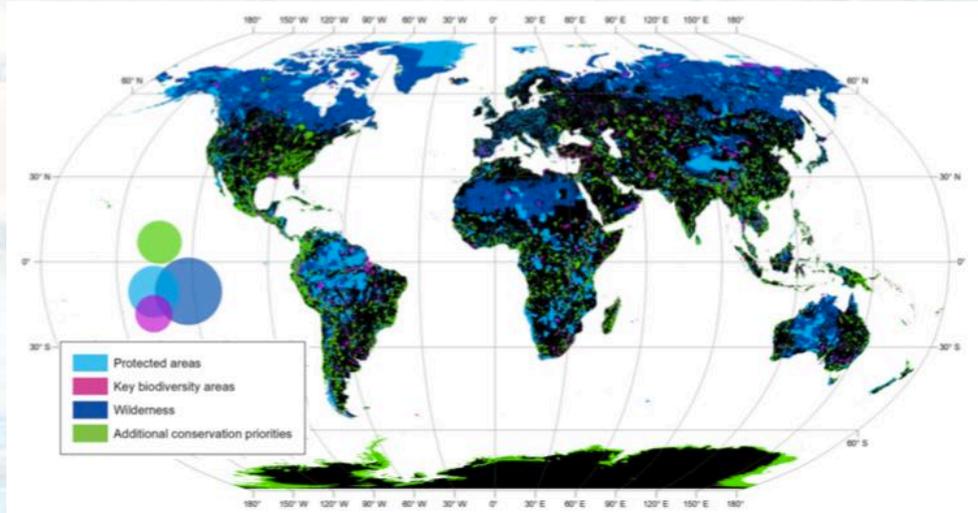

Fig 20b: (Top) Areas of the terrestrial realm where increased conservation action is needed to protect biodiversity and store carbon. Numbers in parentheses show the percentage of total land area of Earth contributed by each set of layers. (Bottom) Interdependence of carbon and biodiversity. Currently unprotected high-carbon areas with median total carbon >215 MT/ha overlap extensively (92.0%) with areas selected under target 1, highlighting the importance of these lands for biodiversity conservation and climate stabilization. Other areas important for biodiversity but of lower carbon value, i.e., <215 MT/ha, are also shown. Additional CSAs, including tier 1 and tier 2 CSAs, are also selected to bridge the gap for adequate carbon storage beyond areas identified in target 1 (Dinerstein et al. 2022).

The minimum land area requiring conservation attention to safeguard biodiversity

Fig 21: Minimum land area for conserving terrestrial biodiversity. Components include PAs (light blue), KBAs (purple), and ecologically intact areas (dark blue). Where they overlap, PAs are shown above KBAs, which are shown above ecologically intact areas. New conservation priorities are in green. The Venn diagram shows the proportional overlap between features (Allan et al. 2022).

Ambitious conservation efforts are needed to stop the global biodiversity crisis (Allan et al. 2022). We estimate the minimum land area to secure important biodiversity areas, ecologically intact areas, and optimal locations for representation of species ranges and ecoregions. At least 64 million square kilometers (44% of terrestrial area) would require conservation attention (ranging from protected areas to land-use policies) to meet this goal.

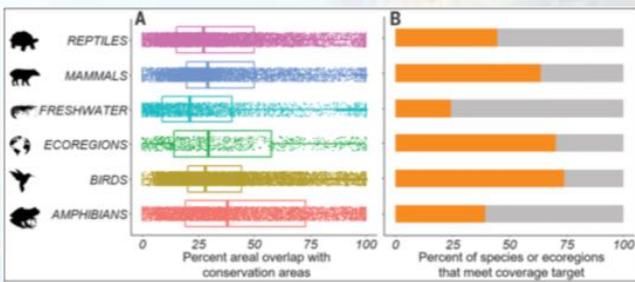

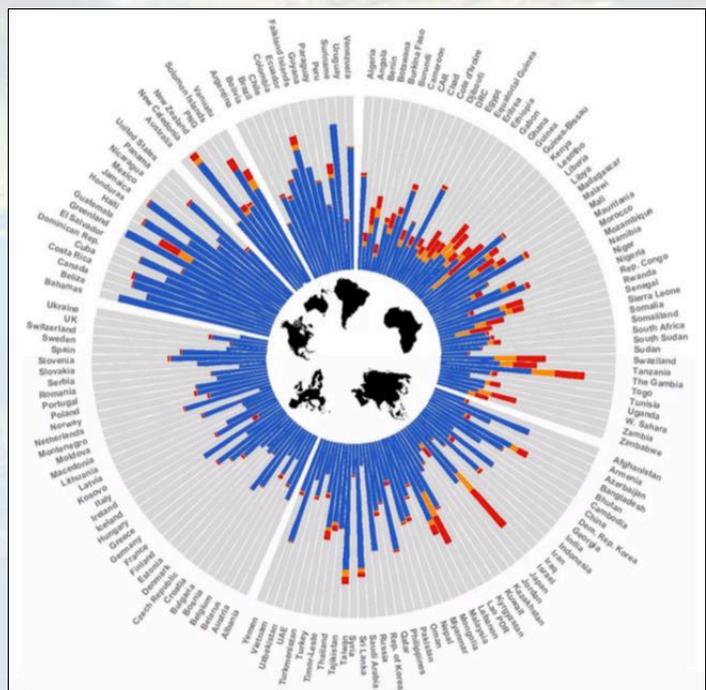

Fig 22: Gap analyses of species and ecoregion coverage within areas above. (A) Percentage of the distribution of each species (in different taxonomic groups; freshwater includes crabs, shrimp, and crayfish) and ecoregion area that overlaps. Boxplots show the median and 25th and 75th percentiles. (B) Percentage of species and ecoregions with an adequate proportion of their distribution overlapping existing conservation areas to meet specific coverage targets for species or ecoregions (orange).

responses that promote autonomy, self-determination, equity, and sustainable management for safeguarding biodiversity are essential. Spatially explicit land-use scenarios suggest that 1.3 million square kilometers of this land is at risk of being converted for intensive human land uses by 2030, which requires immediate attention. However, a sevenfold difference exists between the amount of habitat converted in optimistic and pessimistic land-use scenarios, highlighting an opportunity to avert this crisis. Appropriate targets in the Post-2020 Global Biodiversity Framework to encourage conservation of the identified land would contribute substantially to safeguarding biodiversity.

Fig 23 National-level land area for conservation and projected habitat loss. Estimated proportion of each country requiring effective conservation attention to safeguard biodiversity that is projected to suffer habitat conversion by 2030 (orange) and 2050 (red) or that is projected not to be converted (blue), according to SSP3 (a worst-case scenario). Gray areas are outside the land identified for conservation. We excluded 85 countries with a land area <10,000 km² from the figure (Allan et al. 2022).

More than 1.8 billion people live on these lands, so

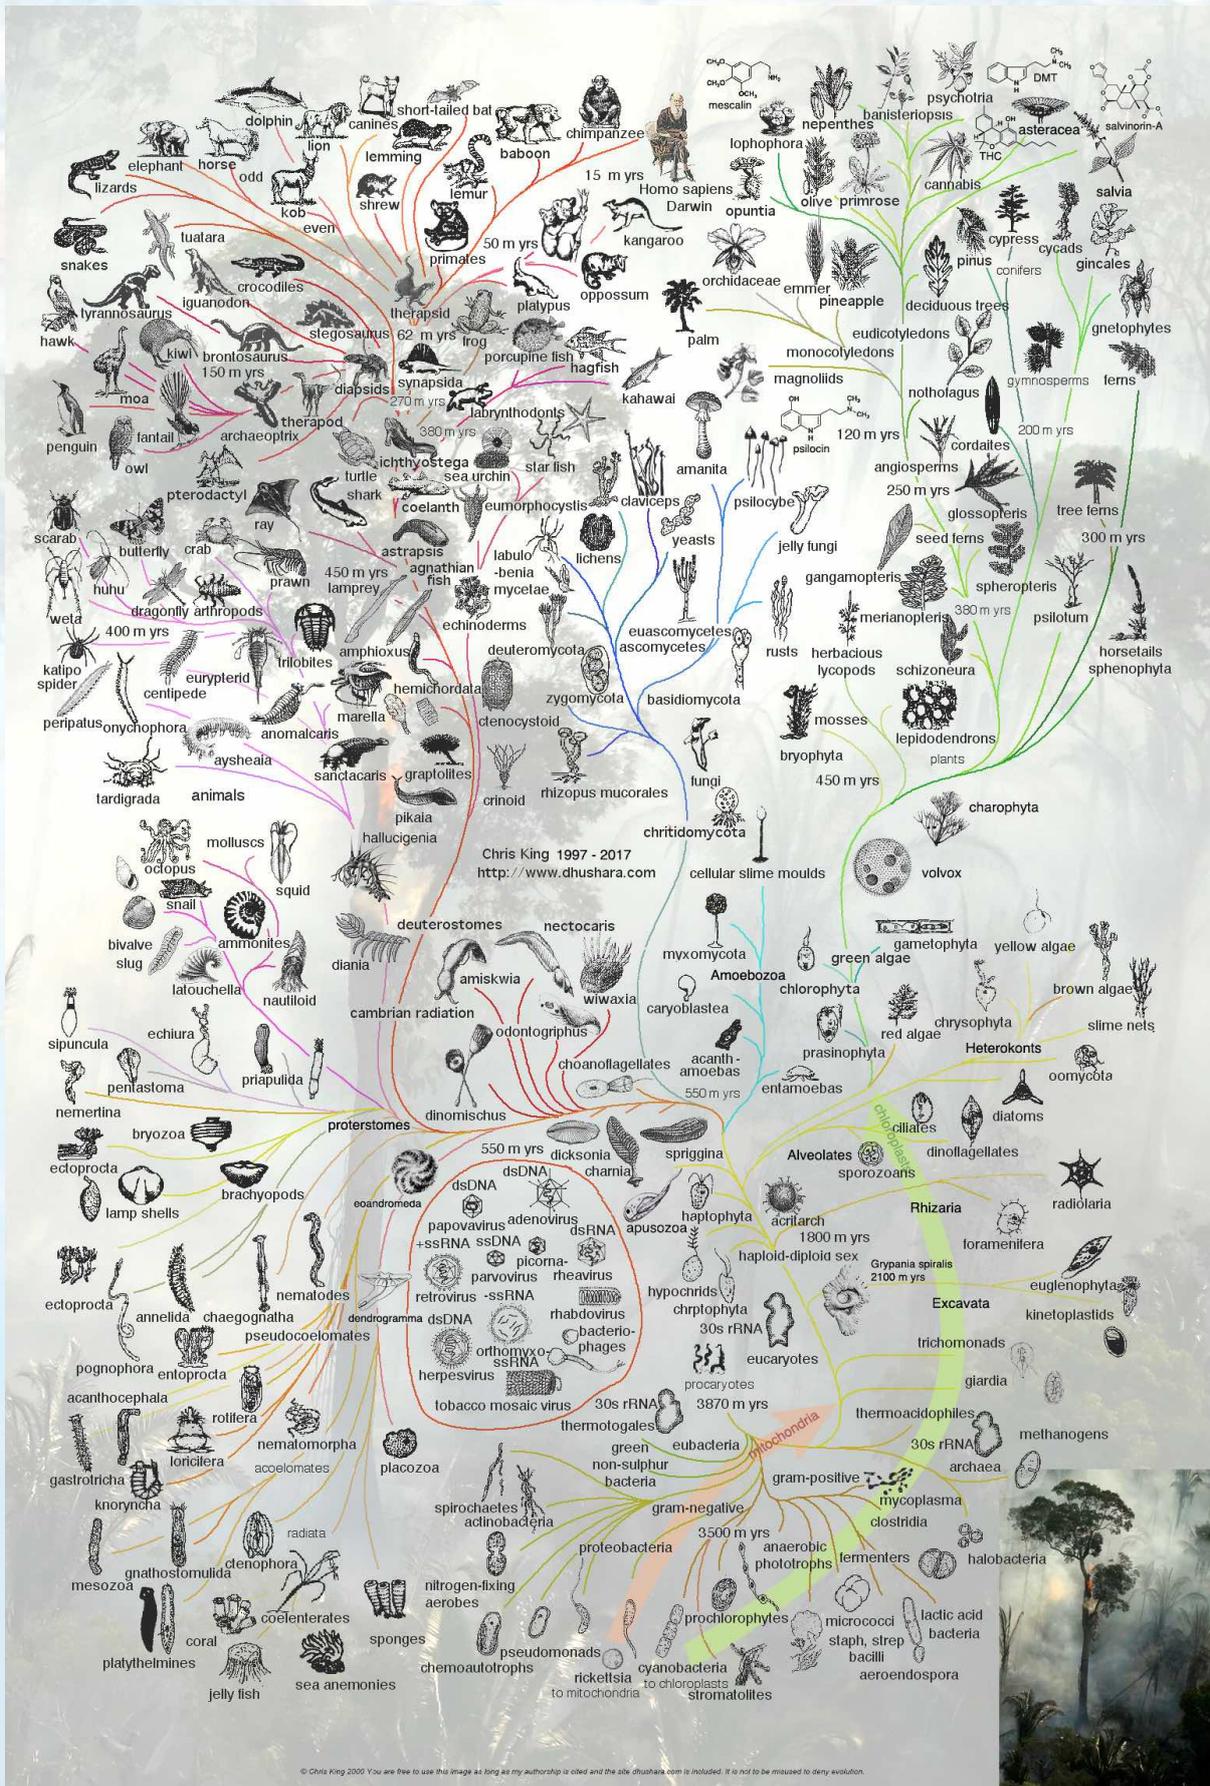

Fig 24: Evolutionary tree of life (King 2021c), with entheogenic molecules. Preserving the diversity of life and of conscious life in evolutionary time scales is the prime responsibility of our sentient incarnation. Background: Amazon burning.

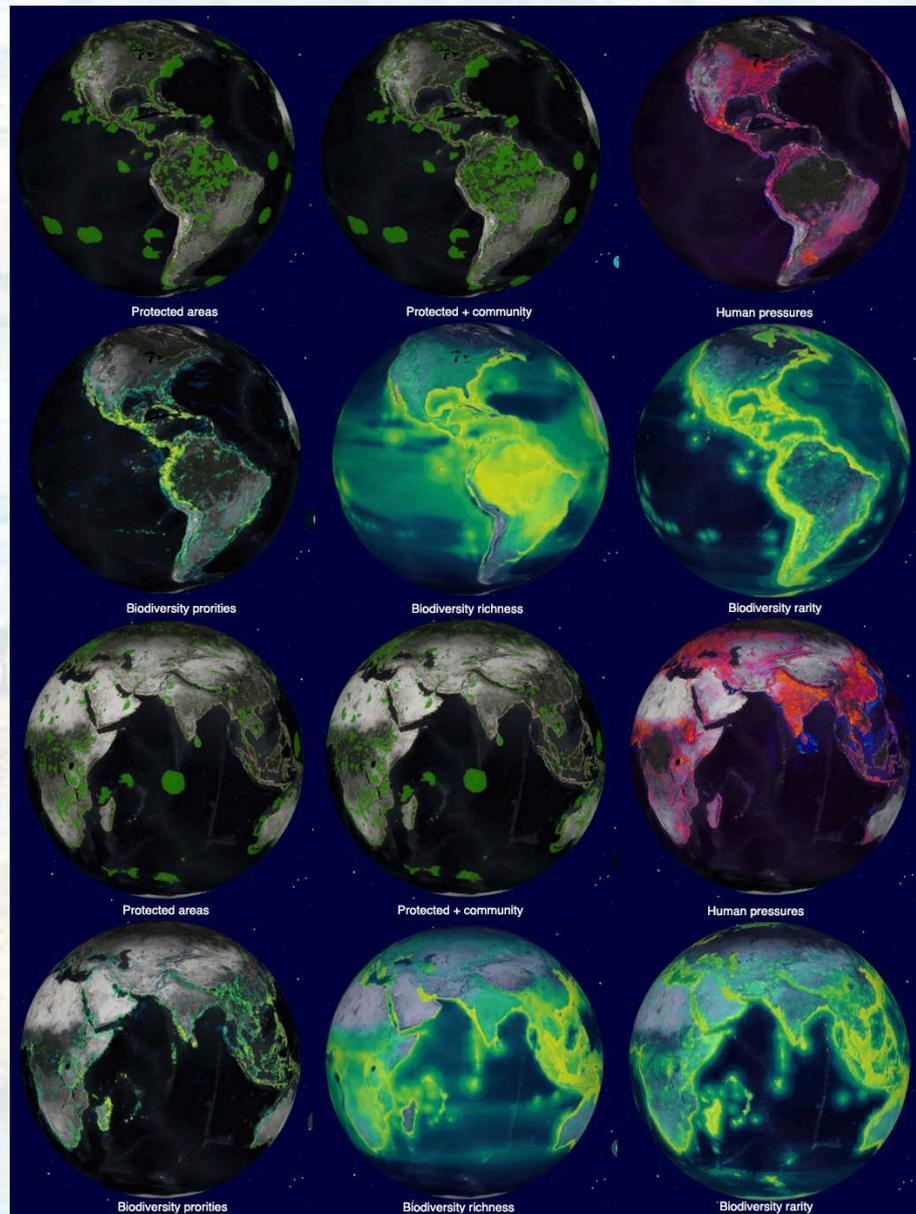

Fig 25: Scenario maps Half Earth Project show (1) protected areas, (2) protected+community, (3) human pressures (4) biodiversity priority, (5) biodiversity richness and (6) biodiversity rarity. These show the difficulty of planning for a half-Earth scenario because some countries have high value habitats which urgently need conserving while others lack any significant protected areas. Furthermore protected areas are not identical with the biodiversity priorities. Habitats involving priority species and rare species are quite distinct from areas with the greatest richness (Rinnan & Jetz 2020). This means that protecting half Earth is going to require massive funding of some developing countries and wide scale consent and economic motivation on the part of developed countries to resolve these questions. The science is critical to make the process as effective as possible but this is also going to take a huge change in the human world view to upgrade its urgency sufficiently.

If you look at the Amazon Basin it looks as though there is little overlap between biodiversity richness and human pressure, but we know that's not true because the Amazon is being ravaged by fire, mining and agriculture. Moreover The priorities for biodiversity also lie, prominently lie along the Andes, with high overlap with human impact.

Turn now to Africa and you will see a big conflict between human pressure and biodiversity priorities in the North East Congo and south to the Cape of Good Hope. This means that stopping a serious mass extinction is going to have to involve a new kind of global planning and financing to compensate affected parties and to ensure consistent standards of protection and mitigation. Predictions of biodiversity at 2100 remain contradictory depending on how the driving factors interact (Sala et al. 2000). Wilderness areas halve the extinction risk of terrestrial biodiversity (Di Marco 2019).

Davis et al. (2018) note that the incipient sixth mass extinction that started in the Late Pleistocene has already erased over 300 mammal species and, with them, more than 2.5 billion y of unique evolutionary history. At the global scale, this lost phylogenetic diversity (PD) can only be restored with time as lineages evolve and create new evolutionary history. Given the increasing rate of extinctions however, can mammals evolve fast enough to recover their lost PD on a human time scale? We use a birth–death tree framework to show that even if extinction rates slow to pre-anthropogenic background levels, recovery of lost PD will likely take millions of years.

This is going to take a paradigm shift in world views to get anywhere in time. It needs to convey an urgency and a sense of cosmological meaning to support the undertaking both scientifically and religiously to actually get there. There has to be some sheer inspiration and conviction to do this.

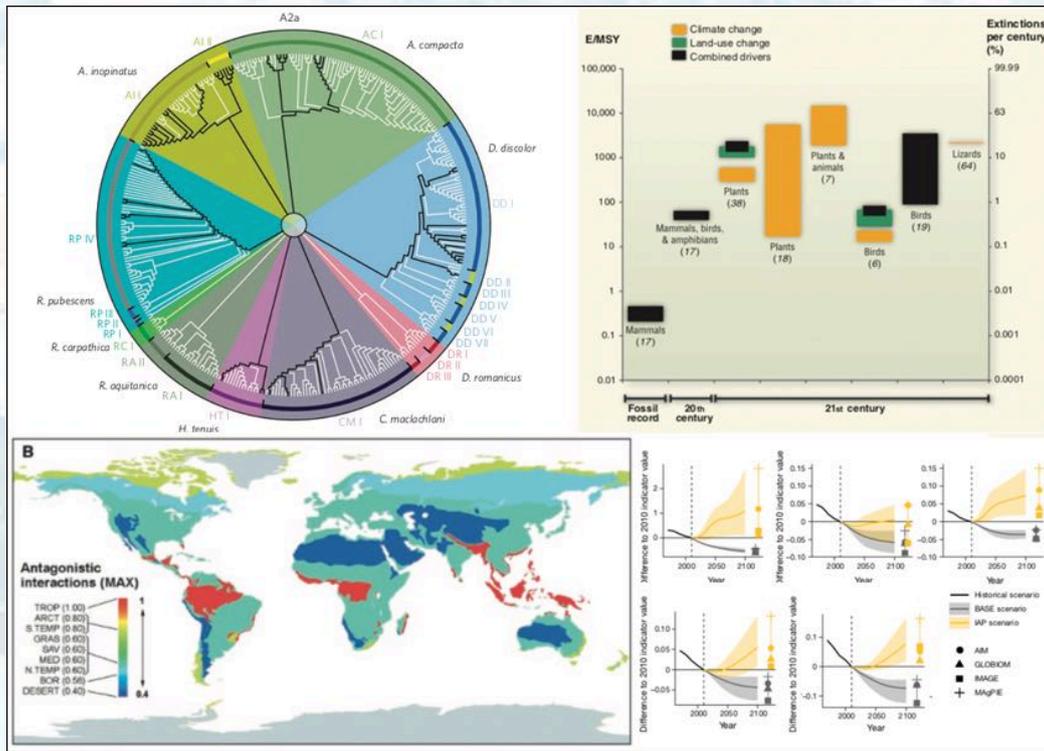

Fig 26: Top left: Predicted loss of mitochondrial cytochrome c oxidase subunit I haplotypes for nine montane aquatic insect species in Europe under business as usual IPCC 2080 CO₂ emission scenario (Bálint et al. 2011). Top right: Comparison of recent and distant past extinction rates with rates at which species are “committed to extinction” during the 21st century (Pereira et al. 2010). Bottom left: Map of expected change in biodiversity for the year 2100 under antagonistic interaction between drivers such as climate and habitat loss when the total biodiversity change equals the change resulting from the driver that is expected to have the largest effect and is calculated as the maximum of the effects of all the drivers (Sala et al. 2000). All of the key tropical rainforest would be seriously affected. Bottom right: Estimated recent and future global biodiversity trends resulting from land-use change, with and without coordinated efforts to reverse trends (Leclère et al. 2020). Habitat effects on their own contribute up to 20% loss in diversity (grey) unless adequate measures are taken (ochre). Mean extinction probability across studies making predictions of the future effects of climate change suggest a mean extinction probability of 10% across taxa and regions, whereas empirical evidence gave a mean probability of 14% (MacLean et al. 2011).

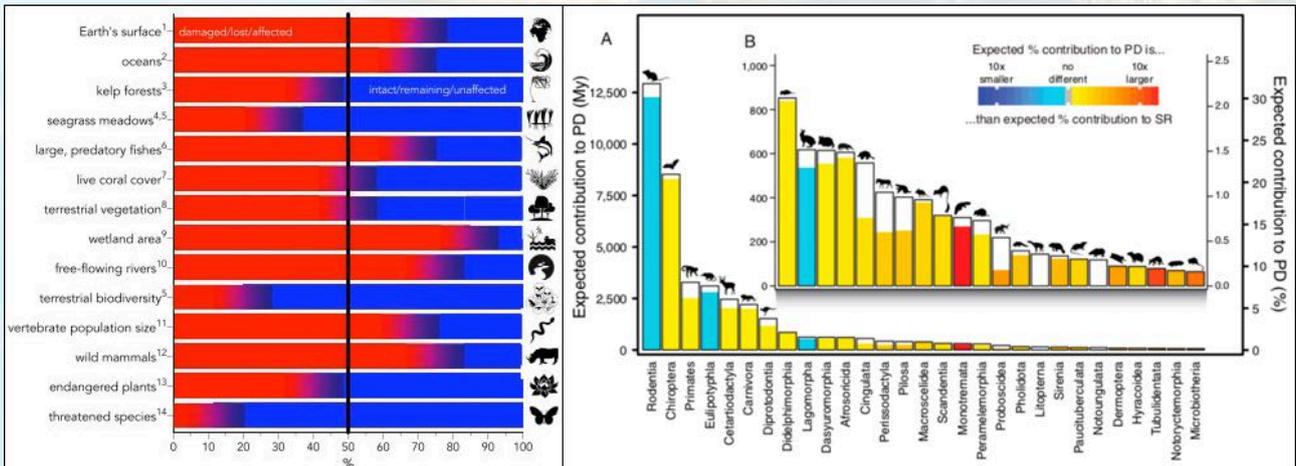

Fig 27: Left: Summary of major environmental-change categories expressed as a percentage change relative to the baseline given in the text. Red indicates the percentage of the category that is damaged, lost, or otherwise affected, whereas blue indicates the percentage that is intact, remaining, or otherwise unaffected (Bradshaw et al. 2021). Right: Loss of evolutionary history is variable across mammalian orders. The heights of the bars show the amount of unique evolutionary history attributable to each mammalian order at a preanthropogenic baseline (130,000 y ago). The right-hand y axis shows this same value as a percentage of global mammal PD at this baseline. The heights of the colored bars show the contribution to global PD projected to remain after 50 y of status quo conservation. Warm colors represent proportional contributions that are high for an order’s SR; cool colors show the reverse. The orders Didelphimorpha to Microbiotheria are shown at standard (A) and enlarged (B) scales (Davis et al. 2018).

Human impact is causing a mass extinction of biodiversity on a time scale that is almost as acute in terms of the adaption of life as the Dinosaur extinction and is rapidly approaching a series of tipping points that could throw the

entire planet into a far less hospitable state, not just for the diversity of life but for our own survival. As the Earth heats due to CO₂ and methane emissions, the albedo¹⁷ of the white, light-reflecting poles shrinks, so that it absorbs more light increasing the heating. Destabilising the methane hydrates on the ocean floor can lead to a world-wide eruption of CH₄ which is 20 times more active in solar heating than CO₂. At the same time the entire forested areas of the planet that fix carbon are being replaced by pasture and agriculture, compounded by massive fires both lit intentionally to clear forest and arising naturally from lightning strikes due to increased heat and the drying out of forest areas.

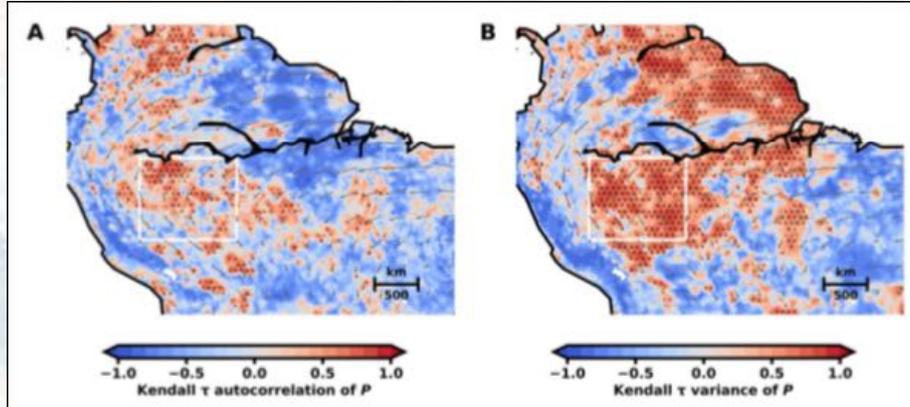

Fig 27b: Statistical early-warning signals that the Amazon monsoon is approaching a critical transition in response to deforestation and could continue to fail due to deforestation, resulting in cumulative desiccation. Large parts of southwestern Amazonia show a simultaneous increase in variance and autocorrelation. Regions with high autocorrelation correspond well with the main atmospheric moisture transport routes and the aerial river across the Amazon to the subtropics (Bochow & Boers 2023).

As I was writing this section on Boxing Day 2021, E O Wilson regarded as Darwin's heir passed away. Here are three statements he made about Biodiversity in interview about his book "The Meaning of Human Existence":

We are by instinct related closely to the survival of our distant ancestors by a driving need to strike nature as hard as we could, and to draw as much as we could from it. And we haven't lost that at all. And now we come to a higher-level recognition that we struck too hard, and too far, and we are threatening the world that we first entered so aggressively and successfully in Africa. And we somehow have got to pull back our instincts to exploit and subordinate and convert to our immediate welfare—because if we take too much more of the Earth's biodiversity we render the biosphere unstable. And we could, in the worst of circumstances, reach a tipping point in which the whole thing collapses—and we with it.

The living world the biosphere is a razor thin layer of organisms that have evolved over billions of years to create close to exactly the right combination of species and their interactions to maintain the conditions that they live in. Our minds and our bodies are particularly well designed by natural selection to live in those exact conditions and if we change it in any significant way, we die quickly, and so we should keep in mind that, when we destroy the living world by allowing species to go extinct, you're weakening the biosphere and eventually, you may reach a tipping point in which the whole thing starts to unravel, and when that happens pfutttt the end of everything.

Part of our problem is that we're a species that is narcissistic. We're intensely social and intensely interested in other people and that's how we keep our groups united and well coordinated. The result is that we're geniuses at social intelligence and really stupid when it comes to understanding how to manage the environment. We are a badly adapted species right now. We have created civilisations in which we lead and live on parts of the planet on our own. And we haven't gotten over our emphasis on forming groups and having groups compete with each other. IT's easy for us to think that the world was made for us and we don't really need to know about the 8 million or so species on this planet, even when we're told that keeping them intact and making sure they continue to live is probably necessary for our long-term existence.

The [Covid-19 pandemic](#) has shown us a world which cannot realistically modify business as usual exploitation to address the human impact on the biosphere that precipitated the pandemic through trafficking and exploitation of wild animals. This inability risks a potentially irreversible planetary tipping point. The fact that we can even temporarily be stopped in our tracks by a mere virus underscores the vulnerability of the human population to misadventure and the fragility of technological civilisation. By comparison with dealing with a pandemic, the cumulative problems of human impact are far more deleterious to both future quality of life and to the world's economic viability, and could result in the mortality of billions of people. The problems are made all the more intractable because action requires international cooperation to transform our energy and consumption economies,

¹⁷ *Albedo* is a quantity that indicates how well a surface reflects solar energy. ... the "whiteness" of a surface, with 0 meaning black and 1 meaning white. A value of 0 means the surface is a "perfect absorber" that absorbs all incoming energy.

but this is mired by national and political interests and resolute will can be unravelled all too easily by a single populist defector in a position of power, disrupting the capacity of the world to act cogently and scientifically.

Underlying the climate crisis is a much more serious and potentially devastating one for humanity's future quality of life, economic future and survival as a species, and that is the mass extinction (Leakey & Lewin 1996) of biodiversity, driven both by whiplash climate change and wholesale habitat destruction further exacerbated by deforestation and the burning of both the tropical rainforests and temperate forests of Earth, as well as the conversion of vast wilderness areas to monoculture. Whole geographical regions of the planet, both at cooler poles where temperatures changes are magnified and in the hotter drier tropics are likely to devastate their plant and animal diversity. The issues of biocrisis (King 2006-2020) and mass extinction are more serious than climate change or human induced pandemics and require a combined strategy of mitigation of habitat destruction, replanting of wilderness areas, conversion of food production and consumption to less polluting and carbon-intensive practices and collecting as much genetic diversity as possible in gene banks to conserve plant, bacterial, and fungal diversity. The fate of insects and other small multi-celled animals is also highly important for overall planetary fertility, as exemplified from honey bees to humming birds.

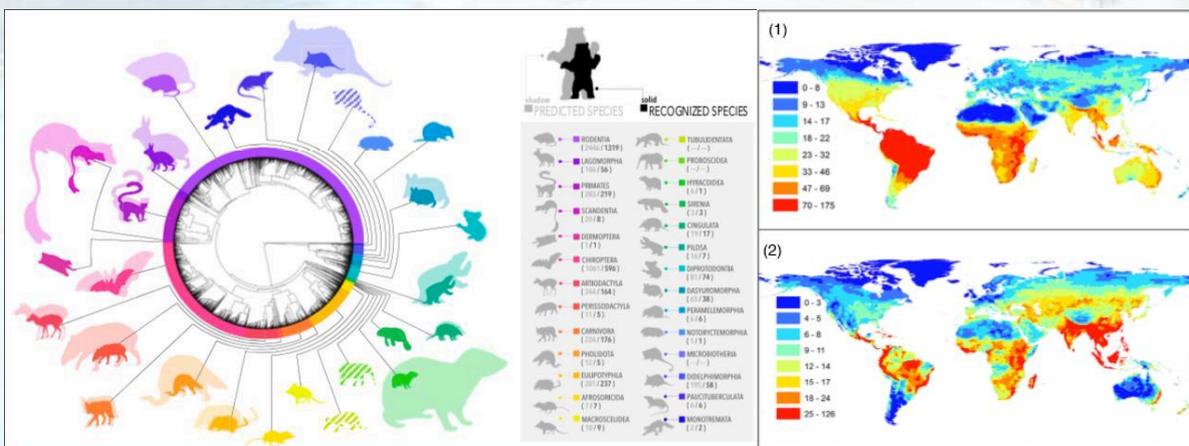

Fig 28: (Left) Phylogenetic distribution of hidden mammalian diversity estimated from consensus of delimitation results. Each silhouette represents a mammalian order with its shadow reflecting the ratio of predicted species to recognised species. Striped silhouettes represent orders with conflicting delimitation results that were not included in the predictive analysis (Parsons et al. 2022). The uncertainties may be much larger in other groups e.g. arthropods. (Right) Mutilation of the animal tree of life: (1) Monotypic genera (2) Endangered genera (Ceballos & Erlich 2023)

(a) **Half Earth** The biosphere needs immediate protection from human impact over a full half its surface and restoration by a clear dedicated program (Wilson 2016, Le Page 2018, Baillie & Zhang 2018, Dinerstein et al. 2019, Lambert 2020, Convention on Biological Diversity), and assisting diversity to replenish in the wilderness is essential for the long-term robustness of the biosphere's diversity and of human species over evolutionary time scales. Although we are stripping the biosphere, we are very small on the face of the planet and dependent on stable food supplies. Planetary changes crossing tipping points, would have a much more serious long term impact on the viability of human species, let alone the economy, than by adopting the precautionary principle. Climate change remains a serious long term risk to biodiversity and the human population. Changes in the ocean level, once initiated will continue for up to 1000 years due to changes in the planetary albedo as the white polar caps melt. They could render vast land areas uninhabitable to humans and for food production reducing the economic carrying capacity of the planet for human life for millennia to come, with increasing desertification in some areas and flooding in others all impacting on biodiversity. Pollution, from estrogenic chemicals to ocean plastics, also needs urgent containment.

(b) **Nuclear Holocaust** We remain in a situation of mutually-assured destruction due to a massive overkill of nuclear destructive power, which could also lead to a human and biodiversity genocide. This remains a key challenge and a dark comment on the patriarchal male-combat winner-take-all death-risking reproductive strategy, extrapolated to utopian proportions, which urgently needs to be addressed for the safety of the human species and the biosphere. This is human maleficence being appropriated to create a hair-trigger potential for mass destruction, rather than using this technology to avoid astronomical threats to biospheric survival. All sides are drawn into a Faustian pact, in which no one can agree to unwind the false security that the unilateral exercise of nuclear deterrent continues to have, leading to inexorable cumulative long-term risks of species extinction by accidental or malicious global holocaust.

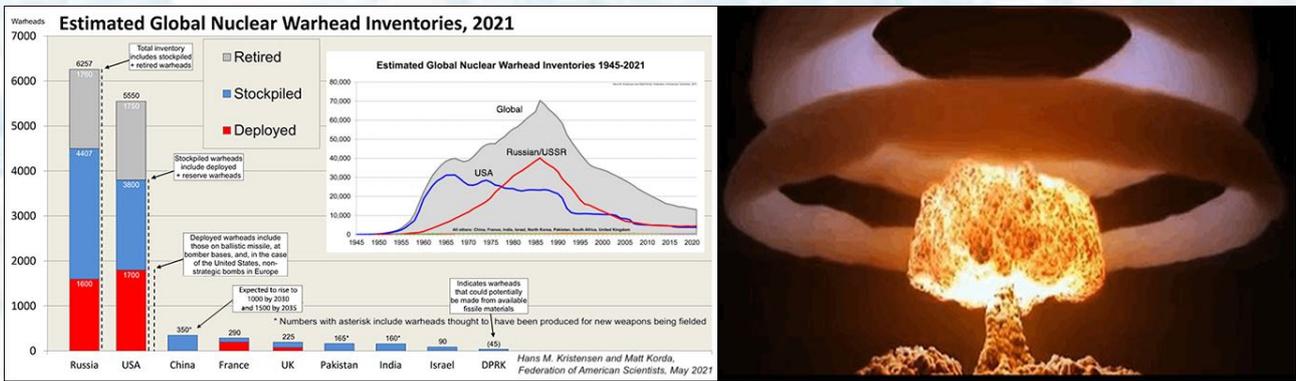

Fig 29: Left: Current state of world nuclear weapon stockpiles. Right: Tsar bomba 50 megatons [video](#). Black rose [video](#).

The Federation of American Scientists notes: *“Despite progress in reducing Cold War nuclear arsenals, the world’s combined inventory of nuclear warheads remains at a very high level: roughly 13,100 warheads as of early-2021. Of these, nearly 9,600 are in the military stockpiles (the rest are awaiting dismantlement), of which some 3,800 warheads are deployed with operational forces, of which up to 2,000 US, Russian, British and French warheads are on high alert, ready for use on short notice. ... All the nuclear weapon states continue to modernise their remaining nuclear forces, adding new types, increasing the role they serve, and appear committed to retaining nuclear weapons for the indefinite future”.*

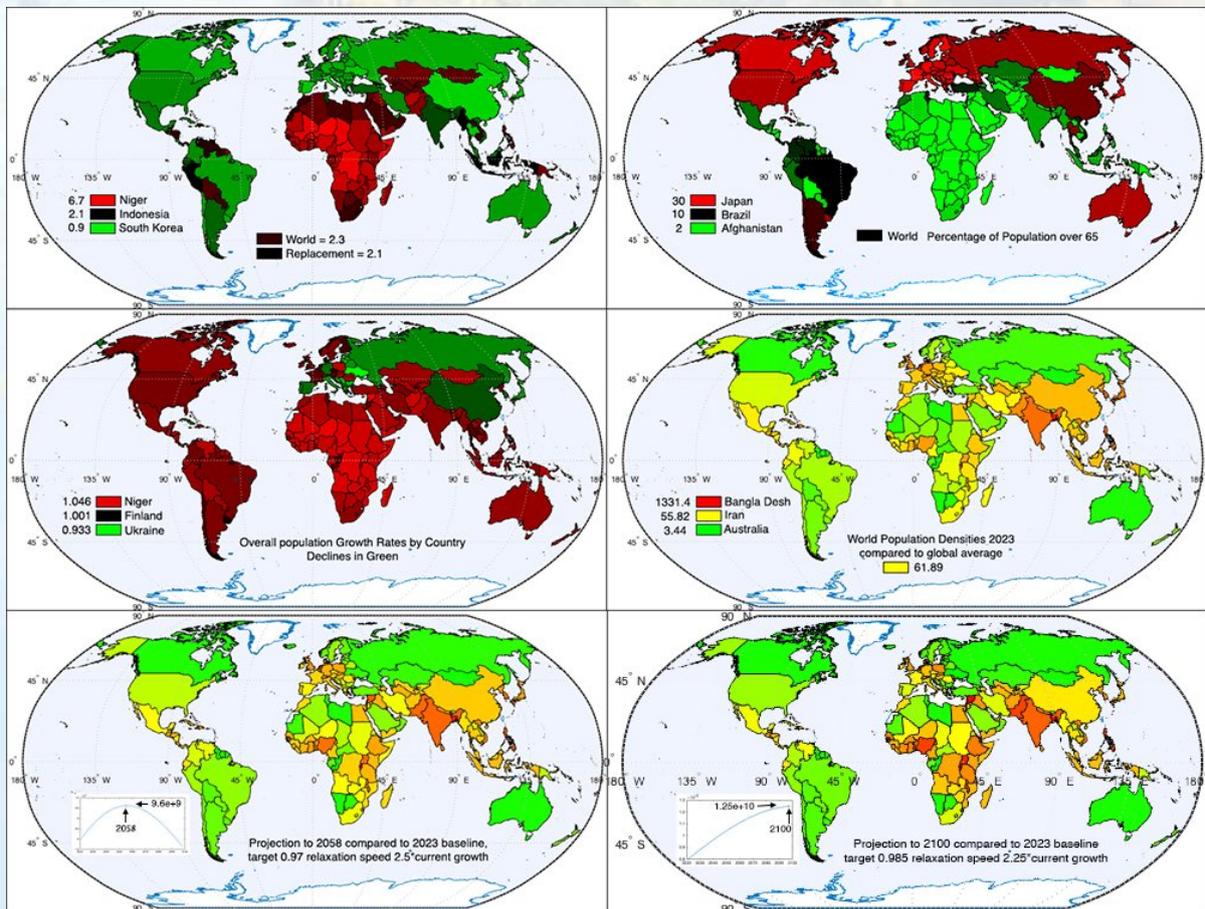

Fig 30: Predicting population (King 2023): (1) UN 2023 fertility rates by country indicate population growth in Sub-Saharan Africa leading to overpopulation with an accelerating trend towards potentially precipitous decline in developed countries. with unsustainably low fertility rates and ageing populations, confirmed by (2) Percentage of people over 65 in 2022 shows populations becoming critically aged due to longer lifespans and lower reproduction rates. (3) Overall population growth rates by country counting all factor, including births, deaths, and migration. (4) Current population densities showing extreme variations in densities between Bangladesh at 1331 and Australia at 3.4. (5) Predicted population densities modelled to be consistent with Watts (2023). In the business-as-usual case, it foresees existing policies being enough to limit global population growth to below 9 billion in 2046 and then decline to 7.3 billion in 2100. (6) Predicted population densities in 2083 consistent with the previous more severe population predictions of Gerland et al. (2014) illustrated in fig 19(1). Both models show a rise in population density in sub-Saharan Africa to peaks of 9.6 bn circa 2058 in (5) and 12.5 bn in 2100 in (6), moderated by population declines in Asia, Europe, the US and Brazil. Heat maps are non-linear, reducing the apparent effects due to the extremes of density between countries. For example the densities for Nigeria in (4), (5) and (6) are 225, 420 and 717 million respectively, reflecting the more severe 2014 prediction.

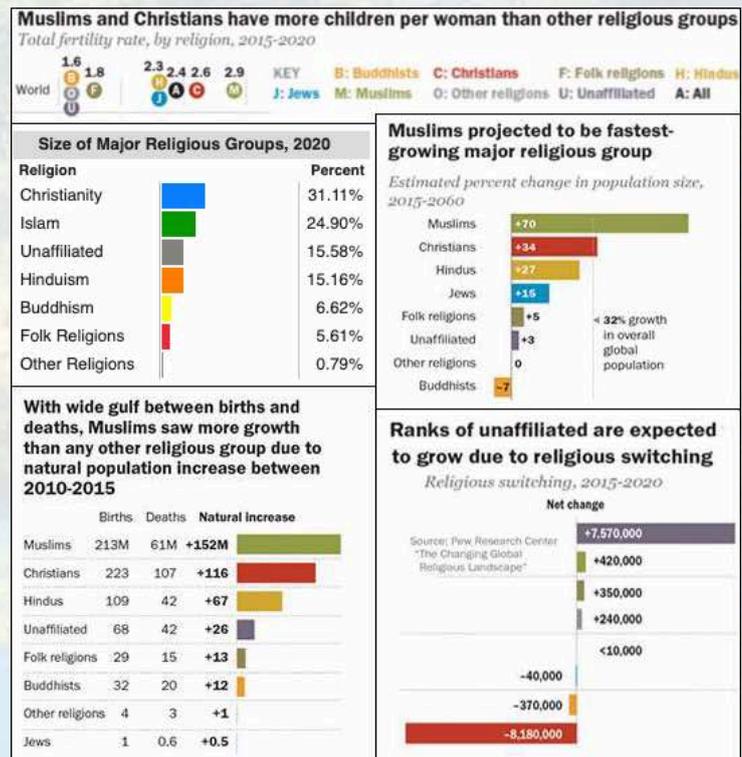

(c) **Population and Patriarchy** Population also remains a critical issue. As of 2023, (fig the issues arising from rapid population decline in developed countries and increasing risks of global conflicts over extreme inequalities and disruptive migration are becoming as serious as the spectre of overpopulation in a boom and bust dilemma. The most recent predictions are for an earlier peak reaching 9 or 10 billion people (Watts 2023) rather than unrestrained growth through to 2100 (Gerland et al. 2014), however the implications for wilderness areas, both in increasingly heavily populated sub-Saharan Africa and the Congo Basin and in the impacts of agri-development in the Amazon, combined with major climatic shifts in viable habitats and productive areas are serious threats. Since the total mass of domestic animals is nearly twice that of humans, a shift away from avid meat consumption, particularly of methane generating beef, is essential.

Symbiotic existential cosmology presents a perspective in which consciousness is not just a human faculty but is shared widely by the biota, conveying at its heart, a reverence for the continuity and sacredness of conscious life. Patriarchal religions and cultures claim to represent the sanctity of life, but have abused it, both by suppressing female reproductive choice to ensure male paternity certainty and by encouraging unrestrained reproduction of their adherents as a means to social and world dominance, accompanied by dire penalties, from stoning for adultery, through enforced female veiling, chaperoning by male relatives, female genital mutilation, limitations on female education, careers and freedom of the female race to associate, and choose their/our own futures and sexual partners.

As noted in Sexual Paradox: Complementarity, Reproductive Conflict and Human Emergence (Fielder & King 2017) this frustrates the evolutionary process towards higher intelligence we have experienced in our XY-chromosomal evolutionary emergence.

Inevitably, whatever the scenario modelled in fig 30, the data confirms that Muslim countries together have a current birth rate of 3.20 versus a worldwide rate of 2.26, and consequently the Muslim countries' share of the world population will rise from 21% to 27% in 2058, based independently on the growth rate projections, above, consistent with Pew Research (2017).

Fig 30b: Recent and future population growth of world religions (Pew Research 2017, Wikipedia).

Christianity and Islam together comprise a majority of the world population with religious believers constituting 84.5% of people. Heaven and Hell cosmology, discarding the living planet and natural diversity, in favour of a reliance on the after life, is in frank contradiction to, and conflict with, ensuring a sustainable and immortal Paradise on Earth. This is not just a crime against nature, it is a crime against humanity and reality itself.

Therefore the main thrust of Symbiotic Existential Cosmology is to change the religious weltanschauung, to that of the living immortality of life as a whole because transforming the religious paradigm is precisely the point of highest remedial capacity.

Both contraception and abortion have been opposed as violating the patriarchal God's invocation to go forth and multiply, playing a central role in driving the population explosion and hence planetary destabilisation. Muslim and secondly Christian birth rates are the highest on the planet. Abortion is opposed as a heinous sin, but the sanctity of life is not just for a single offspring but the viability of our species in a finite enclosed biosphere. Therefore upholding the sanctity of life depends on respecting the ability of the females of the species, who bear responsibility for the ongoing immortal continuity of human life, to make reproductive choices and choices whether to sustain a pregnancy in terms of their bodies, and their future responsibilities, as mothers of children they need to support. At the same

time, beginnings of a severe downturn in reproduction rates insufficient to maintain the population are in some developed countries turning into a flood that is also going to cause a population bust and seriously ageing populations, so both rampant opposition to abortion and the employment and career pressures on women in developed countries need to be removed, so that human population dynamics can become culturally and biologically sustainable.

The Fermi Paradox and Human Extinction

The Fermi paradox is the discrepancy between the lack of conclusive evidence of advanced extraterrestrial life and the apparently high likelihood of its existence. Enrico Fermi's name is associated with it because of a casual conversation in the summer of 1950 with fellow physicists Edward Teller, Herbert York, and Emil Konopinski. While walking to lunch, the men discussed recent UFO reports and the possibility of faster-than-light travel. The conversation moved on to other topics, until during lunch Fermi blurted out, "But where is everybody?"

Fig 30b: (Left) The night lighting of Earth shows planetary evidence of human civilisation visible from space. (Right) JWST galaxy survey shows many early-forming disc-like galaxies similar to the milky way, indicating that the circumstances for life are as favourable as in our own galaxy, but we have no evidence of life elsewhere in the universe other than life on Earth.

The following are some of the facts and hypotheses that together serve to highlight the apparent contradiction:

1. There are billions of stars in the Milky Way similar to the Sun.
With high probability, some of these stars have Earth-like planets in a circumstellar habitable zone.
2. Many of these stars, and hence their planets, are much older than the Sun. If Earth-like planets are typical, some may have developed intelligent life long ago.
3. Some of these civilisations may have developed interstellar travel, a step humans are investigating now.
4. Even at the slow pace of currently envisioned interstellar travel, the Milky Way galaxy could be completely traversed in a few million years.
5. Since many of the Sun-like stars are billions of years older than the Sun, the Earth should have already been visited by extraterrestrial civilisations, or at least their probes.
6. However, there is no convincing evidence that this has happened.

The Drake equation is an attempt to find a systematic means to evaluate the numerous probabilities involved in the existence of alien life where N is the number of technologically advanced civilisations in the Milky Way galaxy: $N = R_* f_p n_e f_i f_c L$ where R_* is the rate of formation of stars in the galaxy; f_p is the fraction of those stars with planetary systems; n_e is the number of planets, per solar system, with an environment suitable for organic life; f_i is the fraction of those suitable planets whereon organic life actually appears; f_c is the fraction of habitable planets whereon *intelligent* life actually appears; f_e is the fraction of civilisations that reach the technological level whereby detectable signals may be dispatched; and L is the length of time that those civilisations dispatch their signals. However, the fundamental problem is that the last four terms are unknown, rendering statistical estimates impossible.

Theories for the lack of evidence of other life in the universe, fall into three major categories:

- (1) **Extreme rarity:** Technological civilisations are extremely rare because extraterrestrial life or intelligence is rare or non-existent elsewhere, due to the extreme rarity of abiogenesis, eucaryogenesis and conscious intelligent organisms, or due to periodic extinction, by natural events, eliminating advanced civilisations as most vulnerable.
- (2) **Self-destructive culture:** It is the nature of intelligent life to destroy itself, or to destroy others.

(3) **Cosmic anonymity:** Other life forms may prefer to remain undetected, have only colonised small parts of galaxies or be unable to assimilate the resources to display evidence of their existence on galactic scales.

The last point may be pivotal. Organismic life, despite its sentient complexity, is the last, lowest energy cumulative interaction of the symmetry-broken forces of nature and the very idea of a biological organism commanding control of energy sufficient to advertise itself across galaxies may be simply a product of human technological hubris and the failure of the out humility to recognise that biological life is a very small player in the cosmic energy equation, although the most complex and conscious phenomenon in the universe.

Nevertheless, we need to heed the warning that, in the absence of knowing there is life elsewhere in the universe, we need above all to respect the sanctity of life on Earth and protect it from a human-caused mass extinction of biodiversity. As Brian Cox on the BBC ahead of COP26 warned, Earth's demise could rid galaxy of meaning Brian notes on the BBC that 'Unique events that led to civilisation mean its demise could 'eliminate meaning in the galaxy for ever'.

The "Great Filter", Hanson (1996), represents the variety natural phenomena that would make it unlikely for life to evolve from inanimate matter to an advanced civilisation. The most commonly agreed-upon low probability event is abiogenesis: a gradual process of increasing complexity of the first self-replicating molecules by a randomly occurring chemical process. Other proposed great filters are the emergence of eukaryotic cells or of meiosis or some of the steps involved in the evolution of a brain capable of complex logical deductions.

1. A planet capable of harbouring life must form in a star's habitable zone.
2. Replicative life must develop on that planet, able to reproduce, using such molecules as DNA and RNA.
3. Simple (prokaryotic) single-celled life must evolve
4. Simple cells (prokaryotes (archaea and bacteria) must evolve into more complex cells (e.g. eukaryotes).
5. Sexual reproduction, which greatly increases genetic diversity, must take hold.
6. Multicellular organisms must develop.
7. Complex organisms capable of using tools must evolve.
8. Those organisms must create advanced technology needed for space colonisation.
9. The spacefaring species must go on to colonise other worlds and star systems, while avoiding destroying itself.

Ward & Brownlee (2000) in their "Rare Earth" hypothesis state a series of worst case scenarios that may have made life on Earth vanishingly improbable and hence also explain why life elsewhere in the universe might not exist. They invoke a number of astronomical worst case claims that make Earth's history exceptional and pivotally cite both abiogenesis – the prebiotic origin of life; and eucayrogenesis – the origin of complex nucleated eucaryote cells as roadblocks, suggesting that nearly all planets might proceed no further than bacterial life.

The processes invoking abiogenesis are a frontier area of scientific discovery that remains to be fully resolved. Organics form a major component of galactic gas clouds such as the Orion Nebula, in which planetary star formation is occurring. Carbonaceous chondrites show presence of biological precursors such as amino acids and nucleotide bases and key steps in the biogenic pathway to replication have been elucidated.

However the endosymbiosis that gave rise to eucaryotes from species of archaea incorporating respiring bacteria in their cell interiors is a natural symbiotic interaction between the two primal cellular life forms that evolved on the planet. Kasting (2001) has refuted these claims of eucaryote improbability:

One point upon which virtually all molecular biologists agree is that the eukaryotic lineage is very ancient. ... The first unambiguously eukaryotic cells (identified by their large size and distinctive morphology) in the fossil record date back to only about 2.1 Gya, whereas molecular evidence for eukaryotes goes back to at least 2.7 Gya (Brocks et al. 1999). The paper also demonstrates that the 2.5-Gya Snowball Earth event (which probably occurred closer to 2.3 Gya) could not have triggered the origin of eukaryotes, as suggested. Eukaryotes appear to have evolved long before this putative catastrophe. So there is no reason to suppose that their appearance required an unusual climatic event.

Furthermore Brocks et al. (2022) note that:

Eukaryotic life appears to have flourished surprisingly late in the history of our planet. This view is based on the low diversity of diagnostic eukaryotic fossils in marine sediments of mid-Proterozoic age (around 1,600 to 800 million years ago) and an absence of steranes, the molecular fossils of eukaryotic membrane sterols. This scarcity of eukaryotic remains is difficult to reconcile with molecular clocks that suggest that the last eukaryotic common ancestor (LECA) had already emerged between around 1,200 and

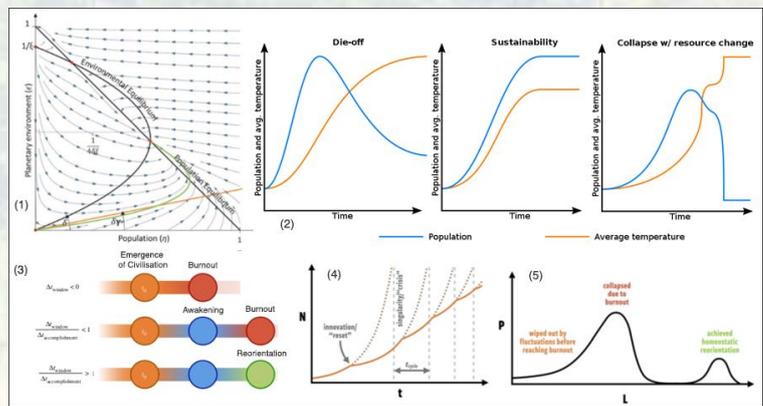

more than 1,800 million years ago. The protosteroids reveal an ecologically prominent 'protosterol biota' that was widespread and abundant in aquatic environments from at least 1,640 to around 800 million years ago and that probably comprised ancient protosterol-producing bacteria and deep-branching stem-group eukaryotes. Modern eukaryotes started to appear in the Tonian period (1,000 to 720 million years ago), fuelled by the proliferation of red algae (rhodophytes) by around 800 million years ago. This 'Tonian transformation' emerges as one of the most profound ecological turning points in the Earth's history.

This brings us to the intervention of **destructive cycles**, both natural and astronomical, and human self-destruct cycles induced by the sheer instability of rapidly evolving technological civilisations and their tendency towards exploitation and internal conflict.

Firstly, we know both the lighter elements of life on Earth along with the heavier elements are produced in cataclysmic events, including supernovae and neutron star collisions, which are themselves potential threats to existing life on nearby planets through intense radiation and black-hole formation. We also know that astronomical collisions are part of the chaotic many-body gravitational dynamics of the universe, resulting in huge collisions such as that which resulted in the Earth-Moon system from a putative collision between Earth and another early planet and which inundated the Earth with asteroid and cometary strikes in the early Hadean era.

Secondly, we know e.g. from fig 19(4) that there have been five great mass extinctions of the diversity of existing life in Earth's geological history, confirming both astronomical impacts and massive atmosphere and ocean changing volcanism have all-but wiped life off the face of the planet.

Fig 30c: (1, 2) Dynamical instabilities between population growth, resource demand and global temperature lead to collapse of society unless resource change sufficiently addresses impacts far enough in advance (Frank et al. 2018, Billings 2018).
 (3) Civilisation leads to burnout unless such resource awakening occurs effectively enough to reorient energy demands before blowout. (4) Growing urban populations can suffer multiple singularity crises requiring homeostatic reorientation, resulting in a bi-modal distribution of failed planetary burnouts and some homeostatic cultures surviving crises (Wong & Bartlett 2022).

This brings us to the emergence of human culture and energy and habitat exploitation, resulting in rapid population growth in the wake of agriculture and animal husbandry, and ensuing human niche construction of urban cultures at the expense of both non-renewable energy resources and the planetary habitats sustaining the biosphere of Earth.

Homo sapiens can survive as a living species only in biospheric cooperation with the other species in the biosphere, particularly, but not restricted to, the species we rely on for food and medicine. We need the full robustness of the genetic and biological diversity of the biosphere to ensure the planet is in a resilient enough condition to last over evolutionary time scales. As can be seen from fig 19b the combined biomass of humanity and livestock is already 22.5 times that of all wild mammals an unsustainable ratio in evolutionary terms. From fig 19(1), although population growth rates have begun to ease, the world population will still rise to 2100 putting severe pressure on sub-Saharan Africa and unsustainable pressure on biodiversity worldwide.

Just as the current investment cycle depends on the futures triple witching hour, not our long-term welfare, not only is our predictable investment horizon less than six months, but we currently lack full confidence of human survival of even a month at a stretch, due to risks of nuclear confrontation and accidental

Fig 30d: Stanislav Petrov and the 1995 Norway rocket launch incident

(a) **Nuclear Holocaust:** We have a significant continuing

chance at any time of all-out nuclear war due to the sheer instability of massive first strike options and the hair trigger decision-making processes that would be set in motion in the event of a nuclear alert. As I write, the war continues in Ukraine, in which specific threats of the use of nuclear weapons have been made. We also know that, even in peace time, we have come very close to accidental hair-trigger mistaken launches. The logic of mutually-assured destruction does not protect us from nuclear war, but converts the situation into a form of global Russian roulette where any mistake could lead to complete Fermi annihilation:

On 26 September 1983, three weeks after the Soviet military had shot down Korean Air Lines Flight 007, Petrov was the duty officer at the command centre for the Oko nuclear early-warning system when the system reported that a missile had been launched from the United States, followed by up to five more. Petrov judged the reports to be a false alarm. His subsequent decision to disobey orders, against Soviet military protocol, is credited with having prevented an erroneous retaliatory nuclear attack on the United States and its NATO allies that could have resulted in a large-scale nuclear war which could have wiped out half of the population of the countries involved.

On January 25 1995, the Norwegian rocket incident occurred, when a team of scientists launched a four-stage sounding rocket to study the aurora borealis. The rocket eventually reached an altitude of 1,453 kilometres (903 mi), resembling a US Navy submarine-launched Trident missile. Fearing a high-altitude nuclear attack that could blind Russian radar, Russian nuclear forces went on high alert, and the "nuclear briefcase" was taken to Russian President Boris Yeltsin, who then had to decide whether to launch a retaliatory nuclear strike against the United States. Russian observers determined that there was no nuclear attack and no retaliation was ordered.

Fig 30: Greta Thunberg submerged by rising oceans. The older generation stealing the future of their offspring and all future generations.

(b) Climate Crisis: We are continuing to fail to meet the targets required to avoid Earth’s climate moving out of the temperature zone of the last million years and into an acutely accelerated warming that could take us back to the Eocene 50 million years ago (fig 19(2)), with a commensurate massive rise in ocean levels and unstoppable ecocrisis, in which major species can no longer survive in their existing habitats. Rather than making a rapid transition to renewable energy, we are supplementing oil and coal exploitation in a short-term economic vicious cycle, and instead we imagine utopian solutions, from massive scale carbon recapture, to geoengineering antarctic glaciers to impede the rising oceans and even mining the moon. These are all desperate technological Fermi extinction scenarios.

Fig 30f: Borneo deforestation

(c) Wild Habitat exploitation: Wherever humanity reaches, particularly by road, the biodiverse wilderness is ruthlessly exploited for beef farms, for agricultural land and for palm oil plantations, and later for urban development This leads to the

most pervasive form of biosphere destruction short of an astronomical impact, by systematic human conversion of the entire land surface area to human production and habitation. Again a Fermi extinction scenario.

Fig 30g: Giraffes die en mass during climate driven drought in Africa. An orangutan confronts a bulldozer deforesting land in Borneo for palm oil plantations. Over 100,000 have died as a result of this activity.

(d) **Biodiversity crisis and Mass Extinction:** Underlying the combined effects of climate crisis and habitat appropriation is the fact that the the Anthropocene, defining Earth's most recent geologic time period as being human-influenced, or anthropogenic, based on overwhelming global evidence that atmospheric, geologic, hydrologic, biospheric and other earth system processes are now altered by humans. This is occurring in a climate of opinion where there is little understanding that human survival depends on a robust evolving biosphere. Our economic targets are so short that we can't even comprehend of a sustainable future 5 years out, let alone a thousand years hence, or the tens of millions of years of stable climate and evolving diversity we need to envisage if we are talking about the survival of humanity as a living species. Biodiversity itself, while concerned words are expressed about the wonders of nature, is far out on the back burner of economic urgency, despite the increasing vulnerability of monoclonal food species to epidemic disease and genetic attrition. This is clearly on its own our most serious cause of long-term Fermi extinction.

(e) **AI takeover:** At the same time, our fixation with physical technologies and materialistic notions of cognition and intelligence, makes it harder and harder for human beings to distinguish themselves from biological machines, which can be superseded by generalised artificial intelligence, and robotic processes, leading to realistic concerns of humanity becoming dependent on AI and losing the autonomous agency to control our own fate as a species.

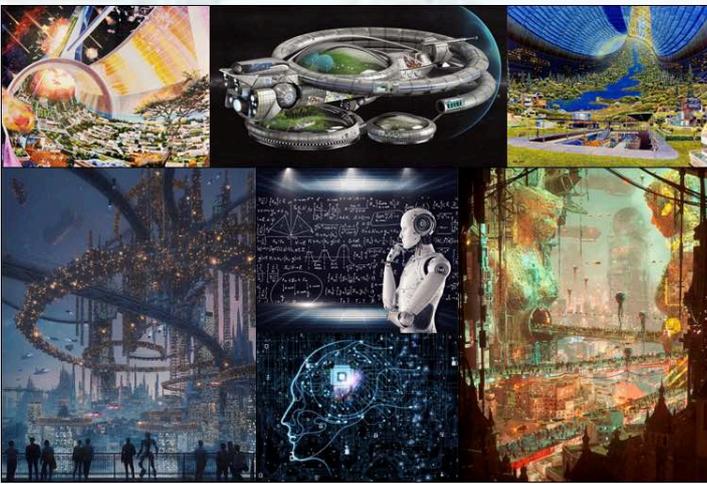

Fig 30h: Technological utopias involve concepts like interstellar travel in “generation ships” where species and genetic diversity is minimal, leaving the “late” planet Earth to an uncertain fate. Dystopias revolve around purely urban “civilisations” in which artificial intelligence dominates and there is no biosphere to support organismic life. None of these scenarios have stability over evolutionary time scales.

(f) **Sheer Cultural and Technological Instability**
Rather than existing in a living world of conscious agents, including other humans, animal predators and in our animistic origins in the gatherer hunter epoch, storms and floods as our existential survival threats, we have surrounded ourselves so completely by machines, and computational devices, that we have reduced the natural world

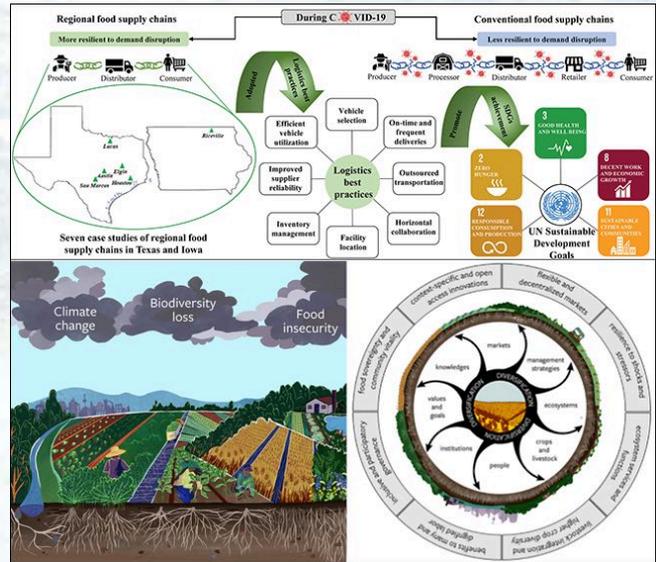

around us to a potentially dystopian mechanism, in which critical infrastructure, from energy supplies to the very food production and supply and transport lanes we depend on in urban societies to survive, are automated beyond our control. Even without a malicious AI takeover, we become a brittle, unstable techno-culture with so many avenues of short term instability, that survival prospects become no more viable than a casual breakdown on the technological highway, from which there is no escape and no return.

Humanity tends to envision future utopias which are purely technological and lack any form of stability over evolutionary time scales, when above all, we need to stop biosphere exploitation and engage sustainable enhancement of the diverse living species our food and medicinal supply and our climatic and biospheric survival depends on. We tend to treat other organisms as “dumb animals” driven by instincts, and see human intellectual achievements as superior and transformative towards a purely technological future, but this absolutely lacks any concept of the stability of life over evolutionary time scales. We see ourselves as moving beyond the evolutionary process, in forms of cultural, intellectual and technological innovation, but these remain tragically unstable on any cosmological time scale. The reality is that evolutionary diversification is the underlying creative process, from which new life forms emerge, and there is no guarantee that humanity will remain the dominant intellectual species, because of it's ill-fated evolutionary dominance. Thus species, from founding primates, to rodents, actually carry more future evolutionary potential than patriarchally dominant Homo sapiens, which is unstably prone to a self-destructive boom and bust “death wish”.

On the wider front, we remain politically and strategically stymied by tribal politics amid the endless exponential growth of GDP economics, which is transparently unsustainable, and a complete inability as a world culture to address the key existential threats to our own survival on Earth as a species as our top existential priorities. We all know this and across the planet, people feel a sense of uncertainty about the future and whether the world is going to be a

viable place in future for their children to survive, yet because of the global power structures and the way political decisions are made, we all feel too helpless to do anything decisive about it and bury our heads in the fog of delusion.

Fig 30i: (above) Food supply chain adaption during the covid 19 pandemic (Marusak et al. 2021) (below) Comparing Adaptive Capacity in Simplifying and Diversifying Farming Systems (Petersen-Rockney et al. (2021).

Humanity has evolved through Machiavellian intelligence to dominate and capitalistically, or militarily exploit one another. For males and male reproductive strategies to collectively dominate the entire female sex and control other living organisms as a dominant patriarchal species, turning to technology as a replacement for living systems is biospheric misadventure. To allow the males of a species, whose investment is principally in fertilisation, rather than the long-term female investment in sustainable child rearing, is committing evolutionary suicide because males risk death to compete for reproductive opportunities and their sole reproductive influence leads to boom and bust instability. We are politically and socially maladjusted to making constructive decisions for the welfare of humanity as a whole, let alone the other species with whom we co-exist and inter-depend. We are completely unaccustomed to living within our means and survive economically on the delusion that endless exponential growth is the solution to the world’s problems. Our global decision-making is driven by authoritarian leadership of a tribal nature, in which populism is rife and Western society is a WEIRD (Western, Educated, Industrialised, Rich and Democratic) minority aberration (Henrich 2020), to the global rule.

Closing the Circle: Doughnut Economies

A revolutionary female-inspired economic antidote to the paradigm of the GDP and exponentiating growth imperatives, comes from Kate Raworth (2012), in her discussion paper “A safe and just space for humanity”, forming an interactive template for regenerating a fair, sustainable social dynamics in the closing circle of the natural planetary ecosystem and environment, originally prepared under the auspices of Oxfam in the run-up to Rio+20. This is built on “A safe operating space for humanity” in which Johan Rockström et al. (2009) propose numerical boundaries for seven parameters: climate change, ozone depletion, ocean acidification, biodiversity, freshwater use, the global nitrogen and phosphorus cycles, and change in land use. The authors argue that we must stay within all of these boundaries in order to avoid catastrophic environmental change.

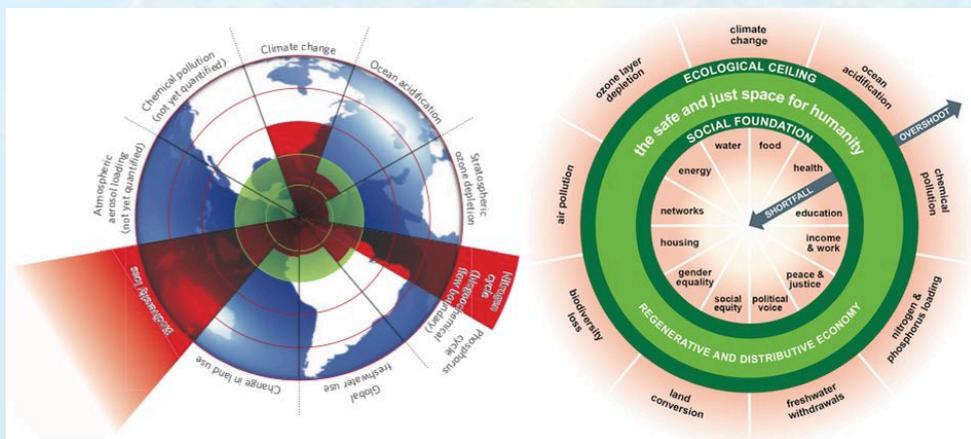

Fig 31: (Left) Beyond the boundary: The inner green shading represents the proposed safe operating space for nine planetary systems. The red wedges represent an estimate of the current position for each variable. The boundaries in three systems (rate of biodiversity loss, climate change and human interference with the nitrogen cycle), have already been exceeded. (Right) The Doughnut Economics model forming a closing circle

balancing the outer limits of the sustainable biosphere with the inner shortfalls of human society spanning health, education, energy, food gender equality and social equity.

In Kate Raworth's words ¹⁸: *The goal of the doughnut is to meet the needs of all people within the means of the planet. Sometimes when I present the idea of Doughnut Economics, people say. "Is this capitalism? Or is this communism? Or is it socialism?" And you think 'Really Are these the only choices we have?' The -isms of the last century? Can we not come up with some ideas of our own and create new names for them and see new patterns?*

Governments in every country are almost addicted to citing GDP figures as if this was proof of success and yet it's so clearly not. Because we have climate breakdown and Covid lockdown and financial meltdown, we have to pursue something far richer to move from this pursuit of endless growth, which we can now see is hitting us with crisis after crisis, moving too a goal of thriving. And the doughnut is possible to turn not into a single number, but into a dashboard. We can hold policy makers to account and say every year you need to talk about how you are making progress on these different dimensions of the Doughnut.

The outside of the doughnut is created by leading Earth system scientists just a decade ago. These are the nine life-supporting systems of planet Earth. To have a stable climate, healthy oceans, recharging fresh water. And they drew these and called them the planetary boundaries. But I thought if we go to the centre of the circle where we use hardly any of the Earth's resources, that's not thriving, that is actually death and destitution for billions of people. We need to convert Earth's lands for food, for water, for housing for energy. So I drew this inner circle and so just as there is an outer limit of humanity's pressure on the planet so too there must be an inner limit. In the hole in the middle is a place where people are left falling short on the essentials of life. It's where people don't have the food, water, energy, healthcare, housing, education, political voice that every person has a claim to meeting. We want to leave nobody in this hole. Get everybody into the green ring of the Doughnut itself.

And I think smart policy makers realised that they don't need a solution to financial crisis and a different one to climate crisis and a different one to health emergencies. They need a paradigm that no longer pushes for endless growth, but instead focuses on thriving, on resilience and on well-being within communities. We began with downscaling in rich cities, in high-income nations because they are the ones that have the greatest obligation to transform, to come back within the planetary boundaries. But I believe the framework that we've created can absolutely be adapted and used in low income countries and cities.

Since 2012, there have been initiatives to downscale the Doughnut Economy, so it can apply to individual countries and cities, starting with developed economies where there is an impending need to face these realities, with projects in Amsterdam and "Regenerate Costa Rica" and the spinoff DASH project where researchers have applied the Doughnut to the needs of 150 countries.

In short: (1) Give half the Earth back to re-wilding the wilderness, so there is enough species diversity for the biosphere to evolve. (2) Transition immediately to renewable energy. (3) Decentralise the food supply chains to protect humanity. (4) Ensure the genetic diversity of our food and medicinal species. (5) Eliminate nukes and consider how best to avoid a massive asteroid Earth strike and protection from a nearby supernova. (6) Teach people how to live in symbiotic urban culture. (7) Use technology for the benefit of life as a whole, not for humanity alone, or an artificial intelligence takeover (Werthner 2022). (8) Celebrate the perennial wonder of existence throughout our generations forever Amen.

"A human being is a part of the whole, called by us the 'Universe,' a part limited in time and space. He experiences himself, his thoughts and feelings as something separated from the rest — a kind of optical delusion of his consciousness. This delusion is a kind of prison for us, restricting us to our personal desires and to affection for a few persons nearest to us. Our task must be to free ourselves from this prison by widening our circle of compassion to embrace all living creatures and the whole of nature in its beauty" (Einstein)

Symbiotic Existential Cosmology is written to fully sacralise nature and the diversity of life as the supreme spiritual meaning of existence, in a universe whose climax is conscious life immortal unfolding in ever deepening illumination.

Karen Armstrong (2022) in "Sacred Nature" notes the urgency of this reflecting Kate Raworth's statement above:

Today that link between nature and humanity has become even more poignant, as we consider the damage we have inflicted on our environment. We cannot delight in nature any more without knowing that we face the urgent task of saving it from human destruction.

In the dynamic of concentric circles, of "The Great Learning" (Bloom 1999), the extension of each circle signifies a moment when we are compelled to transcend ourselves and our obsession with "me" and "mine." The Chinese rituals of family life were painstakingly contrived to make this expansion of sympathy habitual. But to that we should add a new circle, which transcends our focus on humanity. When finally we realise that our very existence depends upon nature, it will be time to surrender our anthropocentrism and include the entire cosmos in our ultimate concern. The Confucian scholar Tu Weiming (1998) argues that we must go beyond the

¹⁸ <https://www.bbc.co.uk/reel/video/p08hppxt/how-the-dutch-are-reshaping-their-post-pandemic-utopia>

secular humanism that formed the anthropocentric ethos of the Enlightenment. We should develop an anthropocosmic mentality that unites the individual with the community and preserves the harmony between the human species and the non-human world.

Psychedelics and Planetary Reflowering

The relation of psychedelics to Fermi extinction is the reason Symbiotic Existential Cosmology was written and why psychedelics have a key role in saving humanity from both an apocalyptic extinction, and a slow decline back to an oblivion of dark ages from which culture cannot recover.

The nascent reality connecting psychedelics and the Fermi paradox is that evolution climaxing to the emergence of a dominant cultural species like Homo, involves a narrowing of the experiential filters of conscious experience in the brain to promote species dominance, which then becomes a critical flaw, in a breakdown of coexistence into predatory exploitation, precipitating a mass extinction of the diversity of life through habitat destruction and the depletion of resources, in a non-renewable energy consumption and population burst, causing severe climatic change and disrupting planetary habitats on a global scale. This is the Fermi apocalypse catastrophe we are witnessing.

Fig 31b: Arbol de Ruben Huichol

The natural antidote to the destructive Fermi apocalypse is that the kind of climax, driven by a dominant cultural species also occurs at peak biodiversity, after a long period of fecund prosperity, in our case since the Tertiary-Cretaceous extinction, and this results in a 'salting' of the biosphere with biomolecules, which can modulate the neuronal activity of a dominant species in such a way as to carry its conscious neurodynamics closer to the climax edge of experiential chaos than its own evolutionary species selection became adapted for, thus opening the mind of humanity to the totality of existence that lies at the source of all spiritual experience of transcendence, but in a way that is fully entangled with the diversity of life, as a biospheric sacrament. This is then a way that the fullness of evolutionary climax comes to reestablish the symbiotic biosphere, because changing the consciousness of the dominant species liberates it from its evolutionary constraints. Because any dominant cultural species seeks to understand what the hell it is doing in the universe, this becomes a catalyst for its own self-discovery.

Fig 31c: (Top) DMT-bearing plants are widespread. *Phalaris arudinacia*, *Psychotria viridis* and *Acacia phlebophylla*. (Bottom) Mescaline-bearing cacti *Lophophora williamsii* and *Trichocereus pachanoi* have no close taxonomic relationship nor overlapping locale, suggesting a similar defence to insect predation.

This is not a magic process of divine psychedelic intervention. Of the three classic psychedelics, dimethyl-tryptamine (DMT) and its related compounds such as 5MeO-DMT are widespread across species. DMT is an endogenous compound found in both animals (Saavedra and Axelrod, 1972; Christian et al., 1977) and a wide variety of plants around the globe spanning both monocot grasses and dicot lowering plants. Major plant genera containing DMT include *Phalaris*, *Delosperma*, *Acacia*,

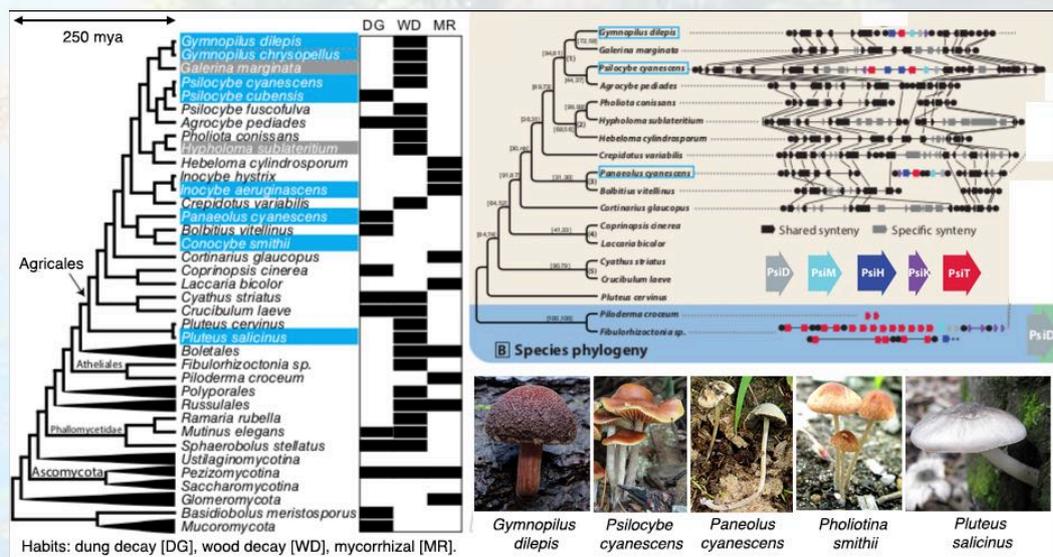

Desmodium, *Diplopterys*, *Mimosa*, *Virola*, and *Psychotria*. It has even been proposed that it plays an endogenous role neurologically in human beings (ibid). *Phalaris* grass species for example are known to contain the alkaloids DMT, 5-MeO-DMT, and 5-OH-DMT (bufotenin), which also occurs in toads, but also gramine (Pasos & Mironidou-Tzouveleki

2016), which is neuro-toxic in herbivores. DMT is traditionally consumed as ayahuasca, a mixture of *P. viridis* and *Banisteriopsis caapi* “the vine of he soul”, which contains the monamine-oxidase inhibitor harmine.

The occurrence of mescaline is less widespread, confined to two unrelated cactus genera, the peyote cactus *Lophophora williamsii* and several *Trichocereus* species, including *T. pachanoi*, the San Pedro cactus. This suggests that mescaline and the wider variety of bitter alkaloids in peyote have arisen through a response to insect predation.

The status of psilocin appears to be similar to mescaline and is even more intriguing. The incidence of psilocin activity is not taxonomic with the evolutionary tree, but is scattered across diverse genera of Agaricales. The active species share both dung and a rotting wood habits and do not have a mycorrhizal symbiotic relationship with plant roots, as related non-active species do, indicating their activity is an adaptive response to competition with insect varieties which also exploit these habitats. Reynolds et al. (2018) have established that a complex of five genes appears to have been horizontally transferred together from the wood-decomposing species to the dung species. The phylogenies of PS genes suggest they originally served roles in the wood-decay niche among fungi, and more recently emerged through both vertical and horizontal transfer in dung-decay fungi possibly in association with the rise of grasslands and megafauna in the Eocene at 50 mya. Horizontal transfer and retention of PS clusters are evidence of selection on the PS pathway in the recipient lineage. This suggests that the genes form a complex that can be transferred together by a transposable element which confers resistance to predation. The lead author Jason Slot notes: “The psilocybin probably doesn't just poison predators or taste bad. These mushrooms are altering the insects' 'mind' – if they have minds – to meet their own needs.” Serotonin shares psychodynamic survival function across all Bilateria, spanning arthropods and vertebrates, so it has been suggested that their role has been to deter insect consumption, possibly via a non-lethal psychoactive appetite suppressant based on the known olfactory role of 5HT2a receptors in fruit flies (Huser et al. (2017), although the spread of *P. cubensis* is also specifically associated with Brahman cattle.

Fig 31d: Analysis of horizontal transfer of psilocin synthesis genes between fungi.

But this explanation reveals the other good half of the Fermi paradox. A dominant species which discovers its psychic species and learns to use their paradoxically disturbing properties, and begins to protect

and even cherish its biosphere as sacred and integral to the evolving cosmic “design”, for the lack of a better word, and thus, instead of proudly announcing its dominant existence to all comers, or failing one of the many triple witching hours of its own cultural, political, economic and environmental instabilities, instead settles into discovering the abyss of its own conscious experience as a convergent symbiosis with the conscious universe as a whole.

This is what I term **cosmological symbiosis**, thereby settling into a much more cerebral perennially immortal existence, complemented by the use of renewable technology and adroit strategies to protect the biosphere from astronomical crises, such as massive impacts and nearby supernovae, by careful use of its solar system habitats to avoid putting all its eggs in one basket and to remain concealed in the universe at large, to avoid predatory exploitation from without. This is **Fermi paradise on the cosmic equator in space-time**.

Critical to addressing our existential threats to survival is the ability of subjective conscious volition to have efficacy over the physical universe. The history of neuroscience and consciousness research has been plagued by the notion of epiphenomenalism, in which the conscious mind is given the “ghost in the machine” status of an internal model of

reality constructed by the physical brain, while subjective conscious volition over the physical universe is disregarded entirely as an impossible option to accept, because of the devotion of physical science to purely mechanistic principles, particularly those expressed in physical behaviour. This is why Symbiotic Existential Cosmology has a core empirical principle that **subjective consciousness has efficacy of volition over the physical universe**, which we can each affirm at once through simple physical affirmation, as is central in the law on both criminal and corporate intent..

The failure to accept this foundation feeds into our entire existential dilemma, because we then accept the abandonment of personal responsibility for our fates in all the existential threats facing our species. We have drifted into accepting the notion of nuclear deterrence, as tacit acceptance of the necessity for ever refined and more automated forms of nuclear weapons, when this just perpetuates humanity's genocidal tendencies, as the Mayor of Hiroshima lamented after the G7 summit. We accept climate crisis as a fact of economic existence, whatever the ultimate costs to the diversity of life, and human welfare and futures. We are ruthlessly exploiting all the wild habitats of the planet, leaving no room for life as a whole to flourish. We are now in the process of reinventing ourselves as biological forms of artificial intelligence, reducing our intentionality and creative insights to mere computational processes, and homeostatic mechanisms. All this is leaning towards Fermi extinction by cultural instability. That is why I am acting to heal the apocalypse of life and doing it now.

Self-mechanisation constitutes a complete abandonment of our essential being, and our sense of personal responsibility for our fates, both because existential issues seem too huge and all-embracing to address, but also because we have abandoned our very notion of being intentional beings able to alter our destiny for the future of life as a whole, in the pursuit of a degenerate mechanistic identity. At the centre of the cyclone is not consciousness, but the ability of subjective consciousness to change the physical world around us, through conscious volition, as clearly expressed in our intentional physical behaviour, so that we and our offspring and all the sentient living creatures we are surrounded by, can continue our struggle for illumination and transcendence together. Pure materialism seeks to deny subjective conscious autonomy as a key way to prove the rule of mechanism, by deconstructing volition as brain based purely physical neural outputs, when consciousness itself is too elusive to attack. This is root misadventure.

Over the last few weeks Christine and I have spent a lot of time watching David Attenborough narrating the last few years of his documentary programs and what was utterly striking was the unrelenting conscious volitional will and sheer determination of seemingly dumb animals, and the plants and fungi, to struggle, not just for their own survival, but the flowering of life in each species, caring with utter resourcefulness for their offspring and for the evolving future of life, through the web of their interactions, as plant and fungal producers, herbivores, and carnivores, amid the tooth and claw of predators and prey, and parasites and hosts, to form the climax network of living diversity.

What is gobsmacking – outstanding in its sheer intensity, is that all these supposedly dumb organisms are intentionally creating and perpetuating life around us under extreme stresses of near starvation, food searches over hundreds of kilometres for their young, new born offspring having to depart without food, to fly or swim in one stretch, half-way across the planet to seasonal feeding grounds with mothers struggling to avoid all their offspring being consumed by predators along the way. All these species have the will to live and to perpetuate life as a sine qua non, except we ourselves, who can't even accept we have any ability to do so because our mechanistically computational physical brains made us do it! Hence it is key to **know** that subjective conscious volition has efficacy over the physical universe.

I summoned this “gnosis”, without fear or favour, when I made my millennial vigil to the Amazon and Jerusalem. I knew the odds and knew I was on the side of life against monotheistic doctrine, of dominion over nature and woman alike, as a catcher in the rye, passing right through the monotheistic throng, carrying the entheogenic sacramental holy grail of the Western religious tradition in my blood. I knew I was facing three major world religions with vested interests and violent tendencies. I didn't try to confront or argue fine points of law, and sought simply to find common ground with liberal rabbis of both sexes, and perform a quick passage, as Jesus did, after preaching in the synagogue at Nazareth and passing cleanly through the crowds seeking to throw him off the cliffs for blasphemy. So I held simple rites of passage – to **unfold the promised epoch of the Tree of Life**, throw open **the Gates of Compassion** and **celebrate the Hieros Gamos of woman and man**, in the **Song of Songs**, fulfilled in my subsequent pilgrimage to pay my respects to Kali in Varanasi, completing my academic sabbatical. These are the three core principles of natural redemption that heal the apocalyptic tradition in a true unveiling of the immortal abundance of life.

Psychedelics in the Brain and Mind

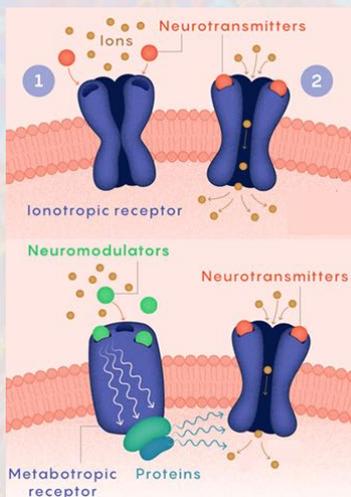

While the brain is an electrochemical organ, whose excitations are pulses and waves of electrical excitation, communication between neurons is predominantly biochemical, via synaptic bulbs which release neurotransmitter molecules that bind to receptor proteins in the membrane of the target neuron that are either ionotropic and open ion channels, causing an electrical voltage, or metabotropic, activating proteins which alter the target neuron response.

There is widespread agreement that all neurotransmitters, like dopamine, can act as neuromodulators under certain conditions. Which role a molecule is playing in given circumstances tends to be defined by its function and activity. In general, neurotransmitters are released from one neuron into the synaptic space that connects it to another neuron; within milliseconds, they cause the gates of ionotropic receptor proteins to open and allow ions and other charged molecules to flood into a neuron, changing its internal voltage. Once the voltage passes a threshold value, the neuron fires an electrical signal to other neurons.

Fig 32: Left: Serotonin 5HT_{2a} receptors are widely distributed across the cortex (Stein 2007). Centre: Ascending serotonin and nor-epinephrine pathways from basal brain centres fan out across layers of the cortex, modulating modes of sleep, wakefulness, mood, vigilance and drive. Right: 5HT_{2a} receptors line pyramidal cells traversing the cortical layers.

In contrast, neuromodulators are often released en masse at sites all over the cortex to seep through brain fluid and reach many more neurons. Binding to metabotropic receptors, whose protein cascades can affect both the nucleus and modulate neighbouring receptors, they act over seconds and minutes to make it more or less likely that the neuron will fire an electrical signal. They can alter the strength of connections between neurons, turn up the “volume” of certain neurons compared to others, and even affect which genes get turned on or off. These changes happen to individual neurons, but when a whole network is blanketed with neuromodulator molecules landing on the receptors of thousands or millions of neurons, due to major ascending pathways such as those of serotonin, nor-epinephrine, dopamine and acetyl-choline the molecules can “wash” into the intercellular fluid creating neurosystem-wide effects which influence every neural function, from sleep-wake cycles to attention and learning.

Eve Marder, recognised for her pioneering studies on neuromodulators notes: *By washing through the brain, neuromodulators allow you to govern the excitability of a large region of the brain more or less in the same way or at the same time. You're basically creating either a local brain wash or more extended brain wash that is changing the state of a lot of networks simultaneously.*

Fig 33: Metabotropic and ionotropic actions of neurotransmission and neuromodulation.

The primary excitatory neurotransmitter is the amino acid glutamate and the primary inhibitory one is gamma-amino-butyric acid or GABA, modulated by alcohol and sedatives. Their mutual interaction generates waves of excitation and inhibition identified with brain activity in the electroencephalogram.

Other neurotransmitter molecules including serotonin (5-hydroxy-tryptamine derived from the amino acid tryptophan), nor-epinephrine and dopamine (derived from tyrosine) have a modal modulating effect on brain activity mostly through slower-acting metabotropic receptors. Serotonin and nor-epinephrine pathways regulate modes of organismic behaviour, including sleep and mood in serotonin, vigilance in nor-epinephrine, and reward seeking in dopamine. The level of neurotransmitters in the synaptic junction is also regulated by transporter proteins which mop up unused neurotransmitters after the event, to avoid the brain being flooded with effects that are now over.

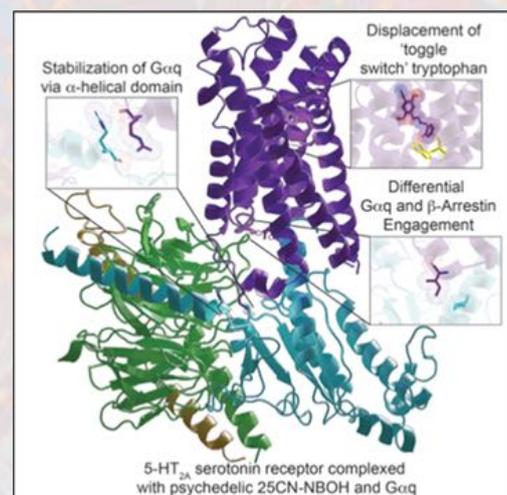

Each of the classical neurotransmitters have both ionotropic and metabotropic receptors as targets with the exception of mono-amines, where only the serotonin 5HT₃ receptor is ionotropic and differs structurally and functionally from all other metabotropic receptors which are hepta-helical G-protein-linked and all have a common evolutionary tree universal to life, fig 115. Postsynaptic 5-HT₃ receptors mediate fast excitatory synaptic transmission in neocortical interneurons, amygdala, and hippocampus. Nicotinic acetylcholine receptors are ionotropic. At the neuromuscular junction they are the primary receptor in muscle controlling muscular contraction. Muscarinic acetylcholine receptors are metabotropic and modulate alertness. Glutamate has both ionotropic NMDA and AMPA receptors and metabotropic mGlu receptors. GABA A receptors are ionotropic while B are metabotropic. The 5-HT₃, nicotinic and GABA A receptors all consist of five subunits arranged around a central ion conducting pore.

The term “psychedelic” has been eloquently (and compellingly) defined by Grinspoon and Bakalar (1979) to indicate “A drug which, without causing physical addiction, craving, major physiological disturbances, delirium, disorientation, or amnesia, more or less reliably produces thought, mood, and perceptual changes otherwise rarely experienced except in dreams, contemplative and religious exaltation, flashes of vivid involuntary memory, and acute psychosis.” The classic psychedelics, including psilocin, mescaline, dimethyl-tryptamine and LSD all have a common action on serotonin receptors in the brain. By interrupting psychedelic action with an inhibitor, Franz Vollenweider et al. (1998) established that the principal action of psychedelics was at the serotonin 2HT_{2a} receptor, widely distributed in the cortex, fig 34(a), and densely expressed in layer 5 pyramidal neurons. Their detailed interaction with the spectrum of brain receptors can be seen in fig 34(h) and the close relationship between psilocin (4-hydroxy-dimethyl-tryptamine) and serotonin (5-hydroxy tryptamine) in fig 34(i).

Serotonin has multiple modal behavioural roles in the brain as a regulator of sleep and mood. The class of anti-depressants called SSRIs, or selective serotonin reuptake inhibitors, increase the levels of serotonin by inhibiting its reuptake by transporter proteins. Entactogens such as MDMA, or ecstasy, go further and reverse the transporter, so as to dump an acute dose of serotonin, leading to the entactogenic high, accompanied by pleasurable and affectionate interpersonal contact. Both these agents can subsequently lead to serotonin depletion, the “Tuesday blues” or longer term withdrawal effects in antidepressants, but neither induce the psychedelic state. By contrast psychedelics have little physical dependence potential, because the acute effects rapidly wane if they are repeatedly dosed, until after a refractory period of days.

Outlines of an understanding of how psychedelics act have required protracted investigation and are still under exploration. Psychedelics are agonists that turn on serotonin receptors, rather than blocking their action, just as is serotonin itself, but the way psychedelics do this seems to involve a distinct protein cascade. As shown in fig 34(b), while all serotonin agonists activate the protein *c-fos*, psychedelics also activate the developmental protein early growth response 2 or *egr-2*. Fig 34(c) shows this is confirmed in vivo in mice. There has also been found from multiple researchers to be interactions between 5HT_{2a} and metabotropic glutamate MgluR2 receptors, fig 34(d) involving psychedelics, which may explain how psychedelics, in addition to causing a standard serotonergic effect, also have the bizarre sensory and existential effects they are renowned for, by modulating excitatory glutamate activity. Kim et al. (2020) have further explored the relation between psychedelics and the G α q subunit of the heterotrimeric G-protein responsible for psychedelic activation and its deactivation by β -arrestin.

Fig 33b: Full psychedelic agonist psychedelic 25CN-NBOH — 5HT_{2a} coupling involving differential G α q and β -arrestin engagement (Kim et al. 2020).

When we come to studying the effects on the brain in electrical and metabolic brain studies, the results are complex. There are two principal ways of studying brain activity, one is to place electrodes, or superconducting magnets on the scalp and record the electrical activity in electro- and magneto-encephalograms (EEG and MEG) and the other is to use metabolic measures using functional magnetic resonance imaging (fMRI), or positron emission tomography (PET) requiring a radio-active tracer. fMRI BOLD uses blood oxygen level dependent imaging and PET can sample for glucose.

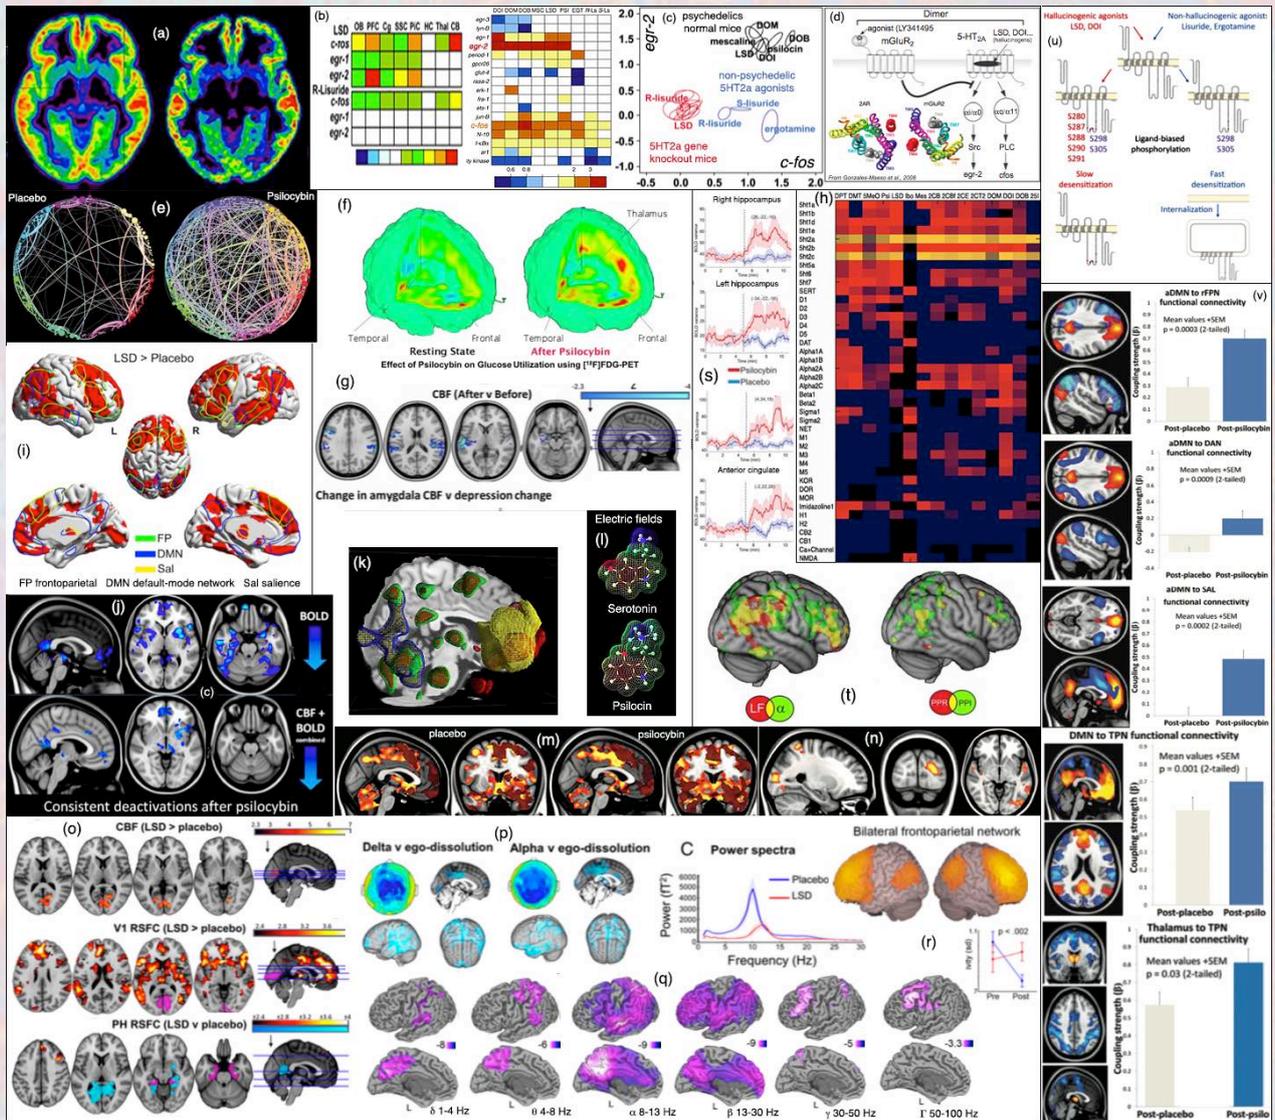

Fig 34: (a) Left healthy person's excitatory 5HT2a receptors are widespread across the cortex. Mentally "at-risk" patient right shows lower activation (Hurlemann et al 2008). (b) In vitro and (c) in vivo investigation of protein activations caused by 5HT2a has shown a consistent differential activation of *egr-2* (early growth response 2) transcription factor in psychedelics, as opposed to universal activation of *c-fos* (Nichols & Sanders-Bush 2002, González-Maeso & Sealfon 2003, González-Maeso et al 2007). (d) Serotonin agonism also appears to be linked to a pairing of 5HT2a with an adjacent glutamate mGluR2 metabotropic (G-protein-linked) receptor where *egr-2* is blocked by an mGluR2 agonist (Bockaert et al, Fribourg et al, Kondo & Sawa, Uslaner et al, Gewirtz & Marek, Delille et al). (e) Persistence homological scaffolds for placebo (left) and psilocybin (right) showing greater inter-connective persistence (Petri et al). (f) PET study of 15-20 mg psilocybin taken orally over a 48 minute period 90 minutes after consumption, which shows frontal activation by comparison with a resting state (Vollenweider et al 1997). (g) Reduction in amygdala activity in patients with treatment-resistant depression. Stabilisation of the DMN also occurred. Half of patients ceased to be depressed and experienced changes in their brain activity that lasted about five weeks (Carhart-Harris R et al. 2017). (h) Heat map of normalised receptor interactions (Ray 2010). Activity dark blue=0 to red=4 (orange for 2a and 2c, black no data). (i) LSD increases global functional connectivity of higher-level integrative cortical and sub-cortical regions (Tagliazucchi et al. 2016). (j) A recording during the 12 minutes after intravenous administration of psilocybin 2mg (~15 mg orally), which shows reduced activity in medial frontal cortex (mPFC), posterior cingulate cortex (PCC) and other areas (Carhart-Harris et al 2012a, Lee & Roth). (k) PET study of 5HT2a sites where psilocybin acts, with red and yellow having highest density (Hasler & Quednow). (l) Comparative electric fields of serotonin and psilocin. (m) Increases in activity associated with autobiographical memories on psilocybin. (n) Greater late phase activations during autobiographical recollection under psilocybin than placebo (Carhart-Harris et al. 2012b). (o) Changes in fMRI whole cerebral blood flow (CBF) on LSD, resting state functional connectivity (RSFC) increased between V1 and a large number of cortical and subcortical brain regions, but decreased between the parahippocampal (PH) and the retrosplenial cortex (RSC) and PCC, although increased between the PH and dorsal mPFC and right dorsolateral prefrontal cortex (Carhart-Harris et al 2016a). (p) Reductions in alpha (8-15 Hz) and delta (1-4 Hz) MEG power with ego-dissolution on LSD attributed to cortical desynchronisation (Ibid). (q) Corresponding decreases in MEG for psilocybin (Muthukumaraswamy et al. 2013). (r) Source localisation of one of several networks with reduced power, again associated with desynchronisation (Ibid). (s) fMRI BOLD Variance time courses into the four regions of peak statistical significance for psilocybin and placebo. (t) Statistical significance for decreased low frequency power (LFP) and power spectrum scaling exponent α after psilocybin infusion. Statistical significance of increased power point rate (PPR) and decreased point process interval (PPI) after psilocybin infusion (Tagliazucchi et al. 2014). (u) Distinct receptor phosphorylation barcodes in psychedelics. (Vandermoere & Marin 2014). (v) Increased functional connectivity after psilocybin between the DMN and (i) r-fronto-parietal, (ii) DAN dorsal attention network, (iii) SAL salience network, (iv) TPN task positive network, (v) thalamus to TPN (Carhart-Harris et al. 2013), consistent with the "unconstrained mind" (Lifshitz et al. 2018).

While one might expect that something causing visions, or even hallucinations, might result in enhanced brain excitation, some aspects of the psychedelic state, such as ego loss might also arise from a reduction in activity. Early scans of subjects on psilocybin, fig 34(f) indeed showed increases, as has a later study on LSD when the visual areas are examined, fig 34(o), but the scientific community was surprised when a team led by Robin Carhart-Harris and David Nutt, fig 34(j), found that there was a significant and unexpected reduction in activity. At the time, Franz Vollenweider commented: *“We have completed a number of similar studies and we always saw an activation of these same areas. We gave the drug orally and waited an hour, but they administered it intravenously just before the scans, so one explanation is that the effects were not that strong.”* Carhart-Harris et al. injected psilocybin and waited only a short period before the scans began. Psilocybin is a pro-drug, which is converted to psilocin, the active ingredient. The former is converted to the latter both by stomach acids and in the liver by alkaline phosphatase (Dinis-Oliveira 2017).

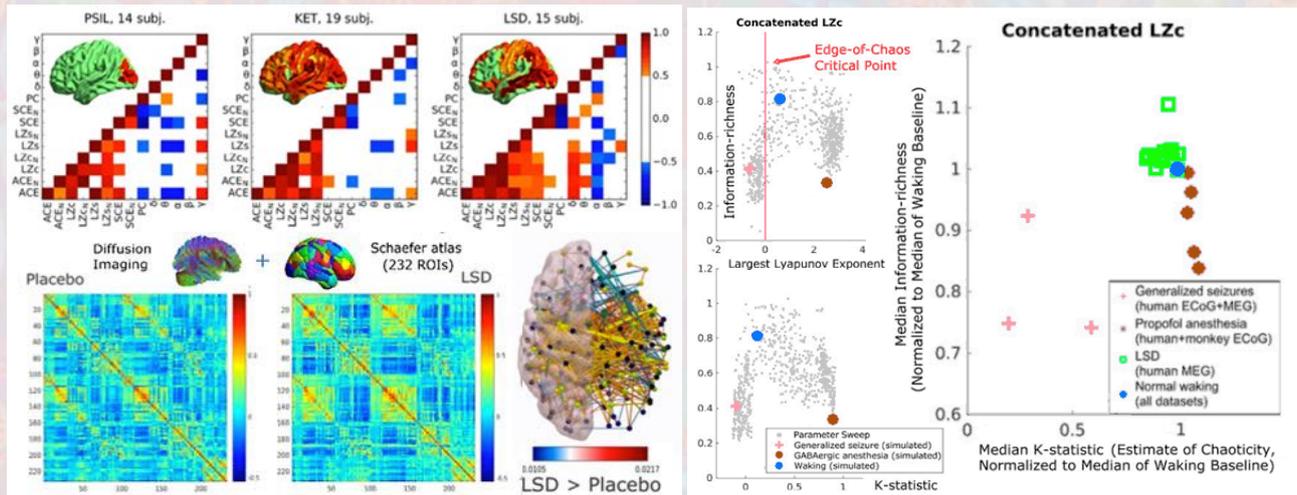

Fig 35: LEFT (Above) MEG complexity measures are greater for waking consciousness than sedative-induced anaesthesia, but greater still for psychedelics. Increased complexity and correlations of measures. For all three there is reliably higher spontaneous signal diversity, than placebo even when controlling for spectral changes (Schartner et al. 2017). Below left: Structural-functional similarity calculated as the Spearman correlation between vectorised structural and functional connectivity matrices. Below right: Brain networks of significant functional connectivity differences (r values) between placebo and LSD. LSD makes globally segregated brain sub-states more complex and more decoupled from structural constraints, as well as reducing functional connectivity of the anterior medial PFC, which is thought to subservise processes of reality monitoring (Luppi et al. 2021). RIGHT: Upper Left: Simulation of Lempel-Ziv complexity against Lyapunov exponent measured for a deterministic system. Lower left: The same measure in terms of the experimental K-statistic. Right: LSD, propofol anaesthesia and seizures normalised to the conscious state show that LSD enhances complexity, and brings the conscious brain state closer to edge-of-chaos criticality (Toker et al. 2022).

However Robin Carhart-Harris subsequently associated these results with a reduction in the activity of the default mode network (DMN). This was discovered a few years earlier from a pattern of apparent reductions in activity in certain areas during specific tasks that showed up as increased activity when resting (Raichle et al. 2001, Raichle & Snyder 2007). The DMN is thought to have a critical survival role in formulating responses to actual or incipient crises, making active use of the brain during down times from activity to be better prepared. In fact there are many resting state networks and the fundamental idea is that the brain has two complementary modes of activity which can occur together, a passive role responding to incoming environmental or sensory priorities and an active role generating activity beneficial to the organism's survival, with both of these processes superimposing during activities, so one or the other appears more prominent. Areas noted in these studies as having reductions were the medial frontal cortex (mPFC), posterior cingulate cortex (PCC), parahippocampal (PH) and the retrosplenial cortex (RSC). The PCC in particular is characterised in measuring how much you are “caught up” in your feelings and responses, as opposed to just having them. Carhart-Harris et al. (2013) also investigated (v) the connection between the DMN and other networks such as the saliency (SAL) and dorsal attention (DAN) networks and found psilocybin increased functional connectivity between several areas which normally have orthogonal non-interactive relationships confirming the increased functional connectivity of diverse regions under psychedelics.

Carhart-Harris cites the results as evidence of a reduction in default mode network activity consistent with silencing the internal dialogue and ego loss (Pollen 2018). A second researcher Justin Brewer has also found a similar reduction in people meditating (Brewer et al. 2011). This has led to the idea that stopping the internal dialogue of the default mode can result in ego dissolution, because the distinctions between self and other become blurred and the role of the ego as the strategic basis of the default mode network means that silencing it could induce a state of union, in

which self and universe become one. Functional imaging has linked the precuneus, an integral component of the default mode network to the processes involved in self-consciousness, such as reflective self-awareness, that involve rating one's own personality traits compared to those judged of other people (Cavanna & Trimble 2006). This thesis supports the notion that both psychedelics and meditation can induce states of ego loss, but the effects of psychedelics are very profound and striking and experientially different from a meditative state of controlled repose, so quietening the resting state networks is a necessary gateway to both, but is not sufficient to explain the vast experiential territory of the psychedelic conscious state.

Carhart-Harris, Fortier, & Millière (2017) note the collapse of duality: *The DMN is usually associated with mind-wandering, self-reflection and introspection while the Task Positive Network (TPN) is associated with the orientation of the mind towards the external world. Elaborating on this distinction, you notice that these two networks are anti-correlated in order to guarantee the functionally important distinction between the internal world and the external one. Now, with your colleagues, you have shown that the DMN/TPN anti-correlation is significantly decreased after psilocybin intake. You have proposed that the diminution of the orthogonality between the DMN and the TPN was a very plausible explanation as to why psychedelic experiences are characterized by a "collapse of dualities" and by the "disturbance in one's sense of self, and particularly one's sense of existing apart from one's environment"* (Carhart-Harris et al., 2014, 16).

Millière R et al. (2018) express psychedelic ego dissolution this way: *"even forms of putative "total" self-loss involving the radical disruption of both narrative and multisensory aspects of self-consciousness are best thought of as a family of states which can differ from a phenomenological perspective with respect to variables that are not directly related to self-consciousness. Indeed, strong forms of drug-induced ego dissolution may involve a very vivid and rich sensory phenomenology, perhaps as a result of decreased sensory gating, while available evidence on some "selfless" states induced by meditation suggests that their phenomenal content is very sparse (e.g., in states of so-called "pure consciousness" achieved in Samadhi practice)."*

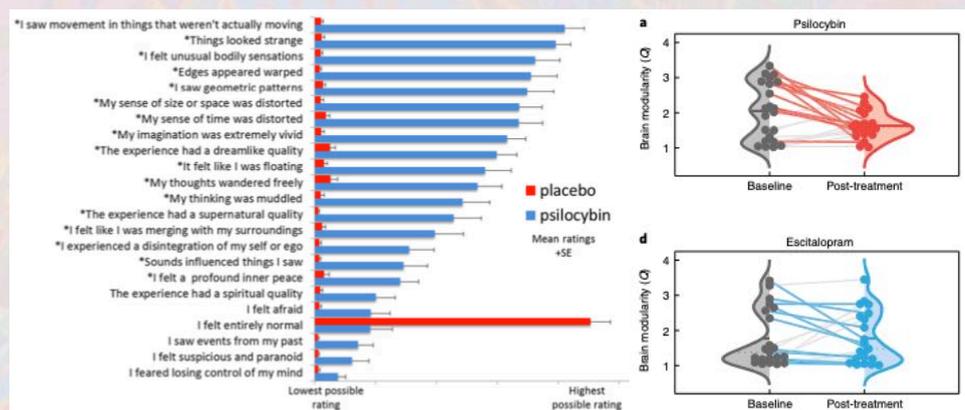

Carhart-Harris also compared the degree of reduction with subjects' personal reports of the experience during the session and found that the reduction was greater in subjects who reported evidence of ego or subject-world dissolution such as *"I existed only as an idea, or concept"*, or *"I didn't know where I ended and my surroundings began"*, suggesting the effect is genuine. The result is also consistent with heightened activity in other brain areas, particularly those involved in the subjective effects of visions and synesthesia ¹⁹, which would tend to affect sensory areas rather than associative or frontal areas.

Subsequent studies, both on psilocybin and LSD using MEG fig 34(p, q), give further insights into this situation. The psilocybin study was again by injection but the listed subjective responses showed marked effect differences between subject and placebo, indicative of the psychedelic state. In both studies there was found to be a reduction in oscillatory power, which in the LSD study was strongly associated with ego loss.

Fig 36: Left: Subjective responses within 15 mins of exiting the scanner (Muthukumaraswamy et al. 2013). Right: Increased global integration in the brain after psilocybin therapy for depression, but not for escitalopram (Daws 2022).

This reduction in overall power is consistent with increased desynchronisation in the signals, as in wave

superposition of decoherent signals, which rise and fall at different instants are more likely to cancel one another, resulting in lower net oscillatory power. This is consistent with diverse interacting signals arising from the stimulatory effects of the psychedelic on usually less associated areas, resulting in more information arising to the conscious level which would normally be filtered out, disrupting the usual flow of attention identifying and streamlining the ordered thought process. The psilocybin study also attempted to identify the source localisation of the resting state networks using independent component analysis (ICA) which determined up to 7, rather than just 1, as illustrated in fig 34(r).

¹⁹ *Synesthesia*: a perceptual phenomenon in which stimulation in one sensory or cognitive mode leads to experiences in a second mode.

Evidence corroborating this interpretation came from a further ingenious experiment from another team led by Carhart-Harris, to analyse “homological scaffolds” of brain activity under psychedelics. Fig 34(e) shows the result, in which there is a far richer network of homological scaffolds in play under psilocybin (right) with the “doors of perception” thrown open than in the normal mental state (left). This technique takes filtered correlations between the time series of the fMRI voxels, forms linkage graphs between each correlated series and then applies algebraic topology using the cliques of three or more to determine and weight the connections. Their evolution over time is also used to show that, while most of the population of psychedelic scaffolds have shorter duration than the fewer number in the placebo state, some psychedelic ones last significantly longer. This is also supported fig 34(s, t), by increased fMRI variance in the hippocampus and anterior cingulate and changes in power spectrum and other measures (Tagliazucchi et al. 2014). A further study (Lord et al. 2019) has explored recurrent BOLD phase-locking patterns (PL states). A similar result 5(i) shows LSD increases global functional connectivity of higher-level integrative cortical and sub-cortical regions (Tagliazucchi et al. 2016).

McNamara (2022) notes how psychedelics may alter the balance between intra and interconnectivity to induce mystical experiences:

Tagliazucchi et al. (2016) utilized fMRI to investigate global and local brain connectivity changes from the resting state following intravenous injection of LSD versus placebo to fifteen healthy volunteers. They found that the DMN, salience and FPN or fronto-parietal executive function network and the thalamus showed increased global connectivity under the drug but decreased within-network integrity. The increase in global connectivity observed under LSD correlated with subjective reports of ego dissolution. The authors suggested that increased cross talk between DMN, salience and FPN, when these individual networks are not functioning normally, could blur boundaries between self and world in such a way as to lead to ego dissolution and mystical experiences.

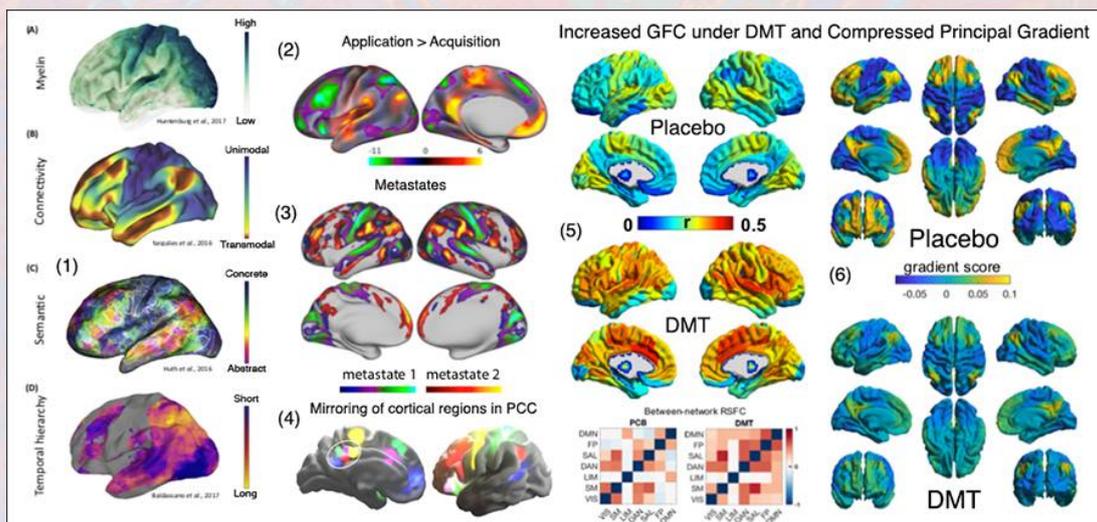

Fig 36b: (1) The principal cortical gradient of the transmodal association cortex pole (or “TOP”) of the human brain, expressed in a variety of measures, forming a hierarchical gradient down to primary sensory areas (Huntenburg et al. 2018). (2) Vatansever et al. (2017) used task-based fMRI to illustrate how the default mode network (DMN) and the fronto-parietal network (FPN), work collectively in cognition to guide complex behaviour. These demonstrate that the FPN is active after a rule change — the “acquisition phase”—suggesting its involvement in encoding the contingencies upon which the decision is based. Later, the “application phase” — when the individual understands the rule, activity within the FPN is reduced, and activity within the DMN increases (Margulies & Smallwood 2017). (3) Vidaurre et al. (2017) show that ongoing states are hierarchically organised, forming temporal groupings referred to as “metastates.” These reflect a dissociation between states anchored by regions of the cortex concerned with constrained neural processing (such as the sensorimotor systems), from those anchored by transmodal regions of the cortex. Spending time in states anchored in transmodal cortex, including those dominated by the DMN, predict better executive control and higher intelligence. (4) Subregions of the posterior cingulate cortex (PCC) within the white ellipse) and how each is functionally connected with (“echoes”) different whole brain intrinsic connectivity networks (shown by colour) (Braga & Leech 2015). The motor cortex has similar subdivisions sampling sensory and cognitive data (Gordon et al. 2023). (5) Timmermann et al. (2023) show increased global functional connectivity (GFC) under DMT, with corresponding decreased resting state between-network segregation in FPN, DMN, salience (SAL) and limbic (LIM). (6) Timmermann et al. (2023), (as well as Girn et al. 2022), show a compressed principal gradient under DMT (as well as LSD and psilocin), consistent with dysregulation of the separation between abstract associative areas and sensory processing.

In a 2023 study to explore the changes induced by the psychedelic DMT on fundamental neurodynamic networks, including the default mode (DMN) and fronto-parietal (FPN), a team led by Robin Carhart-Harris has performed the first experiment combining concurrent fMRI and EEG investigations.

At dosages consistent with the study, they note:

DMT, induces a deeply immersive and radically altered state of consciousness. DMT is thus a useful research tool for probing the neural correlates of conscious experience. Here, fMRI results revealed robust increases in global functional connectivity (GFC), network disintegration and desegregation, and a compression of the principal cortical gradient under DMT. The present findings advance on previous work by confirming a predominant action of DMT – and likely other 5-HT2AR agonist psychedelics – on the brain’s transmodal association pole, i.e., the neurodevelopmentally and evolutionarily recent cortex that is associated with species-specific psychological advancements, and high expression of 5-HT2A receptors.

The transmodal association cortex pole (or “TOP”) of the human brain sits at the upper end of a hierarchical gradient of cortical organisation, while unimodal sensory areas sit at the lower end. The TOP is linked to abstract semantic representations, longer temporal windows of information processing, and is relatively more detached from sensory input, while also appearing later in primate cortical expansion and development. These findings suggest that the subjective effects of psychedelics depend on the dysregulation of the association cortices. Evidence from neuroimaging studies also suggests that this cortical dysregulation may result in the disinhibition of “lower”, evolutionarily and developmentally “earlier” systems such as the limbic system. This also throws light on aspects of the role of the DMN, not just in the resting state, or phenomena of ego loss, but in active situations, in which the FPN plays a role in cogitative planning of solutions, while the DMN takes over once these strategies are established and have become familiar. It is also consistent with the phenomena of a sensory flood, as lower level sensory and perceptual networks become more globally interactive with higher abstract networks involving our entire conception of reality.

Deco et al. (2018) have in a similar vein, combined multimodal imaging (dMRI, fMRI, and PET) in a causal whole- brain model to explain the functional effects of 5-HT2a receptors with LSD in healthy humans. The model identifies the mechanisms for non-linear interactions between the neuronal and neurotransmitter systems. The model identified the causative mechanisms for the non-linear interactions between the neuronal and neurotransmitter system, which are uniquely linked to (1) the underlying anatomical connectivity, (2) the modulation by the specific brain-wide distribution of neurotransmitter receptor density, and (3) the non-linear interactions between the two.

Barrett et al. (2020) found that psilocybin significantly decreased both the amplitude of low frequency fluctuations as well as the variance of BOLD signal in the left and right claustrum. Psilocybin also significantly decreased functional connectivity of the right claustrum with auditory and default mode networks (DMN), increased right claustrum connectivity with the fronto-parietal task control network (FPTC), and decreased left claustrum connectivity with the FPTC. DMN integrity was associated with right-claustrum connectivity with the DMN, while FPTC integrity and modularity were associated with right claustrum and left claustrum connectivity with the FPTC, respectively. This suggests a major role for altered claustrum signalling in psilocybin’s effects as a model for psychedelic action.

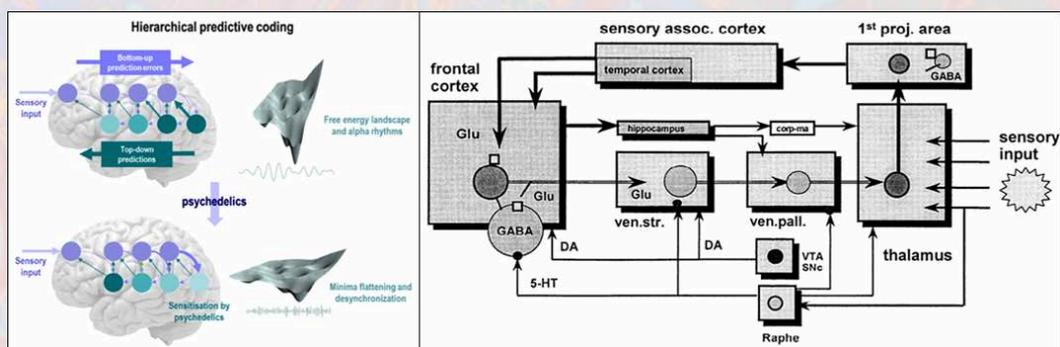

Fig 37: Left: REBUS model of lowered potential energy landscapes causing increased upwelling on psychedelics. Right: CTSC model of thalamic filtering. The filter function of the thalamus, under the control of the CSTC feedback loops, is postulated to protect the cortex from exteroceptive sensory information overload, as well as from internal over-arousal. The model predicts that sensory overload of the cortex may result from thalamic gating deficits, which may be caused by ketamine e.g. by blockade of NMDA-mediated glutamatergic (Glu) cortico-striatal neurotransmission, or excessive stimulation of 5-HT2 receptors—e.g., by psilocybin. James et al. (2022) have also applied Keppler’s (2018) zero point field model of consciousness to ayahuasca and DMT.

A theoretical idea advanced to explain salient features of the brain dynamics in psychedelic experiences is the notion of increased entropy. Carhart-Harris et al. (2014) note that “*There is an emerging view in cognitive neuroscience that the brain self-organizes under normal conditions into transiently stable spatiotemporal configurations that this instability is maximal at a point where the global system is critically poised in a transition zone between order and*

chaos". The paper then goes on to identify "metastability" of a brain network in terms of the variance in the network's intrinsic synchrony over time and to claim the psychedelic state has higher entropy than the normal waking mental state. While the dynamical details of this have been criticised (Papo 2016), they do serve to have conceptual explanatory power. Papo's critique incorrectly pivots on metastability and the argument is squarely refuted by Toker et al. (2022). Edge-of-chaos dynamics and transitions from chaos to order in critically poised sensitive states are essential to a dynamical model of the brain to avoid the dynamics becoming locked into sub-optimal ordered states, by using the butterfly effect and its "ergodic" ability to fully permeate the space of possibilities.

A second model, extending the entropy idea is that psychedelics may act to "flatten the potential energy landscape" between attracting brain states (Carhart-Harris & Friston 2019), which has received some tentative support in an LSD study (Singleton et al. 2021). The 2019 paper notes "*We call this formulation 'relaxed beliefs under psychedelics' (REBUS) and the anarchic brain, founded on the principle that — via their entropic effect on spontaneous cortical activity— psychedelics work to relax the precision of high-level priors or beliefs, thereby liberating bottom-up information flow, particularly via intrinsic sources such as the limbic system.*" SEBUS and ALBUS (strengthened and altered beliefs under psychedelics) are also cited as complementary processes (Saffron 2020).

A distinction is then made between two modes of cognition, **primary consciousness** "*a mode of thinking the mind regresses to under certain conditions, e.g., in response to severe stress, psychedelic drugs and in REM sleep*", including magical thinking, "*a style of cognition in which supernatural interpretations of phenomena are made*" and **secondary consciousness** "*the consciousness of mature adult humans*". The article then takes the view that "*the mind has evolved (via secondary consciousness upheld by the ego) to process the environment as precisely as possible by finessing its representations of the world, so that surprise and uncertainty (i.e., entropy) are minimized.*" It then argues "*that secondary consciousness actually depends on the human brain having developed/evolved a degree of sub-criticality in its functionality, i.e., an extended ability to suppress entropy and thus organize and constrain cognition. It is argued that this entropy-suppressing function of the human brain serves to promote realism, foresight, careful reflection and an ability to recognize and overcome wishful and paranoid fantasies. Equally however, it could be seen as exerting a limiting or narrowing influence on consciousness*". This leads to the conclusion that "*that the underlying neurodynamics of primary states are more "entropic" than secondary states i.e., primary states exhibit more pronounced characteristics of criticality and perhaps supercriticality than normal waking consciousness — implying that the latter is slightly sub-critical, if not perfectly critical.*"

This leads to a discussion of the role the default mode network is claimed to have maintaining the ego through the internal dialogue, leading to forms of mental illness involving the oppression of over-weaning order, such as depression, where repetitious rounds of internal dialogue occur, reinforcing a pessimistic existential outlook. It is also an ongoing feature of the fear of inevitable death that plagues human society.

As noted, there are some major issues with simply using entropy as a measure of criticality (Papo 2016). Highly entropic systems can be products either of chaotic criticality, or noisy randomness and entropy is itself not a measure of either complexity or criticality. That said, the general theme of balancing novelty with uncertainty is characteristic of brain dynamics, much of which has characteristics of pink, or $1/f$ noise displayed by edge-of-chaos dynamics, and human creations such as musical compositions, which ideally balance history and novelty.

A third notion is the cortico–striato–thalamo–cortical (CSTC) model which involves circuits between the cortex and the thalamus that mediate control of sensory information flow to the cortex and awareness and attention (Vollenweider and Geyer, 2001). This model highlights 5-HT_{2a} receptor activation on circuits between the thalamus and cortex to explain the subjective effects of psychedelics (Geyer and Vollenweider, 2008). In this view, psychedelics impede sensory gating functions of the thalamus, allowing increased sensory and interoceptive information flow from thalamus to cortical regions. This reduction in sensory gating is proposed to lead to sensory overload of the cortex that results in both the observed perceptual effects and cognitive changes.

McNamara (2022) in discussion each of these three models notes that none provided a full explanation for the intricate all-revealing nature of psychedelic experiences:

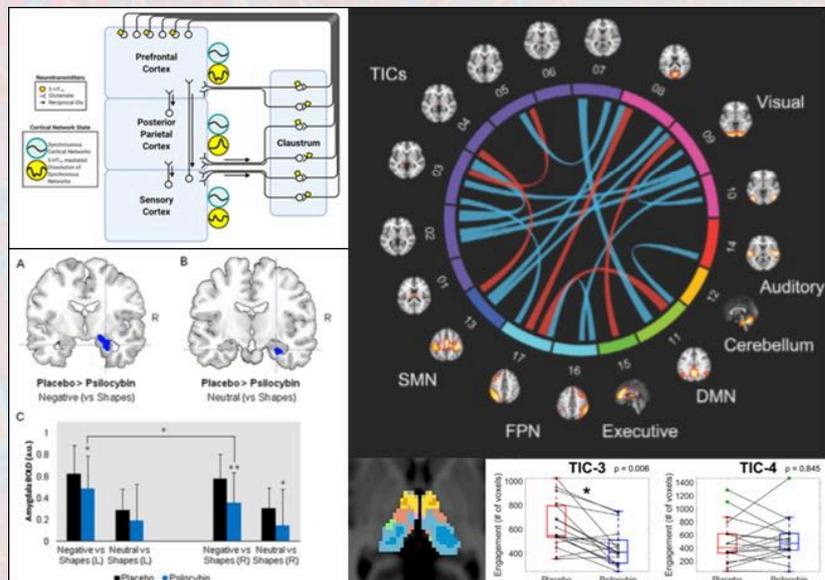

The REBUS model (Carhart-Harris & Friston, 2019) largely relies on the Free Energy Principle (Friston, 2010), which claims that brains seek to reduce uncertainty and do this largely via simulation of expected states or processes. As discussed in previous chapters of this book these simulations of expected events occur at all levels of the neural hierarchy with the topmost node in the hierarchy, the PFC, presumably playing a crucial role in enabling these predictive simulations and processing error messages when simulations do not match up with what actually occurs. The REBUS theory proposes psychedelics disrupt these predictive simulations and error processing essentially by down regulating prefrontal and anterior cingulate cortex "top-down" control of the DMN and by disrupting intrinsic DMN circuits themselves. The precision weighting of prior beliefs is disrupted thus allowing prior expectancies and beliefs to undergo reevaluation. The relaxation of top-down priors allows bottom-up information to exert more influence on brain function,

and this is what underlies the experiences induced by psychedelics. But can a simple increase in impulses or information coming from the bottom (e.g., distal sensory receptors), or even a reduction in filtering information coming from the distal sensory receptors result in the kinds of experiences people undergo on psychedelics? Would not the information simply be a barrage and blur of inchoate sensory experiences unless some kind of higher cortical cognitive processing was intact at the top of the hierarchy during a psychedelic experience? Instead, people report highly structured sensory experiences and indeed full-blown cognitive apperceptions of intricately structured worlds.

The CSTC model is similar in some respects to the REBUS model in that it implicitly adopts the idea that psychedelic experiences basically involve a removal of top-down inhibitory effects or a removal of the filtering functions of executive control networks in the cortex. This model (Vollenweider & Komater, 2010) proposes that psychedelics disrupt the gating functions of the thalamus, so all kinds of information gets into the system, flooding the brain/mind and causing ego dissolution and other psychedelic effects. The loss of gating functions of the thalamus allow increased sensory and interoceptive information to flow from thalamus to cortical regions. While LSD, as noted earlier, does appear to increase thalamus to cortex connectivity, we can ask again whether this information overload is enough to account for the structured experiences we see?

The claustrum-cortical circuit model argues that the claustrum is key to psychedelic drug effects (Nichols, 2016). The claustrum exhibits a large number of 5HT_{2A} receptors and is intensively interconnected with a large number of cortical regions. Therefore, when you perturb the claustrum you demodulate a very large number of cortical networks. Psilocybin alters connectivity between the claustrum and both the default mode and fronto-parietal attention networks in the human brain, but it is not clear exactly how alteration of claustrum activity then alters other brain networks in such a way as to account for the structured experiences we see in psychedelic states.

Fig 37b: (Top-left) claustrum model of psychedelic effects (Doss et al. 2022). (Lower left) reduction in amygdala activity under enhanced positive mood on psilocybin (Kraehenmann et al. 2015). (Right) increases in cortical and thalamic activation over placebo induced by psilocybin (red) and decreases (blue) (Gaddis et al. 2022).

A key characteristic of some neural nets using an energy landscape to reach and optimum is to run the simulation at a higher temperature of random fluctuations at first to avoid the system getting stuck in an “alpine lake”, gradually lowering the temperature to reach a quasi-optimal minimum, in a process called annealing. This is a similar process to using a transition

from chaos to order to enter a quasi-optimal strange attractor. The idea is that the higher energy landscape is a way the brain filters the doors of perception, by impeding upwelling stimuli using top-down control and that when the landscape is flattened using psychedelics, new information can flood into conscious awareness. A core basis of this argument is valid – that the brain has evolved to streamline conscious existence for survival, by filtering out uncertainty to enable rapid and decisive decision-making, ensuring organismic survival, consonant with Aldous Huxley’s (1954) notion in “The Doors of Perception” that everyday reality imposes a filter and that psychedelics, by reducing the filter can enable individual consciousness to perceive the “mind at large”.

Summarising the research to date Drew (2022) has the following overview:

Studies of functional connectivity have shown that the brain contains various discrete networks. Most scientists think there are about seven or eight discrete networks, including an attention or salience network, with others related to vision, hearing, sensorimotor processing and executive control. When a person is at ease, activity is seen across a collection of areas called the default mode network (DMN).

In many studies, the researchers have tried to identify specific connectional changes that correlated well with the self-reported intensity of the trip, or with some particular aspect of it, such as a sense of ego dissolution. These indicate that psychedelics lead to “more connections between networks, and less connectivity within networks.” Brain areas that usually have strong functional connections — and operate in a network that has a fairly circumscribed function — become less connected, suggesting that the drugs disrupt those networks’ normal outputs. And brain areas whose activity is normally only weakly correlated become more

connected. Most findings are consistent with the brain's sensory areas having more influence on overall brain activity after psychedelics were taken.

Another idea that Carhart-Harris et al.'s [2014] paper on the entropic brain considered was that psychedelics dissolve a person's sense of self by weakening connections within the DMN — an idea that gained traction far beyond the research community. Both hypotheses have been influential, but they have their critics.

"We don't know how large the contribution of the default mode network is, because there are ten other brain networks that are also altered," Katrin Preller says. Similarly, several researchers consider entropy to be too nonspecific.

In 2019, Carhart-Harris proposed the REBUS model and the anarchic brain (where REBUS stands for 'relaxed beliefs under psychedelics'), building on Karl Friston's idea of the brain as a prediction machine that constantly forms models of what it expects to perceive in the world, then tests whether incoming sensory data confirm these models. REBUS proposes that psychedelics weaken the constraints that a person's preexisting beliefs place on their perception of the world and of themselves. Under the influence of psychedelics, sensory inputs and recalled memories are freer to influence the brain and conscious experience.

Girn et al. (2022) found that LSD and psilocybin compress the usual hierarchy of connectivity between sensory and association networks. "These sensory areas — and their bare, concrete processing of the external world — become less separate from the processes conceivably related to our abstract thinking and beliefs," Girn says. "It doesn't fully validate the REBUS model, but it's consistent."

From research began in the 1990s in humans and animal models, Vollenweider proposed the CSTC or thalamic gating model. The thalamus is a brain area that processes and filters sensory information en route to the cortex, regulated by the cortex through axons that express the 5HT_{2A} receptor. Psychedelics seem to interfere with the thalamus's filtering operation, resulting in more sensory signals reaching the cortex. This is proposed to be central to the psychological effects of psychedelics.

In addition to these theories, Doss et al. (2022) claim that fMRI findings suggest a central role for the claustrum, a small subcortical region rich in 5HT_{2A} receptors. Like the thalamus, the claustrum exists in a loop with the cortex.

At its core, the entropic brain hypothesis proposes that the quality of any conscious state depends on the system's entropy measured via key parameters of brain function.

Cieri et al. (2021) note: According to the free energy principle (FEP; Friston et al., 2006) the brain is an open, adaptive, complex system far from equilibrium and as with any adaptive self-organizing biological system in nonequilibrium steady-state with the environment, it must reduce its free energy to resist a natural tendency to disorder (Ashby, 1947; Friston, 2010). They further explain that the neural complexity and brain entropy (BEN) of spontaneous neural activity decreases during states of reduced consciousness. This evidence has been showed in primary consciousness states, such as psychedelic states, under the name of "the entropic brain hypothesis", by contrast with physiological and pathological ageing, where BEN is reduced.

However the free energy principle is inadequate because consciousness existence is not just homeostatic, in terms of autopoiesis. Conscious volition is creative and isn't just homeostatic. But the theory is consistent with Huxley's view of the doors of perception being opened to the "mind at large" through psychedelics, so it does have explanatory value.

What feels like enlightenment from the inside looks like disorder from without. The idea here is that the brain processes impose a filter on the cosmic mind so that it can only behave in a way that serves the immediate survival interests of the organism, which makes it virtually impossible for a human to reach moksha. Then psychedelics paradoxically opening the filters causes ultimate reality at large to flood in. But this doesn't mean that the psychedelic experience is just a load of entropic junk — a kind of false vision. It's not this because the combination of sensory overload and self-annihilation allows the brain dynamic to run free of organismic constraints and respond to the underlying dynamic, closer to a disengaged cosmic phenomenon. From the outside, when we don't know the significance, yes this does look like forms of entropy relative to the organismic constraints.

The emerging picture is that, despite using wide varieties of techniques which are often not directly comparable, there is some support for all of these models, which illustrates how pervasive the psychedelic state is on the generation of conscious experience and serves to underline what a comprehensive transformation of our world view the psychedelic state actually entails, based on the wide distribution of 5HT_{2A} receptors.

As novel studies continue, further findings continue to emerge. Kraehenmann et al. (2015) demonstrate reduction of amygdala activity during enhanced positive mood on psilocybin emphasising the positive aspects of the experience.

Gaddis et al. (2022) showing significant psilocybin-induced alterations in spatial organisation of intra-thalamic components. Increased auditory-sensorimotor-thalamic connectivity is also shared between LSD, MDMA and stimulants (Avram et al. 2022). Barnett et al. (2020) have noted decreased directed functional connectivity in the psychedelic state, while Jobst et al. (2021) noted increased sensitivity to strong perturbations in a whole-brain model of LSD and Olsen et al. (2022 noted) time-varying functional connectivity, associated with plasma psilocin and subjective effects.

Mediano et al. (2024) note that the strongest increases in brain entropy which measures (understood as neural signal diversity), and this effect has been associated with both acute and long-term psychological outcomes, such as personality changes accentuated in the closed eye condition of sensory withdrawal. Furthermore, brain entropy changes measured by LZ complexity, fig 38a, are consistently associated with higher subjective ratings of the psychedelic experience, but this relationship is disrupted when participants are viewing a video—potentially due to a “competition” between external stimuli and endogenous LSD-induced imagery.

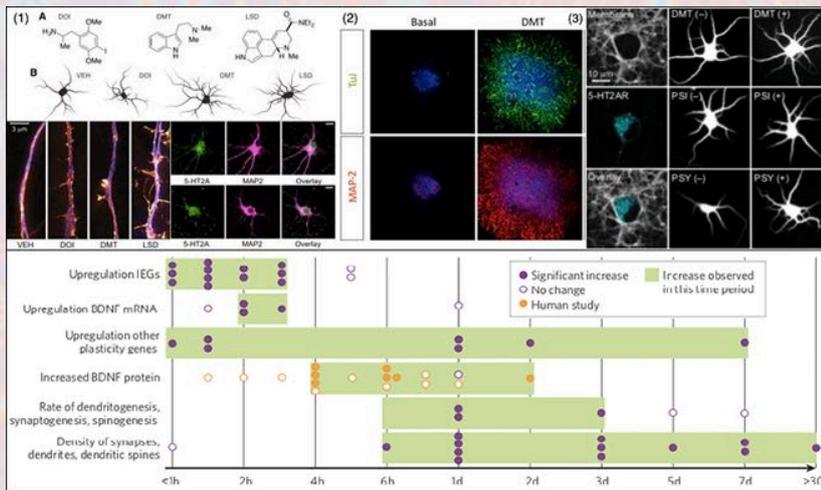

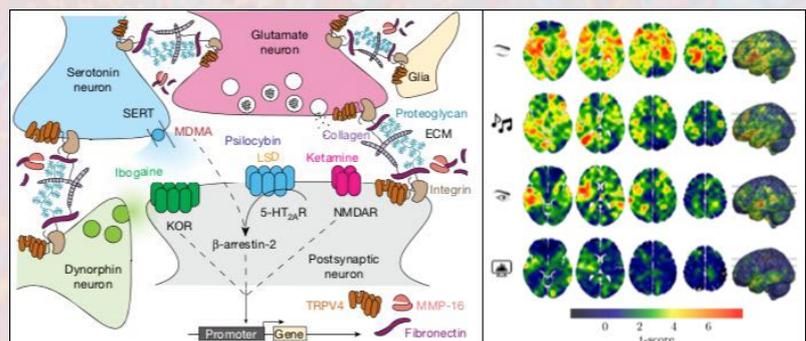

Fig 38: Upper: (1) Changes in neuronal structure, spinogenesis and the involvement of the 5-HT2a receptor in neural plasticity. (2) The involvement of DMT in neurogenesis. Neurospheres were cultured for 7 days in the presence of DMT. (3) Live-cell images of rat embryonic cortical neurons (DIV6) expressing Myc-5-HT2AR-CFP, b2AR-ECFP, or ECFP. Signals from the fluorescent protein and fluorescent plasma membrane marker in cyan and white (Vargas et al. 2023). Widefield images of rat embryonic cortical neurons (DIV6) that were administered compounds DMT, psilocin and psilocybin with (+) and without (-) electroporation, which creates temporary openings in the plasma membrane, which enables highly charged molecules to pass through and access the

intracellular space. The membrane-permeable 5HT2a agonists DMT and psilocin were able to promote dendritogenesis regardless. (Lower) Timeline showing the earliest and latest observations of various changes in neuroplasticity following treatment with a single dose of the serotonergic psychedelics LSD, psilocybin/psilocin, DMT, or DOI. One dot represents one study and time point. Human studies are shown in yellow; animal and in vitro studies are shown in purple. BDNF = brain-derived neurotrophic factor, IEGs = immediate early genes. Based on data for synaptic density, it is assumed that rates of dendritogenesis and synaptogenesis also increase at 6 h post-treatment (Calder & Hasler 2023).

Moliner et al. (2023) show that LSD and psilocin directly bind to TrkB the BDNF receptor promoting neural plasticity, with affinities 1,000-fold higher than those for other antidepressants. -Nardou et al. (2023) have also found that in young mice, psychedelics reopen the social reward learning critical period leading to long-term pro-social behaviour noting that reorganization of the extracellular matrix is a common downstream mechanism underlying psychedelic drug-mediated critical period reopening. There are also hints that psychedelics, such as DMT, which it is also believed occurs naturally to some extent in the brain has neurogenerative effects. Ly et al. (2018) report that, like ketamine, serotonergic psychedelics are capable of robustly increasing neurogenesis and/or spinogenesis both in vitro and in vivo. Calder & Hasler (2023) reinforce this with details of dendritogenesis and neural plasticity.

Fig 38a: (Left) Psychedelics act on a diverse array of principal binding targets and downstream signalling mechanisms that are not limited to the serotonin 2A receptor or β -arr2. Instead, mechanistic convergence occurs at the level of DNA transcription (Nardou et al. 2023). (Right) signal entropy represented by Lempel-Ziv Complexity eyes closed, with music, eyes open and watching TV.

These changes are accompanied by increased synapse number and

function. DMT treatment has also been found to activate the subgranular neurogenic niche regulating the proliferation of neural stem cells, the migration of neuroblasts, and promoting the generation of new neurons in the hippocampus, therefore enhancing adult neurogenesis and improving spatial learning and memory tasks (Morales-Garcia et al. 2020). Increased hippocampal neurogenesis also occurred in mice treated with 0.1 mg/Kg, who also extinguished cued fear conditioning significantly more rapidly (Catlow et al. 2013). Similar plasticity changes have been attributed to all classic psychedelics (Ly et al. 2018, 2021, Sotille et al. 2022. Vargas et al. (2023) further show fig 38(3) that this is common to classic psychedelics and involves intra-neuronal 5HT2a receptors also consistent with the metabotropic findings of fig 34 (b, c, d and u).

6 Therapy and Quantum Change: The Results from Scientific Studies

The theme of ego-dissolution and the DMN is also discussed with Robin Carhart-Harris at length in Michael Pollen's (2018) work. It provides a general perspective in which to understand the basis of some of the outstanding claims about the mental states psychedelics induce. As noted, psychedelics have been found to share characteristics both with meditative states and religious contemplation, in which experimenters have found a reduction in the activity of the DMN. Silencing of the internal dialogue in ego dissolution also involves extensive sensory-existential changes in which the boundary between self and other/world becomes blurred. It is important to understand that dissolving of the DMN in the acute psilocybin phase is naturally followed by a reintegration to an active and more functional DMN than in depressive illness. Carhart-Harris extends this blurring to explaining the magical thinking that frequently leads people experiencing deep insights under psychedelics to describe them as veridically true – revealed truths rather than just a personal opinion. He suggests that one explanation of this is that relative judgment that something is just a personal opinion requires separation of subjectivity to carry weight, but in the state of union no such distinction exists.

This raises a fundamental question. Are the insights real or illusory? This is the same question that plagues the status volitional will. Reductionistic materialists attempt to finesse this position by claiming we are simply the product of our circumstances and the causality of brain processes and that the notion of "free-will" is just an illusion resulting from evolution requiring us to invest in the notion as a rationale to proceed on the basis of an organismic personal autonomy that doesn't actually exist. Subjective consciousness then becomes an epiphenomenon, having no causal effect on the material world. However, most people and the law act on the conviction that we are intentional beings who have consequences on the world around us and that we are accountable for our actions. Premeditation is in criminal law the defining foundation of conscious intent that determines the severity of a crime. We thus need to assess deep psychedelic experiences by the same token. Reports from very astute and trustworthy individuals consistently declare that a genuine veridical experience has taken place, having the nature of truth of the same status as both swearing legal evidence and a replicable observation of the physical world.

Fig 38b: Huxley's reducing valve (Swanson 2018).

Aldous Huxley²⁰ wrote in *The Doors of Perception*: "Each person is at each moment capable of remembering all that has ever happened to him and of perceiving everything that is happening everywhere in the universe. The function of the brain and nervous system is to protect us from being overwhelmed and confused by this mass of largely useless and irrelevant knowledge, by shutting out most of what we should otherwise perceive or remember at any moment, and leaving only that very small and special selection which is likely to be practically useful. According to such a theory, each one of us is potentially *Mind at Large*" ... "In the final stage of egolessness there is an 'obscure knowledge' that All is in all — that All is actually each. This is as near, I take it, as a finite mind can ever come to 'perceiving everything that is happening everywhere in the universe.'"

The word psychedelic means "psyche revealing", where psyche means the human mind, soul, or spirit and *dēlos* means 'clear, manifest'. Thus, Osmond's (1957) proposed name-change— psychedelic—was intended to capture the spirit of filtration theory, by inhibiting certain brain processes which normally maintain their own inhibitory constraints on our perceptions, emotions, thoughts, and sense of self.

Huxley is highly critical of the limiting nature of the doors of perception's usual filter: "To make biological survival possible, *Mind at Large* has to be funnelled through the reducing valve of the brain and nervous system. What comes out at the other end is a measly trickle of the kind of consciousness which will help us to stay alive on the surface of this particular planet. To formulate and express the contents of this reduced awareness, man has invented and endlessly elaborated those symbol-systems and implicit philosophies which we call languages. Every individual is at once the beneficiary and the victim of the linguistic tradition into which he or she has been born — the beneficiary inasmuch as language gives access to he accumulated records of other people's

²⁰ This follows in line with the filter theories of Henri Bergson *Matière et Mémoire* (1896) and William James *Human Immortality*. (1898)

experience, the victim in so far as it confirms him in the belief that reduced awareness is the only awareness and as it be-devils his sense of reality, so that he is all too apt to take his concepts for data, his words for actual things.”

This criticism has become even more urgent and critical in a time of planetary climate and ecocrisis, when this reduced tribal awareness driven by ego-consciousness is causing dire risk of a mass extinction of the diversity of life and potentially the extinction of the human species. To a reader not familiar with these states, it is hard to give credibility to the notion that a person under the influence of an agent originally labelled as an “hallucinogen” that is known to have both transcendent and potentially diabolically dysphoric dimensions as Huxley emphasised in “Heaven and Hell” (1956) can also have experiences with the long-lasting therapeutic relief or mystical insight, let alone be literally and veridically true.

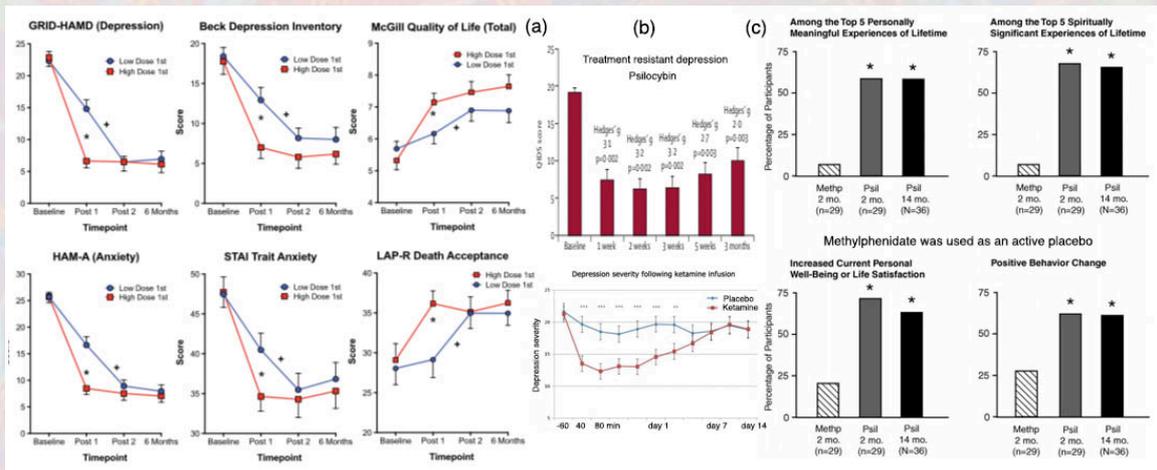

Fig 39: (a) Assessments of improvement in depression, anxiety and quality of life up to 6 months after psilocybin study in subjects facing life-threatening cancer (Griffiths et al. 2016) (b) Improvements in subjects with treatment-resistant depression after psilocybin study (Carhart-Harris et al. 2016b), compared with Ketamine (Zarate et al. 2012). (c) Assessments 2 & 14 months after the psilocybin study Griffiths et al. (2006, 2008). The largest study of its kind (Goodwin et al. 2022) has confirmed these findings for a one-dose treatment for a treatment-resistant episode of major depression.

However this is precisely what a number of studies, where precisely these “revelations” under psychedelics have been repeatedly shown to have long lasting insights and benefits, both in severe depression and in people suffering a terminal condition and in normal people experiencing mystical states (Carhart-Harris et al. 2016b, Griffiths et al. 2006, 2008, 2011, 2016, **2021**, Acero et al. 2023). Studies are also exploring psilocybin use in bipolar disorder (Aaronson et al 2023, Gard et al. 2021, Monaco K 2023, Morton et al. 2023, Yaden et al. 2023). The titles of these research papers indelibly attest to the genuine long-term effects that these experiences induced:

“Psilocybin can occasion mystical-type experiences having substantial and sustained personal meaning and spiritual significance”, “Mystical-type experiences occasioned by psilocybin mediate the attribution of personal meaning and spiritual significance 14 months later”, and “Psilocybin produces substantial and sustained decreases in depression and anxiety in patients with life-threatening cancer”.

The most striking finding from this 14-month follow-up evaluation of the effects of psilocybin ... administered to hallucinogen-naïve volunteers is that a large proportion of volunteers rate their “psilocybin experience” as among the most personally meaningful and spiritually significant of their lives. Fifty-eight percent and 67% of volunteers, respectively, rated the experience as being among the five most personally meaningful experiences of their lives, and the five most spiritually significant experiences of their lives; 11% and 17%, respectively, indicated that it was the single most meaningful experience, and the single most spiritually significant experience. Furthermore, 64% of the volunteers also indicated that the psilocybin experience increased their sense of well-being or life satisfaction moderately or very much, and no volunteer rated the experience as having decreased well-being or life satisfaction.

McNamara (2022) who has become prominent as a researcher into the neurological basis of religious experience strongly confirms the significance of these findings for mystical and religious experience:

It is now very well established that psychedelics reliably produce mystical-like experiences. The first well-documented experimental study to investigate the effects of a serotonergic psychedelic on mystical experience was the so-called Good Friday experiment conducted by Walter Pahnke at Boston University’s Marsh Chapel in 1962. The study involved administration of either 30 mg psilocybin ($n = 10$) or 200 mg nicotinic acid ($n = 10$) to seminary students during the Good Friday religious service (Pahnke, 1967). After the experience, and at a six-month follow-up, participants were assessed for mystical experiences based on the model of mystical experience developed by Stace (1960). The Stace dimensions of mystical experience include sense of unity, sacredness, positive mood, transcendence of time and space, noetic quality, ineffability, paradoxicality, transiency and persisting positive

changes in attitudes and behaviors. Four of the participants in the psilocybin conditions reported most or all of these dimensions while none in the control group did. Doblin (1991) tracked down sixteen of the original twenty participants twenty-five years later and confirmed that many of the positive benefits linked to the psychedelic experience remained!

In a now landmark psychedelic study (Griffiths et al., 2006) using the MEQ, the mean percentage of endorsed items was 78 percent immediately after psilocybin and 33 percent after the control substance methylphenidate. Follow-up some fourteen months later did not substantially change these numbers. In addition, the appearance and intensity of mystical experiences appears to be dose dependent (Barrett et al., 2015; Griffiths et al., 2011): volunteers received 5, 10, 20 and 30 mg/70 kg of psilocybin in separate sessions with at least one month between each session and a placebo session randomly placed within the sequence. The mean percentage of maximum total possible score on the MEQ30 on session days was 23 percent, 47 percent, 52 percent, 70 percent and 77 percent after placebo and 5, 10, 20 and 30 mg/70 kg psilocybin. This score for 30 mg/70 kg at fourteen months was 81 percent. Hierarchical regression analysis demonstrated that MEQ30 scores significantly predicted various clinical, health and spiritual well-being outcomes.

When the people who have them (1) describe the experiences as mystical, religious and spiritual, (2) when these experiences are associated with benign to excellent clinical outcomes, (3) when the phenomenology of the experiences are substantially similar and (4) when the mystical experiences are dose-dependent, I think we can conclude that these experiences are psychedelically induced and genuine religious mystical experiences.

Ketamine has similarly shown promise in treatment-resistant depression, though effects do not last as long as those observed with psilocybin. A possible mechanism has been found in the disassembly of perineuronal nets restraining new synapse formation in established learned memories (Venturino et al. 2021). Other evidence suggests a potentially shared mechanism wherein both ketamine and SPs may engender rapid neuroplastic effects in a glutamatergic activity-dependent manner (Kadriu et al. 2021). The notion due to Craddock, that ketamine and psychedelics share an interaction with microtubules affecting consciousness does not at this point have evidential support.

A later study (Griffiths et al. 2018) combined the use of psilocybin with meditation and other spiritual practices, echoing the way in which movements such as the Native American Church and the Union Vegetale provide a spiritually conducive context to engender positive outcomes, designed to tap into **quantum change experiences** – sudden, distinctive, benevolent, and often profoundly meaningful experiences that are said to result in personal transformations that affect a broad range of personal emotions, cognitions and behaviours (Miller, 2004; Miller and C’de Baca, 2001), also reminiscent of **peak experiences** (Maslow 1964).

The discussion notes: “The study showed robust interactive positive effects of psilocybin dose and added support for spiritual practices on a wide range of longitudinal measures at 6 months including interpersonal closeness, gratitude, life meaning/purpose, forgiveness, death transcendence, daily spiritual experiences, religious faith and coping, and rating of participants by community observers. Analyses suggest that the determinants of these effects were the intensity of the psilocybin occasioned mystical experience and the rates of engagement with meditation and other spiritual practices. Most broadly, as a model system for studying so-called quantum change experiences, which have been described for centuries but which have eluded rigorous prospective experimental analysis, further investigation of psilocybin-occasioned experiences may have broad implications for the development of drug and non-drug interventions in both therapeutic and nontherapeutic applications in order to engender enduring positive trait-level changes in attitudes and behavior and in healthy psychological functioning”.

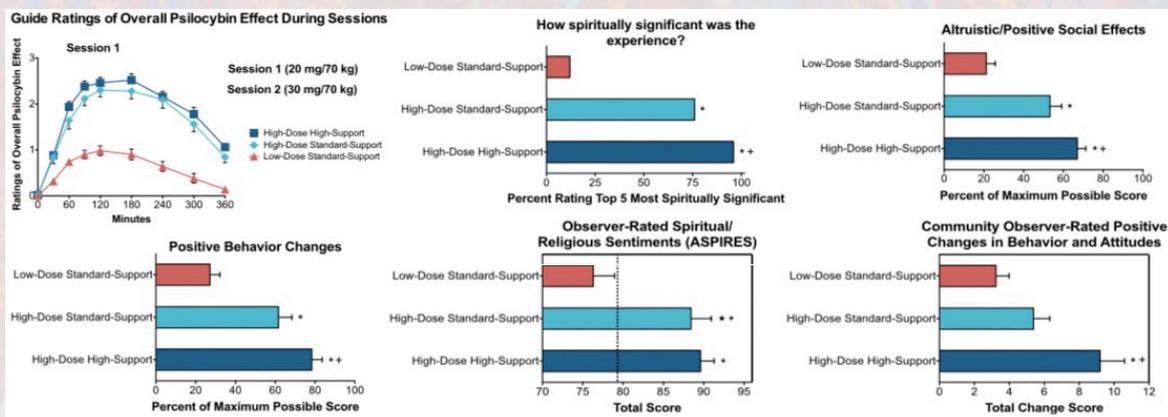

Fig 40: Selected results from Griffiths et al. (2018). All at 6-months after, except for the top-left rating of psilocybin effect.

A further study (Griffiths et al. 2019) compared “God-encounter experiences” under classic psychedelics and naturally. While “the Non-Drug Group was most likely to choose “God” as the best descriptor of that which was encountered while the psychedelic groups were most likely to choose “Ultimate Reality.” Most participants reported vivid memories of the encounter

experience, which frequently involved communication with something having the attributes of being conscious, benevolent, intelligent, sacred, eternal, and all-knowing. ... These experiences were rated as among the most personally meaningful and spiritually significant lifetime experiences, with moderate to strong persisting positive changes in life satisfaction, purpose, and meaning attributed to these experiences". A long-term increase in mindfulness is also noted (Madsen et al. 2020).

Having these mystical experiences, the patient is able to overcome their depression or reframe that depression and return to a more baseline mental being. It really seems to restore ... the wellness and balance in the life of the patient. It's quite magical. We don't know yet, but I strongly suspect that you cannot separate the two [effects therapeutic and psychedelic]. Hallucinating is an essential part of the way these drugs work. Chris Koch chief scientist of the [Allen Institute's MindScope Program](#).

Miller (2004) notes: "The person typically experiences mystical quantum change passively, not a product of personal will or control, and has a difficult time expressing the experience in words. They usually are intensely positive, joyful experiences, and often the person senses the presence of an awe-inspiring transcendent Other. Often there is a noetic element of revelation, a sudden knowing of a new truth. An experience of unity is common; for example, an ineffable oneness with all of humankind, with nature, or the universe. In these respects, the mystical type of quantum change is similar to common reports of near-death experiences (Lorimer 1990). At the most mystical level, quantum changers seemed to become more alike, as if they had in some way glimpsed the same truth. They often voiced the experience of being interconnected with and part of all of humanity and creation. Those who had experienced themselves in the presence of a transcendent Other gave strikingly similar descriptions. They felt awe but rarely fear, for in its presence they had experienced unspeakable love and acceptance. The insightful type of quantum change lacks most of the mystical components save one: the noetic element of sudden realization or knowing with great and sudden force, and in the moment of seeing, the person recognizes them for authentic truth (or Truth). Their effect tends to be a reorganization of one's perceptions of self and reality and a cathartic, ecstatic, sense of relief and release. They knew instantly they had passed through a one-way door through which there was no return. They were changed, freed right then, and knew it immediately. Often, characteristics that had been valued least became most important [spirituality and generosity], and those that had ranked as highest priorities [such as status and possessions] fell to the bottom".

Bill Richards²¹ notes that mystical experience isn't something vague, but a specific form of human consciousness. 'When it's expressed through questionnaires you can find evidence of six categories, which [are]: unity; transcendence of time and space; intuitive knowledge (what William James called the noetic quality); a sense of sacredness or awesomeness; deeply felt positive mood, such as joy, peace, love, purity; and claims of ineffability and what we call paradoxicality — that it's very hard to put these experiences into words and when people try to express it they keep contradicting themselves, that's the paradoxicality: 'I died but I've never been so alive, the ultimate reality was one but it was many, it was beyond time but it included time' — ultimately the Buddhist claim of the nothingness that contains all reality. And it seems contradictory, but mystics would say the problem isn't in the experience; it's in our ability to express the experience within language, at this point in the development of language. And that the answer, the truth is always "both and" rather than "either or"'.

As a warning to unsupported experiences in a bad setting, a survey by Griffiths' group of extreme, challenging experiences (Barrett et al. 2016, Carbonaro et al. 2016), 1993 individuals (mean age 30 yrs; 78% male) completed an online survey about their single most psychologically difficult, or challenging experience (worst "bad trip") after consuming psilocybin mushrooms. 39% rated it among the top five most challenging experiences of his/her lifetime. 11% put self or others at risk of physical harm; factors increasing the likelihood of risk included estimated dose, duration and difficulty of the experience, and absence of physical comfort and social support. 2.6% behaved in a physically aggressive or violent manner and 2.7% received medical help. Of those whose experience occurred >1 year before, 7.6% sought treatment for enduring psychological symptoms. Three cases appeared associated with onset of enduring psychotic symptoms and three cases with attempted suicide. Intriguingly, the degree of difficulty was positively associated with enduring increases in well-being. Despite difficulties, 84% endorsed benefiting from the experience and the researchers noted that the incidence of risky behaviour or enduring psychological distress is extremely low when psilocybin is given in laboratory studies to screened, prepared, and supported participants.

It is extremely significant that facing the fear of immanent death, possibly in pain and debilitation, which is the most real and terrifying crisis any conscious mortal being can face, can be redeemed on an ongoing, not just a transient basis, by a psychedelic experience. This attests to these experiences not being illusory but evidential to the conscious mind as the antidote to the mortal dilemma. This is precisely what "moksha", the primary goal of all Eastern spirituality, seeks to attain through a lifetime of renunciation and devoted meditation. It also stands as highly evidential that in their signature work "The Psychedelic Experience", Leary, Alpert and Metzner (1964) presented a guide for readers to navigate the psychedelic state, framed as a modern representation of the Bardo Thodol or Tibetan Book of the Dead — "The Great Liberation upon Hearing in the Intermediate State" — (Lāma Kazi Dawa-Samdub Eng trans 1927), the Tibetan Buddhist manual for successfully negotiating death and rebirth.

²¹ Bob Jesse and Bill Richards are co-authors of Roland Griffiths' 2006, 2008 mystical experiences studies.

Michael Pollen notes a conversation with Roland Griffiths, in which, despite being a world renowned academic researcher leading the field, he has to pick his words very carefully: "*The first time I raised [Bob] Jesse's idea of the betterment of well people with Roland Griffiths, he seemed to squirm a bit in his chair and then chose his words with care 'Culturally right now that is a dangerous idea to promote' "*. However Roland later commented "*We're all dealing with death – this is far too valuable to limit to sick people*", afterwards carefully amending it to "*This will be far too valuable to limit to sick people*".

"A Psychedelics Pioneer Takes the Ultimate Trip" Marchese (2023) NYT.

As the founding director of the Johns Hopkins Center for Psychedelic and Consciousness Research, Dr. Roland Griffiths has been a pioneer in investigating the ways in which psychedelics can help treat depression, addiction and, in patients with a life-threatening cancer diagnosis, psychological distress. He has also looked at how the use of psychedelics can produce transformative and long-lasting feelings of human interconnectedness and unity. Griffiths, who is 76, has been diagnosed with Stage 4 metastatic colon cancer, in all likelihood terminal, that has brought forth transcendently positive feelings about existence that he calls the great mystery of consciousness. "We all know that we're terminal," says Griffiths, "So I believe that in principle we shouldn't need this cancer diagnosis to awaken. I'm excited to communicate, to shake the bars and tell people, 'Come on, let's wake up!' "

In spite of the diagnosis, life has been more beautiful, more wonderful than ever. When I first got that diagnosis, because I work out regularly, I watch my diet, I sleep well, this came out of left field. There was this period in which it felt like I was going to wake up and say, "Boy, that was a bummer, a bad dream." But soon I started to contemplate the different psychological states that would be naturally forthcoming: depression, anxiety, denial, anger, or adopting some belief system of religious outcomes, which as a scientist I was not cut out to do. I went through those, exploring what life would be like if I inhabited those reactions, and I quickly concluded that that was not a wise way to live. I have a long-term Vipassana meditation practice and the focus there is on the nature of mind, of consciousness, and one comes to see that thoughts, emotions, are transient. That practice — and some experience with psychedelics — was incredibly useful because what I recognized is that the best way to be with this diagnosis was to practice gratitude for the preciousness of our lives. Grasping for the cure wasn't useful.

After getting the diagnosis, I had no immediate interest in psychedelics. I felt in many respects that I was having a very psychedelic-like experience. There was this awakening, this aliveness, and I hesitated to take a psychedelic because I wondered whether it was going to disrupt that. Then a question arose: Is there something I'm avoiding by not taking a psychedelic? Am I defending against some dark, fearful thing I'm in denial about? Am I papering it over with this story of how great I'm doing and actually I'm scared to death? I thought, Well, this would be an interesting stress test. So I did a session with LSD. First, asking myself, "Is there something I am not dealing with?" The answer came back: "No, the joy you're experiencing is great. This is how it should be." Then I asked a question directly of the cancer: "What are you doing here? I got nothing back. Then I wanted to humanize it, and I said: "I really respect you. I talk about you as a blessing. I have had this astonishing sense of well-being and gratitude, despite everything that's happening, and so I want to thank you. This process, is it going to kill me?" The answer was, "Yes, you will die, but everything is absolutely perfect; there's meaning and purpose to this that goes beyond your understanding, but how you're managing that is exactly how you should manage it." So then I said: "OK, there's purpose and meaning. I'm not ungrateful for the opportunity, but how about giving me more time?" [Laughs.] I got no response to that. But that's OK.

Our first study was in cancer patients. Ironically enough, these were cancer patients who were depressed and anxious because of a life-threatening diagnosis. The findings of that study were profound: A single treatment of psilocybin produced large and enduring decreases in depression and anxiety. I've had some limited experience with psychedelics since then. We've now treated hundreds of participants with psychedelics and before sessions, one of the key things that we teach them is that upon taking a psychedelic, there's going to be an explosion of interior experiences. What we ask them to do is be with those experiences — be interested and curious. You don't have to figure anything out. You're going to have guides, and we're going to create this safety container around you. But here's the trick: These are not necessarily feel-good experiences. People can have experiences in which they feel like they come to this beautiful understanding of who they are and what the world is, but people can also have frightening experiences. The preparation we give for these experiences is to stay with them, be curious and recognize the ephemeral nature of them. If you do that, you're going to find that they change. The metaphor we use is, imagine that you're confronted with the most frightening demon you can imagine. It's made by you, for you, to scare you. I'll say: "There's nothing in consciousness that can hurt you. So what you want to do is be deeply curious and, if anything, approach it." If your natural tendency is to run, it can chase you for the entire session. But if you can see it as an appearance of mind, then you go, "Oh, that's scary, but yeah, I'm going to investigate that."

Fig 40c: Griffiths in one of the psilocybin treatment rooms.

The approach that you're describing is pretty far from the typical mind-set of many doctors, who are working within a framework of curing, fixing, prevention. So if the ultimate goal is to help more otherwise healthy people get safe access to the potential benefits of using psychedelics, which of course would need to be used in a safe setting and supervised by trained experts, wouldn't that require a radical rethinking by medical practitioners about what helping people even means?

Yes, it will. One of the inspirations for the endowment is that it's not aimed at patient populations. Right now, there's money pouring into this area, but that's all going to be patient-related — there's a pathway to medical approval. I do have concerns that we don't replicate the mistakes that occurred in the 1960s, which over-promoted psychedelics' use culturewide. They're so powerful that if misaligned with cultural institutions, they can result in cultural kickback. In the 1960s they became aligned with the antiwar movement and radicalized-youth movement that was terrifying to existing political structures and institutions, and as a consequence, legislation was put up against them, funding dried up. We need to proceed cautiously. It's going to be critically important not to threaten existing cultural institutions. So I've been a proponent of medicalization, because with medicalization, we already have regulatory structures in place. It goes through F.D.A. approval; they're going to set standards to maximize safety by specifying who should be eligible to receive, who is authorized to prescribe, and under what conditions treatment should occur. So I'm cautious, but that's why I'll have the endowment in perpetuity. If we look at the long range, this could be critical to the survival of our species.

It is Griffiths's belief that humanity has developed — and is developing — technologies that could threaten its ongoing survival. He also believes that psychedelic experiences can provide the basis for moral and ethical principles that would lessen the likelihood that humanity will drive itself off a cliff. Because there's something about the nature of these experiences under these certain conditions that produce remarkable experiences of interconnectedness of all things. At the deepest level, if we recognize we're all in this together, then we have the kernel of what I suspect is most religious traditions and impulses and that is realizing that the Golden Rule makes a lot of sense. After we spoke, Griffiths mailed me a medallion embossed with an image of mushrooms and inscribed with the phrase "May you remain aware of awareness."

I've noticed that often when you discuss human consciousness and our awareness of the preciousness of life, you talk about those things as an awe-inspiring "mystery." What do you get out of putting it in those terms? Because consciousness may be a mystery now, but I've read theories that are convincing, to a layperson like me, that thoughts come from emotions and our emotions are one of the body's mechanisms of maintaining homeostasis. Or as far as the awareness that life is precious, I could easily imagine that biophilia has evolutionary advantages. So I don't see why these states of being have to be understood as mysteries. Does it diminish them to see them as explainable?

I can easily inhabit an evolutionary account that explains how we have come to be who we are — with the exception of the question of interiority! Why would evolution waste its precious energy on our having interior experiences at all? I don't get that. To me, it's a very precious mystery, and that mystery, if you want to put it in religious terms, is God. It's the unknowable. It's unfathomable. I don't believe in God as conceptualized within different religious traditions, but the mystery thing is something that strikes me as undeniable. I want everyone to appreciate the joy and wonder of every single moment of their lives. We should be astonished that we are here when we look around at the exquisite wonder and beauty of everything. I think everyone has a sense of that already. It's leaning into that more fully. There is a reason every day to celebrate that we're alive, that we have another day to explore whatever this gift is of being conscious, of being aware, of being aware that we are aware. That's the deep mystery that I keep talking about. That's to be celebrated!

On the question of authenticity, of the psychedelic experience, opinions vary. David Nichols (2011), the Perdue pharmacologist who founded the Hefter Institute to support psychedelic research and synthesised the psilocybin for Griffith's experiments (Nichols, Roseman & Timmermann 2018) said "If it gives them peace, if it helps people to die peacefully with their friends and their family at their side, I don't care if it's real or illusion". But Roland Griffiths acknowledges "authenticity is a scientific question not yet answered — all we have to go by is the phenomenology" — i.e. the quality of personal reports. In response to Michael's "staunchly materialist" world view Roland replied "Okay then, but what about the miracle that we are conscious? Just think about that for a second, that we are aware and that we are aware that we are aware! How unlikely is that?"

Primary consciousness associated with reduction of the internal dialogue and ego-dissolution is not just a question of flawed magical thinking that the mind regresses to, but is shared by psychedelics, meditation and deep religious contemplation, all of which in varying ways seek to calm the internal dialogue, attributed to inhibition of the DMN. Michael Pollen cites a number of themes relating to this, including the undifferentiated inclusive mentality of the child mind advanced by Alison Gopnik who co-hosted a talk with Robin Carhart-Harris (2016), echoing sayings of Yeshua

and Don Jose Matsuwa. Gopnik refers to a wider nuanced “lantern awareness” which becomes a starker “spotlight awareness” of the Cartesian theatre in adulthood, which as we age, becomes more and more locked into habitual routines that have been found successful in the past. It also applies to releasing the inability of the ordered mind to think outside the box and to be creative, as opposed to conservative and analytic consciousness, which is strongly history-based, rather than novelty-based.

McNamara (2022) notes the significance of “entity” experiences under psychedelics, particularly DMT which involve the perceived relationship with other visionary agents, which may take diverse forms from fairies, through monsters, thieranthropes (human-animal sprits), aliens, angels, deities and demons and serpents and their parallel with other forms of religious and mystical visionary experience, several of which are illustrated in figs: 168, 195, 203, 246 & 247:

Supernatural agent (SA) encounters are often a part of religious experiences. Existing reviews (Davis et al., 2020, Griffiths et al., 2019) report that on average greater than 80 percent of people who have taken a psychedelic at moderate to high dosage report encounters with nonnatural or supernatural entities. Survey results from the Davis et al. and Griffiths et al. studies revealed that people who had taken an agent with DMT described the SA encounters they experienced as being just as real as encounters with people when off psychedelics. The most commonly endorsed labels for the SAs they encountered when on DMT were “being” (60 percent), “guide” (43 percent), “spirit” (39 percent), “alien” (39 percent) and “helper” (34 percent). Virtually all respondents reported having had an emotional response to the experience including joy (65 percent), trust (63 percent), surprise (61 percent), love (59 percent), kindness (56 percent), friendship (48 percent) and fear (41 percent). The SA was considered to be a conscious being (96 percent), intelligent (96 percent), benevolent (78 percent), sacred (70 percent) and had agency in the world (54 percent). Most respondents believed that the SA was absolutely real, not hallucinated, with 72 percent believing that the entity continued to exist after their encounter.

These experiences can vary from ecstatic to stressful encounters such as with the “angel of death” but the encounter can result in beneficial experience:

In the Davis et al. (2020) survey study more than two-thirds of respondents (69 percent) endorsed receiving a message, task, mission, purpose or insight into personal issues from the entity encounter. All this speaks to the potential therapeutic benefits of such insights. The individual is receiving highly meaningful information from an awe inspiring source, so the information is taken to heart in a way that could impact therapeutic potential.

These can take the form of a near-death like experience as in my encounter with “Brahman” both as ultimate reality and as an ever-compassionate “entity” in the experience which precipitated this cosmology.

Shannon (2002 p13) notes the multi-modal nature of psychedelic experience extending beyond the superficial senses:

Ayahuasca induces powerful visions as well as hallucinations in all other perceptual modalities. Pronounced non-perceptual cognitive effects are also manifest. These include personal insights, intellectual ideations, affective reactions, and profound spiritual and mystical experiences. Moreover, Ayahuasca introduces those who partake of it to what are experienced as other realities. Those who consume the brew may feel that they are gaining access to new sources of knowledge and that the mysteries and ultimate truths of the universe are being revealed to them. All this is often coupled with what drinkers describe as an encounter with the Divine.

But there are also outstanding differences between psychedelic experiences and meditative and contemplative ones, which are essential to understand and are pivotal to the central enigma of existential cosmology. Meditation seeks to achieve enlightenment by careful top down control, mediated by equanimity, rejection of grasping desires, one-pointed concentration and compassionate emotion. Religious contemplation seeks repose in prayer and devotion. Thus the person involved finds a degree subjective fulfilment, amid acceptance of a spiritual or religious doctrine they are already committed to. Although these experiences of ego dissolution may induce positive outcomes for the individual, they also tend to confirm established beliefs, rather than open the floodgates to new ideas challenging one’s preconceived assumptions. By contrast, psychedelics are liable to induce insights of a novel and existentially challenging nature, such as the somewhat baffling notion of “the mind at large” as a spontaneous discovery.

Psychedelics provide a complex cyclonic perturbation of existential and sentient consciousness, not a simple “enlightenment pill”. Bill Richards notes: *‘The relation of the drug to the experience is not like taking an aspirin to get rid of your headache. What the psychedelic substance ... they all seem to be skeleton keys that open up the mind, that give you an opportunity to explore, but where you go and what happens depends on who you are, kind of who you are, your maturity, your life history, your capacity to be able to choose to trust unconditionally, your feeling of safety, your courage. So much more is involved than just taking the drug.’*

What we are dealing with in psychedelics is a whole constellation of mental states, depending on the circumstances and mind set of the person involved. They can take on visionary aspects of traditional notions such as soul theft and sorcery and invoke complex detailed visions from which the word 'trip' arises, including specific socio-cultural motifs such as snakes and animistic visionary deities. Some of these can be hilarious, others frightening. Some can be profound, others frivolous or meaningless. Some can lead to messianic delusions and others to creative art, musical composition and scientific discoveries. Albert Hoffman has stated that Kary Mullis, who invented the polymerase chain reaction that is now identified to be the core of molecular biology techniques and essential for Covid-19 testing, told him he credited its discovery to his use of LSD in his student days where he synthesised LSD. It was reported that he was actually coming down from a trip when the idea struck him. We are dealing with an agent invoking as many diverse features as existence can provide. The critical issue underlying this retinal carnival of experiences is how it can reveal underlying experiential knowledge difficult or impossible to gain through any other route.

Their political liberalism and nature-relatedness dimensions have been confirmed (Nour et al. 2017, Lyons & Carhart-Harris 2018). Nearly nine hundred participants provided information about their naturalistic psychedelic, cocaine, and alcohol use, and answered questions relating to personality traits of openness and conscientiousness, nature relatedness, – “*I am not separate from nature but part of nature*” – and political attitudes. Participants also rated the degree of ego dissolution experienced during their “most intense” recalled psychedelic experience. Analysis revealed that lifetime psychedelic use (but not lifetime cocaine use or weekly alcohol consumption) positively predicted liberal political views, openness and nature relatedness, and negatively predicted authoritarian political views, after accounting for potential confounding variables. Ego dissolution correlated significantly with these effects.

Psychedelics clearly have political and revolutionary implications that can lay siege to traditional cultural values. It is admitted that the initial wave of repression of psychedelics was political in nature in response to a social movement rejecting the core tenets of a consumer society polarised between materialistic exploitation and religious and sexual conservatism. Fifty three years later, we find ourselves only moderately emerging from a period of repression lasting half a century, still tightly regulated, so as to be applicable only to scientific studies, largely on pathological conditions of depression and terminal illness, or direct scientific inquiry but not for the betterment of sane and healthy people. There is a deep parallel between the Catholic repression of gnostic elements in the Inquisition that arose ultimately from cross fertilisation of ideas during the Crusades, and of the witch hunts against older spiritual beliefs centred around the ancient European Goddess whose practices Christianity replaced and the reaction to the social values emerging from psychedelics in the 1960s.

The same repressive end result as the middle ages Christian repressions of dissent occurred when LSD became popularised and suddenly, because it had not yet become illegal, huge quantities of very pure acid flooded into rock culture, by devoted underground chemists not seeking financial rewards but for the “common good”, celebrated by the Beatles’ “Tomorrow Never Knows” citing Leary’s Bardo Thodol, and “Lucy in the Sky with Diamonds”, while on the East Coast of the US, Timothy Leary was pronouncing “turn on, tune in and drop out” and on the West Coast, the Grateful Dead, playing “Dark Star” on acid, the Electric Kool-aid Acid tests and the Merry Pranksters, were blowing young peoples minds, while the infectious ethic of free love was shredding conventional sexual morality. This blew the cover on just how seriously the political and revolutionary implications of psychedelics were laying siege to traditional cultural and particularly commercialistic political and religious values.

In a commentary confluent with Symbiotic Existential Cosmology’s gradations of primal subjectivity, Leary said:

*There are as many levels of consciousness as there are anatomical structures in your body for receiving and decoding energy.
The five most important levels of consciousness are sleep, symbol, sense, cellular awareness, and molecular consciousness
(Timothy Leary 1966 Turn on, Tune in and Drop Out)*

Despite the fact that many of these events passed safely without incident, that LSD didn’t split peoples chromosomes, that groups of people hadn’t stared at the sun until they went blind, by the mid-1960s the backlash against the use of LSD and its perceived corrosive effects on the values of the Western middle class resulted in governmental action to restrict the availability of psychedelics by making any use of them illegal. Both LSD and psilocybin were declared “Schedule One” substances. The governors of Nevada and California signed bills into law on May 30, 1966 and the rest of the world followed shortly after, fulfilling the dark ending of Huxley’s (1962) allegory in “Island”, in which the people of Pala consume yellow mushrooms which they call “moksha” to induce visionary states, but are in the end subjected to a military takeover by a neighbouring conservative religious culture. The picture hardened with the case of Charles

Manson. The prosecution contended that, while Manson never directly ordered the murders, his ideology constituted an overt act of conspiracy.

However schedule 1 didn't stop consumption of psychedelics, which have remained an underground transformative staple at music festivals, forming the entheogenic²² counterpoint to MDMA's entactogenic love-in rave party experience. Entheogen (see Ott 1993) is a term that, by its own meaning infers that deity emerges from the sacrament rather than vice versa, confirming the overwhelming impression from this class of agents that they have transcendent dimensions. Stanislav Groff coined the term "holotropic"²³, to cover wholeness seeking in all its forms from experiencing the totality as in the mind at large to peri-natal experiences of a physical rebirth struggle.

But repressive legislation of the war on drugs has still had a mind-numbingly counter-productive effect. People are incarcerated for long periods for simple possession of psychedelics. For four decades they were effectively eliminated from scientific knowledge, or assessment. Society as a whole has had almost no opportunity to figure out what role these profoundly transformative agents have in world culture, despite the fact that the natural entheogens have been used for millennia for spiritual and therapeutic purposes in every culture that has consumed them. This means that the role of entheogens has until subtly in the 21st century, been suppressed entirely by the very world societies that have claimed to be the pillar of scientific enlightenment. At the same time, while psychedelics continue to be used devotedly by an underground network of devoted psychonauts, they tend to be trivialised as mere entertainment. Their potential impact on society's, and the planet's future, remains occluded as an illegal recreational playground of no confirmed value, or significance.

Currently natural psychedelics are used scientifically in research, and particularly into therapy for pathological conditions of depression and terminal illness. They also continue to be used in some settings for religious and spiritual purposes such as Santo Daime, the Union Vegetale and the Native American Church, much as they have for centuries. Finally they are used recreationally as an illegal but sometimes tolerated fringe activity, partly because they are easy to cultivate and almost impossible to eradicate. All of these uses create a gloss on the phenomenon which clouds its full potential. Recreational use tends to trivialise it and reduce it to the pursuit of pleasure. Spiritual and religious use tends to reinforce existing attitudes, from Christian doctrine to tribal sorcery and witchcraft.

Demonstrating just how complex the discourse on sacred mushrooms are, Andy Letcher in "*Mad Thoughts on Mushrooms*" (2007) cites three dominant discourses in a Foucauldian sense: (1) **Psychotic** where hallucinogens are perceived to induce psychosis, (2) **Therapeutic**, where they are seen to have therapeutic value when confined to the clinic, and (3) **Prohibitory** when they escape the clinic and should be suppressed by the full force of the law. In this view the pendulum swung firstly from (1) → (2) → (3) and is now swinging back towards (2) while still remaining a discourse of containment and marginalisation on the part of academics, out of realistic fear of a regulatory backlash.

Running counter to these three dominant discourses are four resistive discourses: (4) **Recreational**, in which breaking the bounds is advocated both for the pleasure these experiences brain and for the pleasure of transgression against the imposed restrictive order; (5) **Psychedelic**, for their ability to reveal or make manifest the hidden dimensions of the self; (6) **Entheogenic**, stemming ultimately from Gordon Wasson's religious experiences on mushrooms in a group conference in which Carl Ruck coined the term, meaning "generating God within," or "becoming God within", and finally; (7) **Panpsychic / Animistic**, that is, they evoke, not theophany but animaphany. Here, mushrooms are not regarded as altering, consciousness but as adjusting what it is possible to perceive, and therefore the spirits and beings occasioned by mushrooms are neither hallucinations nor some aspect of the self, but beneficent discarnate entities with whom the practitioner attempts to forge relationships. They thus tend to evoke states of consciousness in which the consciousness of animals and plants, to other, e.g. spirit entities, or the mind at large, are experienced.

David Luke (2020) also lists a diverse collection of anomalous experiences spanning the transpersonal and psychedelic including (a) synesthesia, (b) extra-dimensional percepts, (c) out-of-body experiences, (d) near death experiences, (e) entity encounters including (mythological beings, chimeras, extraterrestrials, angels and celestial beings, semi-divine beings such as Jesus or Buddha, demons, monsters and beings of death), (f) interspecies communication, (g)

²² *entheogen* – "god (theos) within", is a psychoactive substance that induces alterations in perception, mood, consciousness, cognition, or behaviour for the purposes of engendering spiritual development or otherwise in sacred contexts. (Wikipedia)

²³ *holotropic* "wholeness seeking" – states which aim towards wholeness and the totality of existence – e.g. Brahman-atman.

possession, and (h) telepathy, precognition, clairvoyance and psychokinesis. DMT is particularly prone to spirit images, as illustrated in “Ayahuasca Visions” (Luna & Amaringo 1991). Shaun Smith (2015) notes the contrasting neurotheological view of theistic phenomena being explained through neurobiology with the theoneurological view of Robert Strassman (2001,2014) in which God or deity is able to alter neurobiology through “the spirit molecule” DMT. Not all of the examples cited by Luke are psychedelic induced and several of the psychedelic examples echo in greater intensity and embellishment those in dreaming and hypnagogic imagery, in which the subject finds themselves immersed in perceived situations and encounters with entities that evaporate with arousal. These can be considered as visions at the periphery of the nierika portal.

At an extreme, we have Terrence McKenna's far-fetched statement identifying mushroom spores, rather than the cosmological consciousness and visions they evoke, as galactic entities of enlightenment spread across the universe:

“I am old, older than thought in your species, which is itself fifty times older than your history. Though I have been on earth for ages, I am from the stars. My home is no one planet, for many worlds scattered through the shining disc of the galaxy have conditions which allow my spores an opportunity for life.” (McKenna 1993 210).

There is a fine line between this kind of statement, which most people will find unbelievable fantasy, and a much more widely held, meaningful and validating discourse that the mushroom experience can evoke a universal consciousness that may inform in meaningful, or even urgent ways, the ensuing direction a person's life needs to take.

Yaden et al. (2021) call for epistemic humility²⁴ regarding psychedelics and the hard problem: *“We conclude by calling for epistemic humility regarding the potential for psychedelic research to aid in explaining the hard problem of consciousness while pointing to ways in which psychedelics may advance the study of many specific aspects of consciousness.”* Epistemic humility is applying a rule that we can't assess reality in itself – the very core of the psychedelic experience of “ultimate reality” unless we do so with the filters of the doors of perception slammed shut! How they can say this, while holding the purse strings of the dominant therapeutic discourse, is extremely troubling.

Their reasoning is not really about psychedelics but about the confounding nature of the hard problem: *“The hard problem of consciousness is currently not scientifically answered, and it is not clear that a scientific answer is even possible, which is why it is called “a hard problem.”* They then note that the hard problem is often described in terms of the “explanatory gap” (Levine, 1983), noting: *“This phrase may be an understatement – there is far more than a gap, but rather a yawning chasm between our current scientific understanding and the prospect of explaining the hard problem of consciousness.”* This is the chasm of the psychedelic experience in which materialistic science fails the test because it can't explain conscious volitional will either. To use the term scientific in this way is a contradiction to the meaning of science as a word which embraces knowledge more generally than physical investigation.

Although psychedelics may not of themselves automatically solve the hard problem, the psychedelic experience cited in this article has led to the cosmological description in this article, which does provide a concise solution to the hard problem. The problem is not with psychedelics, but the assumptions of materialism and physicalism of the current dominant fashion in scientific exploration of brain states. This is confirmed by their statement that: *“it is not clear that a scientific answer is even possible”*. This highlights what the author sees as a dangerous development in psychedelic research, where the agent most startlingly evoking subjective changes to experience is being filtered through a materialistic filter by the very academics acting as the mediators of therapeutic use and research into these agents. This looks to be an example of the dominant discourse in therapeutic use being applied by the mediators of the research to undermine both the psychedelic and the unrestrained entheogenic resistive discourses and the validity of psychedelics outside the laboratory as agents of cosmological investigation.

At the opposite extreme, Bernardo Kastrup (2013), proposes analytical idealism as an alternative, the notion that reality is essentially mental and inseparable from mind:

The scientific method allows us to study and model the observable patterns and regularities of nature ... But our ability to model the patterns and regularities of reality tells us little about the underlying nature of things. Mind is the medium of everything that you have ever known, seen, or felt; everything that has ever meant anything to you. Whatever has never fallen within the embrace of your mind, might as well have never existed as far as you are concerned. Your entire life and universe – your parents and the people you love, your first day at school, your first kiss, every time you were sick, the obnoxious boss at work, your dreams and aspirations,

²⁴ **epistemic humility** – a posture of scientific observation rooted in the recognition that (a) knowledge of the world is always interpreted, structured, and filtered by the observer, and (b) scientific pronouncements must be built on the recognition of observation's inability to grasp the world in itself.

your successes, your disappointments, your worldview, etc. – are and have always been phenomena of your mind, existing within its boundaries.

Kastrup (2016, Kastrup & Kelley 2018), has taken the position that psychedelics are precisely what the term indicates – mind manifesting, and sought to contend that psychedelics manifest the idealist principle and that the commentary on the emerging psychedelic research, even by the papers' authors is biased to justify a materialist interpretation of the results. Kastrup cites the research of Carhart-Harris and others showing reductions in activity to be evidence for the basis of "mind-expansion" not being physical in origin, particularly when accompanied by mystical peak experiences and that accompanying research such as the homological scaffolds indicating are of marginal value added to ensure a physicalist interpretation of psychedelic brain states, when the reality of reduced activity indicates they are mind states per se. David Nutt (2023) argues that we don't need to adopt an untestable metaphysical worldview to explain the subjective richness of psychedelic experiences.

The position of Symbiotic Existential Cosmology agrees that conscious experience is primary, but acknowledges that psychedelics are chemical neurotransmitter analogues means that the brain is critically involved in the psychedelic state and that the universe is necessary for the psychedelic state to occur and for our biological survival as well, and that a reduction in default mode activity is consistent with peak experiences, and increasing decoherence of activity correlates both with a reduction in coherent power and with increasing inter-connectivity between brain regions.

Symbiotic Existential Cosmology thus does not conform to the philosophical classification in Yaden et al. (2021) into 3 broad categories: materialist, dualistic, and monistic. Symbiotic Existential Cosmology is a form of interactive complementary aspect monism with is implicitly panpsychic so it is not materialist, but neither is it simple dualism or monism. It is a description based on complementarity, extending the wave-particle complementarity of quantum physics to a cosmological subject-object complementarity in which the two complements cannot be separated in a dualism, just as wave and particle aspects are alternate manifestations of a single quantum identity which cannot be separated, yet it is not monistic because it is a complementarity, not simply a monistic theory of a cosmic mind alone.

Yaden et al. (2021) attempt to justify their conclusion by citing four authors, (Blackmore, 2013; Letheby, 2015; Bayne and Carter, 2018; Johnson, 2020). A viewing of Susan Blackmore's 2020 Tucson talk however makes clear that she considers the debate whether psychedelics reveal new discoveries or merely cause distortions of the psyche will only be revealed by the new wave of psychedelic research which I support. Bayne and Carter do not treat the hard problem as such, but critique the idea of layers of consciousness and the simplistic notion that psychedelics per se invoke a "higher" form of consciousness, or even that what psychedelics do reveal can be classified in terms of one-dimensional layers, with which this article again agrees. In fact the notion of the nierika advanced in this article is more like a cyclonic vortex having a multitude of divergent experiential features, some illusory and some informative, with the centre of the cyclone providing a portal to deeper forms of experience which may have abstract or cosmological value. This is not a linear indexed description and the subjective process of entering such states requires going "deeper into the abyss" of unconstrained consciousness rather than any simplistic view of "higher" conscious states.

Link Swanson (2018) provides a comprehensive review of theories of the psychedelic state, from the first discovery of mescaline, through the psychotomimetic era of researchers experiencing its effects, but using their experiences to treat the experience as a form of reduced control shared by psychopathic states, to filter theories of Huxley and others and then on to more recent theories as outlined above, as well as ones we shall explore in the brain consciousness section such as integrated information theory and Friston's free energy principle:

He notes that Friston's theory can also be interpreted in terms of psychedelics:

In one model of global brain function based on the free-energy principle (Friston, 2010), activity in deep-layer projection neurons encodes top-down inferences about the world. Speculatively, if deep-layer pyramidal cells were to become hyperexcitable during the psychedelic state, information processing would be biased in the direction of inference—such that implicit models of the world become spontaneously manifest—intruding into consciousness without prior invitation from sensory data. This could explain many of the subjective effects of psychedelics (Muthukumaraswamy et al., 2013).

Summing up he sees common threads in these perspectives, in a view that's sees psychedelic research as an "acid test" of grand unified theories of brain function:

The four key features identified in filtration and psychoanalytic accounts from the late 19th and early 20th century continue to operate in 21st-century cognitive neuroscience: (1) psychedelic drugs produce their characteristic diversity of effects because they

perturb adaptive mechanisms which normally constrain perception, emotion, cognition, and self-reference, (2) these adaptive mechanisms can develop pathologies rooted in either too much or too little constraint (3) psychedelic effects appear to share elements with psychotic symptoms because both involve weakened constraints (4) psychedelic drugs are therapeutically useful precisely because they offer a way to temporarily inhibit these adaptive constraints. ... Psychedelic drugs offer a unique way to iteratively develop and test such big-picture explanatory frameworks: these molecules can be used to probe the links between neurochemistry and neural computation across multiple layers of neuroanatomy and phenomenology. Meeting the challenge of predicting and explaining psychedelic drug effects is the ultimate acid test for any unified theory of brain function.

Letheby invokes three descriptions of psychedelic experience: (1) **Yes** – by inducing mystical states of consciousness, psychedelics afford direct knowledge of supernatural, transcendent dimensions of reality (the entheogenic resistive discourse). (2) **No** – since materialism or physicalism is true, there are no transcendent realities, and psychedelics just cause compelling hallucinations or delusions (the dominant hallucinogenic and psychotomimetic discourse). (3) **Neither** – a third view that psychedelics can afford genuine epistemic benefits, even if materialism is true and there is no transcendent reality. Rather than helping us learn new factual information, psychedelics then allow us to understand or appreciate already-known (or otherwise knowable) facts in deep, vivid, affectively and motivationally significant ways. This is again taking a position with implicit dependence on a materialistic viewpoint, while conceding psychedelics may reveal epistemic benefits, so it is confining its own conclusion by its founding assumption of materialism. The symbiotic cosmology is again neither simply an old view, nor is it materialistic. It has resemblances to Upanishadic thought dating back to 700 BC, but it is not a monist theory and is based extensively on detailed investigation of quantum reality, chaotic systems, evolutionary origins of membrane excitability and neuroscience in a novel cosmological description induced by a mushroom experience.

Matt Johnson (2020) , who is both a cited reference and also a co-author of Yaden et al., takes issue with the very concept of consciousness itself as “sloppy”, noting that “*one might question whether the different concepts associated with consciousness should even be identified under a singular construct.*” This has some validity, for example the subjectivity of consciousness is distinct from its features of coherent attentiveness and from the distinct nature of specific qualia and with notions of self-consciousness and the cognitive mind of thoughts and verbal processes. But consciousness is all these things in a coherent concept, integral to our existential condition, so “sloppy” is derogatory and unscientific. Consciousness is our most enduring and all-encompassing arena of experience. It is not sloppy! It is fundamental and essential!

In dealing with the hard problem, he says “*Explaining the existence of experience itself, which is the “hard problem” of consciousness, is at present something that appears outside of the realm of empirical science. Some philosophers and scientists have disputed the existence of this hard problem, but I do not think the problem should be dismissed.*” But empiric²⁵ means “experience”, as does experiment, and there is abundant evidence coming also out of the Johns Hopkins team attesting to experiments confirming experiential observations of quantum change involving “ultimate reality” (Griffiths et al. 2018, 2019). These represent statistical evidence, just as the moksha epiphany does. The claims about consciousness and the experiments on mystical states are thus presenting mutually-contradictory academic reasoning. A critique is made of psychedelic states as having no evidential value based on a preamble assessment that the hard problem is empirically unscientific. This contradicts the definition of empirical, whose root lies in subjective accounts, by invalidating veridical reporting. The legal system depends centrally on veridical evidence. It is integral to interrogating the subjective condition sine qua non. So the materialist assumption is empirically counterproductive.

In summing up Johnson states: “*I suggest that psychedelic science has, to date, not provided substantial advancement in our understanding of any of these concepts [easy or hard] purported to relate to consciousness.*” This is a very pessimistic and confounding view for research in psychedelic science that is showing real promise of cultural benefit. Given a priori assumption of the hard problem’s quasi-unscientific status, it is hard to see how substantial advancement could ever occur on either the role of psychedelics as an informant of the nature of reality, or the status of the hard problem itself. This again underlines the fallacy of academic reasoning that is subservient to the materialistic hypothesis to the extent that no other type of cosmology can be entertained and no empirical result can be gained except by objective means. But biogenic/panpsychic cosmology is biologically precise and seamlessly consistent with multiple steps of the evolutionary pathway so it is a meticulous natural description, consistent with quantum and dynamical physics and with neuroscience. Therefore such reasoning is integral to the scientific discourse.

²⁵ **empirical** based on, concerned with, or verifiable by observation or experience rather than theory or pure logic.

Etym. **empiric** via Latin from Greek empeirikos, from empeiria ‘experience’, from empeiros ‘skilled’ (based on peira ‘trial, experiment’).

experimental late 15th century ‘having personal experience’, also ‘experienced, observed’: from Latin experimentum practical experience

This critique of empiricism applies critically to symbiotic cosmology because the principal evidence for it has to come veridically from first person reports. We can't directly see the consciousness of others, so it is impossible to see the consciousness in simpler life forms or physical processes directly. One can rightly conclude that this is the only class of cosmology in which conscious volitional intent is real, so by the veridical test of validity Occam's razor cuts for panpsychism as a necessity. This is because volitional will implies the conscious mind affect the physical brain and hence the physics of the universe. Therefore mind is a complementary aspect of the physical universe. To a materialist this appears to be adding something that is unnecessary but from the veridical perspective it is essential, because materialist cosmology does not admit conscious volitional will. The inescapable solution is quantum panpsychism.

The problem for mechanists is that intervening states of consciousness are largely inaccessible. But organismic consciousness is evident in humans and mammals generally and is accessible also in other forms in deeply unbounded mental states of meditation or psychedelic transcendence, in which organismic consciousness is asymptotically convergent to an unbounded abstract state identifiable to the subject with the mind at large. Thus the two accessible avenues for scientific discovery are the organismic state and the mind at large. This is why the role of psychedelics becomes sine qua non optimal. If you take them out of the equation, you really have only sparse states of meditative vigil and the dreaming state. Thus to discount the importance of psychedelics is futile and counterproductive.

Yaden et al. nevertheless do concede the potentiality of psychedelics to address the hard problem: *"The scientific study of psychedelics and consciousness, in all of its meanings, is still nascent. While we cannot, at present, see any clear scientific traction resulting from the intersection of psychedelics and the hard problem of consciousness, we are open to the possibility of being proven wrong."* This article now of full book length monograph articulates a strategic response.

Moreover several researchers state that the subjective experience of psychedelics, not just their physiological or neurochemical attributes are potentially pivotal in their beneficial effects. Yaden and Griffiths (2020) conclude that:

Based on the results from experimental studies of moderate to high dose psychedelics we believe that the case for subjective effects playing a major role in enduring beneficial effects is compelling. Across a number of studies, when the intensity of the subjective psychedelic effect is controlled, certain subjective effects predict desirable outcomes. Underlying neurobiological mechanisms are likely necessary but not sufficient to confer full and enduring beneficial effects.

Johnson (2022) in reviewing Chris Letheby's "Philosophy of Psychedelics" (2021) concurs with both this viewpoint and the central role of a "naturalism" that leads to a more supernatural worldview that is not just a comforting delusion:

Letheby argues based on the evidence that subjective experience does play a causal role in long-term benefit. This is supported by studies showing that the mystical-type nature of the experience can predict how therapeutic or otherwise positive the sessions will be in the long term, providing information in some cases that is above and beyond the predictive value of the dose itself or the participants' ratings of drug intensity. Letheby posits that the subjective experience causes lasting therapeutic benefit independent of whether the session involved or left patients with supernatural ideation. He argues, successfully in my opinion, that the core mechanism of psychedelic therapy benefit is not the provision of a comforting delusion, for example, one in which people shift to a more supernatural worldview. He argues instead that "naturalism" is the lens through which the key mechanisms of psychedelic therapy can be understood by combining empirical evidence across multiple disciplines through scientific reasoning. ... Letheby believes that changes in self-representation are the missing link connecting mystical experiences to therapeutic outcomes.

Safron & Johnson (2022) examining both present trends and future possibilities, note the relationship between psychedelics and natural dreaming states: *While we agree that some psychedelic experiences may be understood as a transient form of psychosis, we would add that the same thing can be said about dreaming. ... Intriguingly, while the mechanisms of action for both classic and non-classic psychedelics vary, there appear to be multiple pathways for inducing states in involving greater tendencies for imagining novel scenarios under states of more vivid and intense conscious experience, potentially contributing to the phenomenology of a "waking dream." While a detailed exploration is beyond the scope of the present discussion, partially overlapping effects from classic psychedelics, anticholinergic drugs (e.g. tropanes), kappa- receptor agonists (e.g. Salvia divinorum), and NMDA-receptor antagonists (e.g. dextromethorphan, or ketamine) suggest that anything that disrupts global integration processes while maintaining (potentially elevated) consciousness has the potential to induce profoundly altered states, and potentially altered traits.*

They conclude the following about the future of psychedelics as a discovery process in the context of formative quantum change experiences:

While we must continue to seek the most powerful and encompassing models we can find, we must also avoid the temptation of assuming that a single account will be adequate for explaining the diverse range of effects associated with different psychedelics under different sets and settings. Some may suggest that the mystic nature of psychedelic experiences reveal the truth of a perennial religion, and perhaps even the veracity of metaphysical principles that some would consider to be supernatural (Timmermann et al.,

2021). Others might conclude that egoless experiences reveal that selves were illusions all along (Millière et al., 2018; Milliere and Metzinger, 2020), so pointing to the veracity of some schools of Buddhist thought.

In particular Timmermann et al. (2021) cite a move away from physical materialism: *Results revealed significant shifts away from 'physicalist' or 'materialist' views, and towards panpsychism and fatalism, post use. With the exception of fatalism, these changes endured for at least 6 months, and were positively correlated with the extent of past psychedelic-use and improved mental-health outcomes. Path modelling suggested that the belief-shifts were moderated by impressionability at baseline and mediated by perceived emotional synchrony with others during the psychedelic experience.*

On the other hand, Millière et al. (2018) cite a diversity of selfless states in both psychedelic and meditative experiences: *We suggest that there are important phenomenological differences even between conscious states described as experiences of self-loss. As a result, we propose that self-consciousness may be best construed as a multidimensional construct, and that "self-loss," far from being an unequivocal phenomenon, can take several forms. Indeed, various aspects of self-consciousness, including narrative aspects linked to autobiographical memory, self-related thoughts and mental time travel, and embodied aspects rooted in multisensory processes, may be differently affected by psychedelics and meditation practices.*

Milliere and Metzinger, (2020) go further and address the foundational question of the link between subjective consciousness and self-awareness in states of ego-dissolution:

*Let us call the general claim that some basic form of self-consciousness or sense of self is ubiquitous to all conscious experiences, **the Ubiquity Thesis**. For example, the subjective effects of certain psychoactive drugs, and particularly those of classic psychedelic drugs such as LSD, psilocybin, or 5-MeO-DMT, present a special interest for the assessment of the Ubiquity Claim. Indeed, these drugs are known to have dramatic effects on self-consciousness, and some reports even suggest that they might temporarily suppress any form of self-consciousness – a phenomenon known as 'drug-induced ego dissolution' in the scientific literature (Nour & Carhart-Harris, 2017).*

In his article "Being for no-one: psychedelic experience and minimal subjectivity", Chris Letheby (2020) asks whether reports of drug-induced ego dissolution provide us with solid evidence against so-called "subjectivity theories of consciousness", according to which phenomenal consciousness constitutively involves a minimal form of self-awareness or "subjectivity". Letheby argues that the alternative notion that putatively selfless states of consciousness associated with depersonalization might not in fact be phenomenally conscious at all, does not work well for reports of selfless states of consciousness induced by classic psychedelic drugs, particularly potent and fast-acting psychedelics such as DMT and 5-MeO-DMT, because there is little doubt that the relevant states are phenomenally conscious.

Miguel Sebastián (2020) argues that given a proper understanding of a minimal form of self-awareness that he labels "Perspectival First-Person Awareness" (or PFP-awareness), it becomes apparent that even putatively selfless states of consciousness do not entirely lack self-awareness. PFP-awareness is anchored in a non-conceptual, identification-free self-attribution that defines the ultimate origin of the first-person perspective of conscious experience. ... He concentrates on the phenomenology of states induced by psychedelic drugs, meditation and dreams, as they have been claimed to present the biggest threat to the Ubiquity Thesis. First, he argues that although there are good reasons to think that some forms of self-awareness that typically accompany our ordinary experience can be compromised in altered states of consciousness, this does not mean PFP-awareness is absent in these states.

Fig 40b: The PEMM Tristinction (Sjöstedt-Hughes 2023).

Sjöstedt-Hughes (2023) sees psychedelic states as trisecting with both metaphysics and mystical states, noting that psychedelic-induced metaphysical experiences should be integrated and evaluated with recourse to metaphysics in which one sees the potential bridge between reason-based philosophy and practical therapy — with psychedelic-assisted psychotherapy there is the potential and mutually beneficial fusion of philosophy with practical science. Thus we see overall that paradoxically, the psychedelic experience, although being regarded as a highly exotic mental state, also has foundational insights about the universality of both subjective consciousness and self-consciousness.

The thesis in this monograph takes a form of a scientific investigation that sets up a verifiable framework to present a cosmology, consisting of interlocking biogenic, panpsychic and symbiotic aspects, scientifically accounting for the flowering of conscious life in the universe, that has components of discourse (2) that they are therapeutic, (5) that they reveal the self, (6) that they induce moksha and (7) in that this is not a theistic description of reality, but one in which consciousness as we know it is widespread in all eucaryote organisms, and in the mind at large through them, so that the animistic actually has a valid cosmological basis.

The Indigenous Psychedelic Dimension

Kerowen Cornelius (2023) reviewing the ethical implications of the scientific explosion of interest in psychedelics as therapeutic tools, for indigenous communities, who have a long history of sacred and medicinal use, cites Yulia Celidwen's (2023) efforts to form a consortium to address these concerns:

Over thousands of years, Indigenous communities have cultivated relationships with and accumulated knowledge on psychedelics such as psilocybin mushrooms, the Amazonian botanical brew ayahuasca, and the West African shrub iboga. More recently, psychedelics have exploded onto the stage of Western science. Clinical trials of these substances in the past 15 years have produced remarkable results in the treatment of depression, addiction, post-traumatic stress disorder, and end-of-life anxiety. Media buzz has generated a rush to legalize their therapeutic use, catapulting the global psychedelic drugs market from \$3.8 billion in 2020 to an estimated \$11.82 billion by 2029. But both Native and non-Native critics say the industry is ignoring the emotional, cultural, and ecological harms it is causing the Indigenous peoples who originated psychedelic medicine.

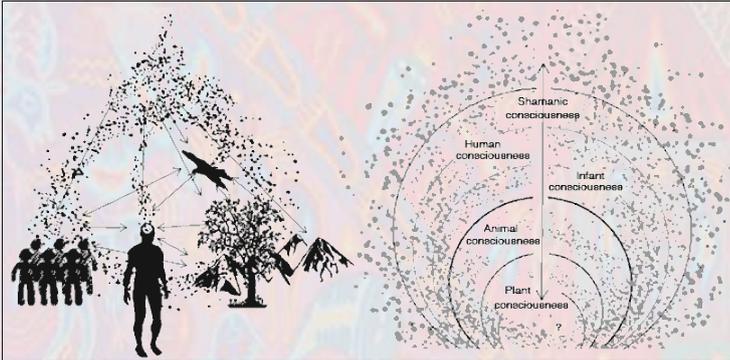

Fig 40c: Indigenous models of consciousness exemplified by animistic individual consciousness as the embodiment of global consciousness and its nested types (Lorencova & Trnka 2023).

Many Indigenous Nations are concerned they are being excluded from psychedelic spaces that extract their knowledge, threaten what they see as their intellectual property, and detach their medicines from their spiritual contexts, the paper finds. In addition, international demand is driving people to unsustainably harvest iboga, the plants used to make ayahuasca, and the hallucinogenic cactus peyote. Meanwhile, burgeoning retreat

*centers that offer psychedelic therapy often charge thousands of dollars for experiences that culturally appropriate Indigenous traditions yet share few benefits with these often impoverished communities. ...The resurgence of Western psychedelic research and practice has led to increasing concerns from many Indigenous Nations regarding cultural appropriation, lack of recognition of the sacred cultural positioning of these medicines, exclusionary practices in research and praxis, and patenting of traditional medicines. Indigenous voices and leadership have been notably absent from the Western psychedelic field currently widely represented by Westerners. An Indigenous-led globally represented group of practitioners, activists, scholars, lawyers, and human rights defenders came together with the purpose of formulating a set of ethical guidelines concerning traditional Indigenous medicines current use in Western psychedelic research and practice. A global Indigenous consensus process of knowledge-gathering was engaged which identified eight interconnected ethical principles, including: **Reverence, Respect, Responsibility, Relevance, Regulation, Reparation, Restoration, and Reconciliation**. A summary of the work is presented here with suggested ethical actions for moving forward within Western psychedelic research and practice spaces.*

The first and foremost of these is reverence for nature and the diversity of life.

Reverence for Mother Nature *Traditional Indigenous medicine is an ethical, ecosystem-protective, and holistic system of medicine that interconnects humans and the environment. A sense of reverence for the planet guides all relationships, as well as a commitment to preserve all life. Traditional Indigenous medicine from a systems and relational perspective prompts insight for compassionate living and awareness of collective care to sustain the well-being of the medicines themselves as well as all future generations.*

Concrete problem *Western psychedelic research and practice has its roots within traditional Indigenous medicines systems yet have turned 'kincentric' approaches (treating all relationships, including medicines, as kin) to anthropocentric approaches (human-centric). This anthropocentric approach fails to adequately reference or acknowledge Indigenous paradigms in Western procedures, thus expropriating Indigenous knowledges while separating the medicines from the context of their original environments.*

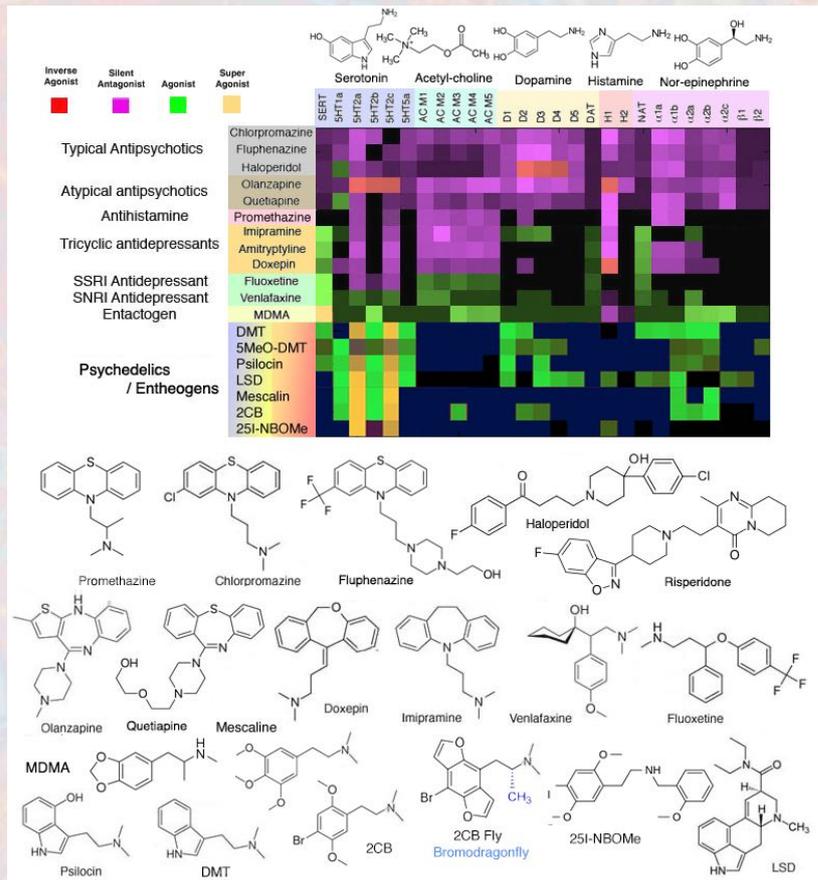

Reverence-governed actions *The explicit acknowledgement of Indigenous Peoples and their traditional medicines and practice as the root of Western psychedelic research and practice; Western psychedelic research and practice references Indigenous concepts of reverence as guided by local Indigenous scholars and communities; the Western psychedelic research and practice community takes action to support Indigenous Nations protection of the at-risk land and natural environments where these traditional Indigenous medicines originate; support Indigenous Peoples in their fulfilment of the right to life and of the right to live in peace on ancestral lands.*

Four later sections in this work – [Psychedelic Agents in Indigenous American Cultures](#), [Shipibo: Split Creations and World Trees](#), [Meso-American Animism and the Huichol](#) and [Redemption of Soma and Sangre in the Sap and the Dew](#), deal in detail with indigenous use as a pivotal heritage of psychedelic knowledge.

The Devil's Keyboard: Sanity, Hallucinations and Visions in the Sappy, Conscious Human Brain

The mammalian brain is not just a seething storm of electrical excitations reverberating through neural networks, but is driven at all stages through the intervening sappy connections that neurotransmitters, neuromodulators and receptors provide between one neuron and the next in the passage of such excitations as they develop strange attractors and other dynamic phenomena of cerebral processing. Neuromodulators do not just affect our moods but are key players in major life decisions. We can better understand these by examining the way psychoactive agents act on many receptors at once, like chords, sequential melodies, or extreme dissonances, enhancing some receptors and depressing the activity of many of others, leading to unpredictable and sometimes uncontrolled consequences and the ways human society, for better or worse, chooses to use these substances to ensure “sanity” or achieve insight.

Fig 41: **The Devil's Keyboard** Plot of receptor binding in pKi of major classes of psychoactive drugs, from antipsychotics through antidepressants and antihistamines to entactogens and entheogens, generated using the PDSP database (<http://pdsp.med.unc.edu/dataMining/pdspConfigGraph.php> and PLoS ONE 5/2 e9019 1-17). Five key classes of modulatory neurotransmitters, serotonin, acetyl-choline, dopamine, histamine and nor-epinephrine, cross indexed against key classes of psychoactive agents – typical and atypical antipsychotics, antihistamines, tricyclic and SSRI, SNRI antidepressants, entactogens, and psychedelics / entheogens. An inverse agonist binds to the same receptor-binding site as an agonist and not only antagonises the effects of an agonist but, moreover, exerts the opposite effect by suppressing spontaneous receptor signalling (when present). If we look across receptors and the various molecules used to alter the flow of these pathways, we begin to gain an understanding of how psychoactive molecules in the sappy biochemical brain activate positively and negatively the “Devil's keyboard” of receptors bound to by these molecules, many of which act on several receptors at once.

Two key primary agents are the amino acid glutamate and the closely related gamma-amino-butyric acid (GABA) which form the excitatory and inhibitory components driving the oscillations of the central pathways for information processing. Both these two are primal amino acids found in the Murchison chondrite and scattered in cosmic gas clouds, so they are not just a quirk of biology. These have both ionopore receptors, which can excite or inhibit electrical oscillations and slower longer-acting metabotropic receptors which modulate overall activity on a contextual basis by signalling to protein pathways interacting with the nucleus and adjacent receptors.

Along with these two, there are several additional simple molecules, many amines, such as dopamine, nor-epinephrine, serotonin (5OH-tryptamine) and complementing them, acetyl choline that, like glutamate and GABA, have an ancient origin as social signalling molecules in single-celled eucaryotes and which also have both ionotropic and metabotropic receptor versions. The amine and choline pathways also form the complementary components of the bodily adrenergic and cholinergic autonomic nervous system. Other receptors have more complex substrates such as the polypeptide endorphins of the opioid receptor.

Antipsychotics – Agents of Darkness

At the negative extreme a dark, diabolical side of psychotherapeutic agents, is presented in the form of antipsychotics. Although an affront to human autonomy, these are admittedly less damaging than a long line of previous diabolical and devastating treatments for key psychotic conditions, from schizophrenia to mania and depression.

The treatment of mental illness has a long tortured history. Lobotomy was one of a series of radical invasive physical therapies that signalled a break with a psychiatric culture of therapeutic nihilism that had prevailed since the late nineteenth-century. The new "heroic" physical therapies devised during this experimental era, including malarial therapy for general paresis of the insane, deep sleep therapy, in which the patients were put into long deep coma, insulin shock therapy, in which patients were repeatedly injected with large doses of insulin in order to produce daily comas over several weeks, cardiazol shock therapy and electroconvulsive therapy, both of which induced seizures, and finally prefrontal lobotomy helped to imbue the then therapeutically moribund and demoralised psychiatric profession with a renewed sense of optimism in the curability of insanity and the potency of their craft at the cost of a complete loss of autonomy and identity by the vulnerable afflicted.

Patients of lobotomy were, immediately following surgery, often stuporous, confused, and incontinent. Some developed an enormous appetite and gained considerable weight. Seizures were another common complication. Emphasis was put on the training of patients. Following the operation, spontaneity, responsiveness, self-awareness, and self-control were reduced. The activity was replaced by inertia, and people were mostly left emotionally blunted and restricted in their intellectual range. Walter Freeman ²⁶described one 29-year-old woman he had operated on as being, following lobotomy, a "smiling, lazy and satisfactory patient with the personality of an oyster" who could not remember her name and endlessly poured coffee from an empty pot. The originator of the procedure, Portuguese neurologist António Moniz, shared the Nobel Prize for Physiology or Medicine of 1949 for the "discovery of the therapeutic value of leucotomy in certain psychoses", which has been the subject of continuing controversy. Lobotomy has become a disparaged procedure, a byword for medical barbarism and an exemplary instance of the medical trampling of patients' rights.

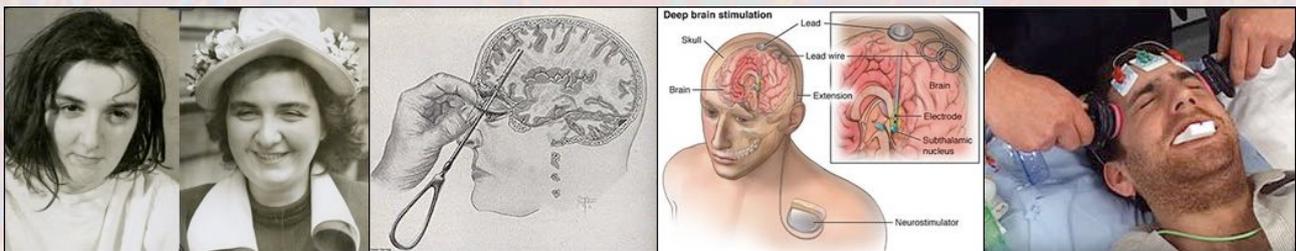

Fig 42: (Left) Freeman stated that this woman was schizophrenic and all that could be done was **to turn her into a 'veritable household pet'**. (Centre) Lobotomy procedure and deep brain stimulation. (Right) Electroconvulsive therapy.

Katie Serena (2022) notes: *Rosemary Kennedy JFK's sister suffered oxygen deprivation during birth. As a child, she was unable to keep up with her siblings. Her lack of inclusion often caused her to experience "fits," which were later discovered to have been seizures or episodes relating to her mental illness. She was also reportedly causing trouble for the nuns in the American convent. According to them, Rosemary was caught sneaking out at night to go to bars, where she met strange men and went home with them. Joe Kennedy was grooming his two oldest boys for careers in politics. Because of this, Rose and Joe worried that Rosemary's behavior could create a bad reputation not just for herself but for the whole family in the future, and eagerly searched for something that would help her. Despite the ominous stories about the lobotomy, Joe needed no convincing to sign Rosemary up for the procedure, as it seemed like this was the Kennedy family's last hope for her to be "cured." Years later, Rose would claim that she had no knowledge of the procedure until it had already happened. No one thought to ask if Rosemary had any thoughts of her own. In 1941, when she was 23 years old, Rosemary Kennedy received a lobotomy. During the procedure, two holes were drilled in her skull, through which small metal spatulas were inserted. The spatulas were used to sever the link between the pre-frontal cortex and the rest of the brain. Though it is not known whether he did so on Rosemary, Dr. Freeman would often insert an icepick through the patient's eye to sever the link, as well as the spatula. Throughout the entire operation, Rosemary was awake, actively speaking with her doctors and even reciting poems to her nurses. The medical staff all knew that the procedure was over when she stopped speaking to them. Immediately after the procedure, the Kennedys realized that something was wrong with their daughter. Not only had the operation failed to cure her intellectual challenges, but it had also left her extremely disabled. Rosemary Kennedy could no longer speak or walk properly. She was moved to an institution and spent months in physical therapy before she regained normal movement, and even then it was only partially in one arm. Her family did not visit her for 20 years while she was shuttered away in the institution. It wasn't until after Joe suffered a massive stroke that Rose went to go see her daughter again. In a panicked rage, Rosemary attacked her mother during their reunion, unable to express herself any other way.*

After 2,500 operations, Freeman performed his final ice-pick lobotomy on a housewife named Helen Mortenson in February 1967. She died of a brain haemorrhage, and Freeman's career was finally over. Freeman sold his home and spent the rest of his days traveling the country in a camper, visiting old patients, trying desperately to prove that his procedure had transformed thousands of lives for the better. Freeman died of cancer in 1972.

²⁶ The father of the Walter Freeman who proposed strange attractors in brain states fig 78.

Deep brain stimulation is an invasive process to surgically insert a stimulating electrode into deep brain regions such as the striatum, nucleus accumbens, subcallosal cingulate and thalamus (Delaloye & Holtzheimer 2014), using an implanted device to marginally help patients with intractable depression, where no other treatment works: A patient notes: *“Things got a little bit easier”*. Participating neurologist Helen Mayberg (Byrne 2023) notes: *“In this process, we are using crude devices, we’re sticking a wire into the brain. I hope I live long enough to see that people won’t require a hole in their brain and a device implanted in this way. I often have a nightmare with my tombstone that kind of reads like, what did she think she was doing?”* 150,000 people in the US have such implants for intractable Parkinsonism. Metzger et al. (2023) and Willett et al. (2023) have developed a brain-computer interface (BCI) enabling a paralysed person to “speak” using an electrode grid over motor areas. Elon Musk (2019) has gained FDA approval for human studies of a BCI, implanted on the cortex (Paul & Singh 2023), which could detect motor signals and could also be used for patterned neuronal stimulation, but recreational use carries surgical risks of brain tissue damage, infection, and scarring and raises acute ethical risks, with cyborg implications²⁷ about the technologisation of human consciousness, as his design for \$2000 entirely robotic brain surgery shows.

By contrast with removing key and essential parts of the brain, or damaging deep implants, electroconvulsive therapy is an electrically disruptive psychiatric treatment where a generalised seizure is electrically induced to manage refractory mental disorders. Typically, 70 to 120 volts are applied externally to the patient's head. ECT is used, where possible with informed consent, as an intervention for resistant major depressive disorder, schizophrenia, treatment-resistant catatonia, prolonged or severe mania. A course involves multiple administrations, two or three times a week until the patient no longer has symptoms. Although it is claimed to be an effective treatment for depression, significant cognitive impairment occurs after ECT. The American Psychiatric Association acknowledges: *“In some patients the recovery from retrograde amnesia will be incomplete, and evidence has shown that ECT can result in persistent or permanent memory loss”*, although it is disputed whether it causes permanent brain damage.

Antipsychotics are a class of psychotropic medication primarily used to manage psychosis (including delusions, hallucinations, paranoia or disordered thought), principally in schizophrenia but also in a range of other psychotic disorders, including bipolar disorder, encompassing mania and depression. First-generation (typical) antipsychotics were introduced in the 1950s following on from the discovery of promethazine in the 1940s, which also has antipsychotic properties but is used as a first generation sedative antihistamine. Chlorpromazine, derived from promethazine originally as a sedative, was found to have neuroleptic properties in the early 1950s, and was the first typical antipsychotic. Second-generation (atypical) antipsychotics, were sought in the 1970s to address some of the side effects including mortality risk.

Research has shown that use of any antipsychotic is associated with smaller brain tissue volumes, including white matter reduction and that this brain shrinkage is dose dependent and time dependent. They may result in many unwanted side effects such as involuntary movement disorders, such as tardive dyskinesia, gynecomastia, impotence, weight gain and metabolic syndrome increasing the risk of heart disease, stroke and type 2 diabetes.

To understand how antipsychotics affect receptors in the brain, it is highly informative to examine in detail their receptor binding properties to the major classes of psychoactive receptors. A key core of antipsychotics involves antagonism at dopamine receptors, believed to be driving psychosis. As shown in detail in fig 41, the prototypical antipsychotic chlorpromazine is an antagonist at all five dopamine receptors D1-5. However, it also antagonises multiple serotonin receptors, all muscarinic acetyl-choline receptors M1-5, histamine H1, and all the α -adrenergic receptors for nor-epinephrine. This is an effect like an elephant sitting on the devil’s keyboard, flattening (a) mood (serotonin) (b) alertness (acetyl choline) (c) motivation (dopamine) (d) wakefulness (histamine) and (e) vigilance (nor-epinephrine). Its introduction has been ironically labeled as one of the great advances in the history of psychiatry.

²⁷ Musk has claimed Neuralink’s device could be used for a range of therapeutic uses, to treat conditions like blindness, paralysis, depression. But he has also said that the eventual aim is to create a “general population device” that could connect a user’s mind directly to supercomputers and help humans keep up with artificial intelligence. He has also suggested that the device could eventually extract and store thoughts, as “a backup drive for your non-physical being, your **digital soul**.” A video released in 2021 shows a monkey using the device to play the video game Pong with his mind and another from 2022 appeared to **show** a monkey typing on a computer “telepathically”. In a current statement, a spokesperson for the FDA would only confirm that Neuralink was approved for an investigational device exemption (IDE) – the FDA process that allows a device to be used for clinical studies. The company would need to assemble an institutional review board to approve and monitor the research. The FDA’s approval last week comes after the regulator initially rejected Neuralink’s previous bid for clinical trials in 2022, **citing** “dozens of deficiencies” the company had to address before human testing, according to a report from Reuters. The company has killed more than 1,500 animals since it began experimenting on them in 2018. Employees told the news service the mortality rate has been higher than necessary due to Musk’s gruelling development timeline.

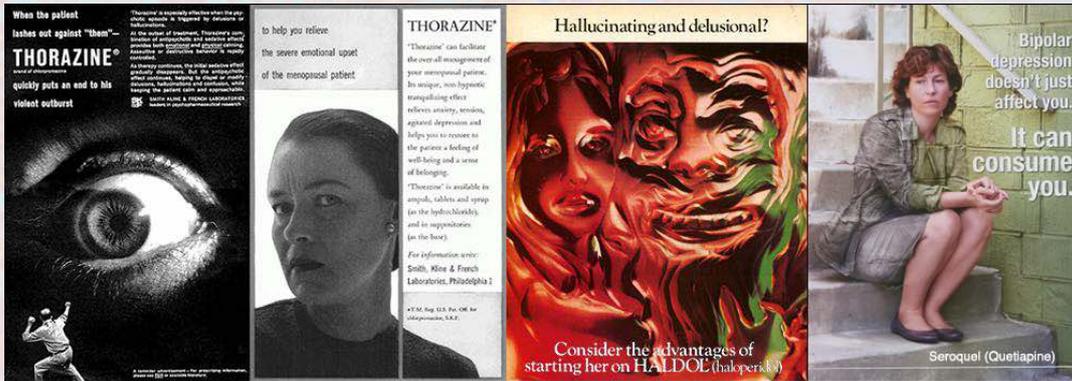

Fig 43: Thorazine (chlorpromazine) advertised both for aggressive mania (in men) “When the patient lashes out against ‘them’—Thorazine quickly puts an end to his violent outburst” and menopausal depression (in women). “To help you relieve the severe emotional upset of the menopausal patient – Thorazine”. Centre Right: “Hallucinating and delusional? – Consider starting her on Haloperidol”. Right: [Quetiapine advert 2009](#). “Bipolar depression doesn’t just affect you – IT CAN CONSUME YOU”. Marketed as both an atypical antipsychotic and as an adjunct treatment for bipolar, or just persistent, depression, complete with five pages of legal disclaimers, including: High blood sugar and diabetes, Weight gain, potentially fatal" neuroleptic malignant syndrome (fever, rigid muscles, confusion), "tardive dyskinesia (TD) uncontrollable movement of the face, tongue, or other parts of the body" which can become permanent, Cataracts, Suicidal thoughts, increased risk of death, "Priapism" [2011 Seroquel TV Advert](#).

Other typical antipsychotics are tuned to enhance the focus on antagonising dopamine receptors. Fluphenazine does this strongly with less anticholinergic effects. It is less prone to causing sedation, or low blood pressure but is associated with a higher frequency of movement disorders. Haloperidol does it even more aggressively, by being an inverse agonist, particularly at D2 as well as D3, D4 (orange squares in fig 41). However this extreme dopamine suppression causes Haloperidol to be the most prone to the rare neuroleptic malignant syndrome, a life-threatening reaction that can occur in response to antipsychotic medication, due to a sudden drop in dopamine levels, paradoxically causing glutamate over-stimulation. *Neuroleptic*, originating from Greek: νεῦρον (*neuron*) and λαμβάνω (*take hold of*)—thus meaning “*which takes the nerve*”—refers to both common neurological effects and side effects. Symptoms include high fever, confusion, rigid muscles, variable blood pressure, sweating, and fast heart rate. Complications include rhabdomyolysis, when damaged muscle tissue releases its proteins into the bloodstream, leading to heart and kidney damage or failure. All antipsychotics cause a significant increase in death rates when used for elderly dementia. In comparison with atypical risperidone, haloperidol was associated with a mortality ratio of 2.14 in one study and in another both typical and atypical (risperidone, olanzapine, quetiapine, and aripiprazole) had ratios of 1.6 against placebo, implying a death rate for haloperidol against placebo of over 3 times higher.

The atypical antipsychotics, perhaps with the exception of risperidone, fare little better, although they were intended to reduce negative side-effects, and display the same warnings about the same spectrum of outcomes. Quetiapine suppresses the same receptors as chlorpromazine and olanzapine is in addition an aggressive inverse agonist for serotonin receptors 5HT_{2a}, b, & c blanking out emotional mood.

Antidepressants – Brave New World

The history of antidepressants is equally chequered. Monoamine oxidase inhibitors (MAOIs) were the first type of antidepressant developed. Monoamine oxidase is a generalised enzyme which clears the brain of any superfluous monoamine transmitters. Use of MAOIs typically requires diet restrictions and avoiding certain other medications because MAOIs can cause dangerously high blood pressure when taken with certain foods or medications, as noted in serotonin syndrome. MAOIs also affect other neurotransmitters in the brain and digestive system, causing additional side effects.

The next generation of anti-depressants were tricyclics. Imipramine, originally investigated as an antipsychotic, was discovered in the early 1950s, and was the first tricyclic antidepressant, along with amitriptyline. As shown in fig 41, they inhibit serotonin uptake, although antagonising 5HT_{2a} and c, and although not suppressing dopamine, are still strongly anticholinergic, sedative antihistamines that suppress α -adrenergic receptors. Common side effects include sleepiness, sudden weight gain, dry mouth, constipation, nausea, and blurry vision, increased risk of suicide in those under the age of 25, mania, urinary retention and a withdrawal syndrome may occur if the dose is rapidly decreased. Tricyclic antipsychotics, antidepressants and antihistamines all have anticholinergic action which has been associated with increases in dementia and mortality (Gray et al. 2015, McMichael et al. 2020) with high use contributing to an approximately 50% increase in both.

Fig 44: Targeting women: (Left) Mother's little helper": Before the current fashion in SSRI antidepressants, benzodiazepines such as valium (diazepam) and serax (oxazepam) were massively marketed to vulnerable women trapped in domestic incarceration until their recreational popularity and withdrawal symptoms became apparent. (Right) Doxepin "Sinequan [sine qua non] helped her save her family life". The Prozac Promise – Confidence, Convenience, Compliance. Zoloft used for the same purpose as serax. Effexor "I got my playfulness back". In another "I got my mummy back"! Petition: Effexor withdrawal Can bring you to your knees!

Subsequent drug development has focussed closely on the serotonin transporter SERT as a way of enhancing mood in a modulated manner. The current round of SSRI and SNRI antidepressants are head and shoulders above the previous ones, although their efficacy and the basis of their action is still debated (Moncrieff et al. 2022, Erritzoe et al. 2022). Serotonin reuptake inhibition of the serotonin transporter SERT is believed to be responsible for their anti-depressant activity, although longer term neurogenesis has also been reported. The SSRI fluoxetine (prozac) and the SNRI venlafaxine (effexor) thus increase serotonin by reducing the reuptake of serotonin by the serotonin SERT transporter. Common side effects are agitation, nausea, digestive upset, loss of appetite and weight loss dizziness, blurred vision, dry mouth, excessive sweating, insomnia or drowsiness, loss of libido (Cox 2024), anorgasmia, erectile dysfunction, dependence and withdrawal symptoms. Severe side effects include increased risk of suicide, mania, and serotonin syndrome. Antidepressant withdrawal syndrome may occur if stopped. Fluoxetine has a less problematic tendency to antidepressant withdrawal syndrome than venlafaxine and can be used as a stepping stone out.

The effectiveness of antidepressants is still only marginal against placebo, or effective psychological support and they come with problems of long-term dependence potentially as serious as with previous use of benzodiazepines such as "mother's little helper" valium was. By comparison psychedelic therapy holds great promise because it doesn't require daily dosing on an indeterminate basis and the transformative nature of the experience can enable the person to reevaluate their life and meaning in the psychedelic context, giving them a new more wholesome accepting perspective on existence, even for people facing terminal conditions. In 2020 around 4000 death in the US were associated with antidepressants.

Reversing the effect of SERT is also believed to be responsible for the serotonin flooding causing the prosocial entactogenic effect of the amphetamine analogue ecstasy, or MDMA (3,4-Methylenedioxy-methamphetamine). The insights of MDMA experiences have proved effective in dealing with intractable conditions such as post-traumatic stress syndrome (PTSD) through a refreshed world view again without having to have daily medication. However MDMA can cause neurological oxidative damage and medium term depletion of SERT transporters, and deaths have been recorded. In Australia 62% of deaths were attributed to drug toxicity (48% multiple drug toxicity and 14% MDMA toxicity alone), and 38% to other causes (predominantly motor vehicle accidents) with MDMA recorded as a contributory factor (Roxburgh & Lappin 2020). The more serious adverse effects include hypertension, hyperthermia, serotonin syndrome, seizures, stroke, hyponatremia and cardiac arrest, involving multiple factors such as dancing in high temperatures in crowded spaces.

Serotonin Super-Agonists – Agents of Illumination and Annihilation

The most positive tolerable therapeutic agents are in the serotonin receptor class, the 5HT_{2a} receptor [fig 43](#), is widely distributed across the cortex, receiving inputs from 5HT_{1a} neurons sending ascending pathways from the basal Raphe nucleus widely across cortical areas, where they couple e.g. to 5HT_{2a} receptors on vertically-aligned pyramidal neurons and affect mood. Serotonin receptors are diverse with types 1 - 7, both excitatory and inhibitory, with 5HT₁ having five subtypes, 5HT₂ three and 5HT₃ being ionotropic.

The super-agonist effect of psychedelics differs from that of both antidepressants and MDMA because it leads instead to the psychedelic state, putatively via exciting a second subcellular G-protein linked pathway modulating the adjacent metabotropic glutamate receptor mGluR2 as illustrated in fig 34(d). It acts primarily as a super-agonist of 5HT2a and 5HT2c but is also a partial agonist of dopamine and nor-epinephrine receptors (green squares) adding motivational drive and vigilance to the experience. LSD has an even broader distribution of activations, giving it the rich quality of experience appreciatively noted by the research chemist Dave Nicholls.

Fig 45: Timothy Leary ([getonthebus](http://getonthebus.com)), Alexander and Anne Shulgin (Alex Gray) and Albert Hofmann (Robert Venosa).

Note however there is also a dark side – overdosing on SSRIs or SNRIs (serotonin norepinephrine reuptake inhibitors), or combining two agents, including a variety of drug combinations from pethidine which is also serotogenic with SSRIs and some psychedelics (mescaline) and monoamine oxidase inhibitors, can cause the potentially fatal condition, serotonin syndrome, involving high body temperature and blood-pressure, agitation, seizures and muscle breakdown.

The natural entheogens, psilocin, DMT and mescaline, are safe and can be highly illuminating, when used in a safe context, as is LSD although extremely potent. Deaths from overdose are unknown and the few deaths to which natural entheogens are attributed are due to accidental misadventure. Maria Sabina, the mushroom benefactress lived to 93 and last time I took peyote with the road man Tellus Goodmorning he was also 93. Mescaline was first isolated and identified in 1897 by Arthur Heffter and first synthesised in 1919 by Ernst Späth. LSD was first synthesised Nov 16, 1938, by Albert Hofmann, but it wasn't until 1963 that Hofmann and Troxler reported the synthesis of psilocybin. Starting from mescaline, which although not a serotonin analogue binds to the 5HT2a receptor in the same way as psilocin and DMT, a series of more potent mescaline analogs has been created (Shulgin 1991), such as 2CB, 2CB-Fly and the super-potent 25I-NBOMe. Psilocin also has several psychedelic analogues (Shulgin 1997).

But there are plain bad psychedelics too. Bromo-DRAGONFLY (BrDF), fig 41, is a very potent hallucinogen, having around one third the potency of LSD and it has an extremely long duration of action, up to several days and is relatively toxic. It can easily be confused with related less potent agents e.g. 2CB-FLY, which is 20x less potent, 2CB or 2CE which is 100 times less potent. Two young adults died after overdosing on BrDF, which they thought was 2C-E, and several others were hospitalised during the same incident. Because they took a dosage appropriate for 2C-E, those who took the drug received, in some cases, 100x the normal dose. Both deaths followed seizures, vomiting blood, and terrifying hallucinations. A 35-year-old male required amputation of the front part of his feet and several fingers on one hand after taking a massive overdose. The compound acted as a long-acting vasoconstrictor, leading to necrosis and gangrene which became apparent several weeks after the overdose occurred. A 22-year-old male from Copenhagen died after ingesting BrDF. His friend described the trip saying, "It was like being dragged to hell and back again. Many times. It is the most evil [thing] I've ever tried. It lasted an eternity."

The lesson for me is to trust natural entheogens. Sacred mushroom species such as *Psilocybe cubensis* have evolved to provide a genetically pure psychedelic experience with no dangerous contaminants. Magic mushrooms are some of the safest recreational drugs around. Out of a survey of more than 12,000 people who did shrooms in 2016, just 0.2 percent said they needed emergency medical care—a rate that was five to six times lower than LSD, cocaine, MDMA, and alcohol, and three times lower than weed. However some wood-loving species *Psilocybe azurescens*, *cyanescens*, and *subaeruginosa* can cause temporary muscle weakness or paralysis.

Cannabinoids

Cannabis plants have a great variety of psychoactive molecules. In particular cannabidiol moderates the effects of the principal psychoactive agent Δ 9-THC to give a more health promoting effect. 11-hydroxy-THC can be formed after consumption of THC from inhalation and oral use, although levels of 11-hydroxy-THC are typically higher when eaten compared to inhalation. The pharmacokinetic equivalency ratio comparing Delta-9-THC with 11-Hydroxy- Δ 9-THC means that one milligram of THC in edible form, is equivalent to 5.71 milligrams of THC in smokable form.

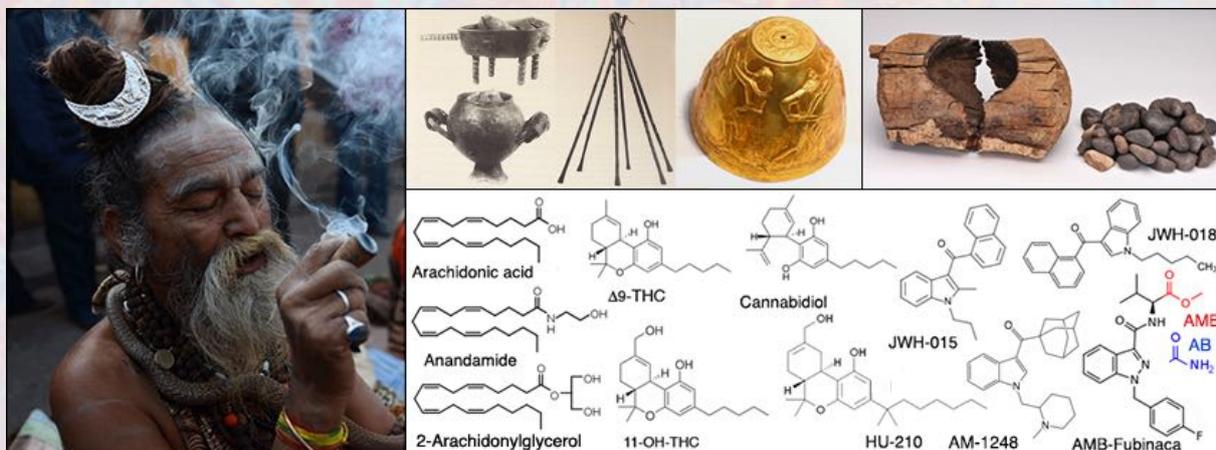

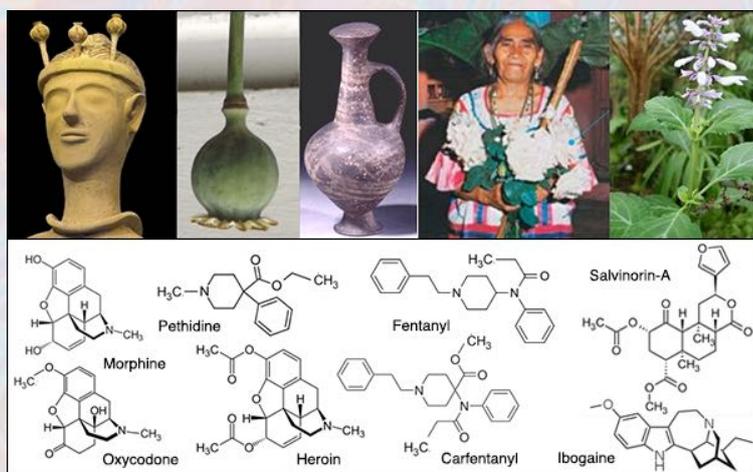

Fig 46:(Left) Sadhu attending the Maha Shivaratri festival Nepal marking a remembrance of "overcoming darkness and ignorance" in life and the world on the night before the new moon. (Lower) Some key natural and synthetic cannabinoids. (Upper-left) Scythians used cannabis ritually by heating whole plants in braziers in an enclosed space (Rudgley 1993). The black residue inside the gold vessels dating from the fourth century BC contained opium and cannabis (Curry 2015). (Upper-right). Vessels for heating cannabis resin of the Sogdians, a people of western China and Tajikistan who were Zoroastrians (Ren 2019). A 700-900 BC Israelite temple with active cannabis is shown in fig 196.

Cannabinoid metabotropic receptors have a variety of functions. CB1 occurs widely in the brain and CB2 is expressed on cells of the immune system where it has an immunomodulatory effect, reducing inflammatory response where it plays a role in processes including implantation of the fertilised embryo. CB1 receptors are thought to be one of the most widely expressed G protein-coupled receptors in the brain. This is due to endocannabinoid-mediated depolarization-induced suppression of inhibition, a very common form of short-term plasticity in which the depolarization of a single neuron induces a reduction in GABA-mediated neurotransmission.

Interference with working memory, displayed by cannabinoids is believed to result from secondary action of glial astrocytes, which have CB1 receptors, on hippocampal pyramidal, cells. The actions of Δ 9-THC result from partial agonist activity at the cannabinoid receptor CB1 ($K_i = 40.7$ nM), located mainly in the central nervous system, and the CB2 receptor ($K_i = 36$ nM), mainly expressed in cells of the immune system, meaning it binds similarly to both.

Anandamide, the principal endocannabinoid, along with 2-arachidonyl-glycerol, both derived from the prominent fatty acid arachidonic acid which occupies 20% of the fatty component of the brain, was first described (and named) in 1992 by Raphael Mechoulam and co-workers. The group went on to devise far more potent synthetic cannabinoids. HU-210, HU for Hebrew University, synthesised by Mechoulam has 100-800 times the potency of THC which itself is active in quantities of around 1-5 mg.

While natural cannabis is a safe herbal product used for up to five thousand years as a psychoactive substance, and the only deaths attributed to natural cannabis use are associated with other factors such as injuries from vehicle accidents

where cannabis is detected, synthetic cannabinoids have exploded on the recreational market, some with serious damaging side effects and deaths.

A series of potent naphthoylindole cannabinoids, the JWH family named after John W. Huffman, of Clemson University introduced a wide array of new cannabinoids with new structural arrangements and some with disquieting side effects. JWH-018 is a full agonist of both the CB1 and CB2 cannabinoid receptors and has been associated with unpleasant effects, including seizures, possibly associated with GABA inhibition and dissociative and anxiety episodes. JWH-073 acts as a partial agonist at both the CB1 and CB2 cannabinoid receptors. It is five times more selective for the CB2 subtype. JWH-015 has an affinity for CB2 receptors of 13.8 nM, while its affinity for CB1 is 383 nM, meaning that it binds almost 28 times more strongly to CB2 than to CB1. JWH-081 by contrast is ten times more selective for CB1. Two fluorinated compounds XLR-11 and AM-2201 have recently been associated with acute kidney damage (Murphy et al).

AB-Fubinaca was originally developed by Pfizer in 2009 as an analgesic medication but was never pursued for human use. In 2012, it was discovered as an ingredient in synthetic cannabinoid blends in Japan. In 2016, a "mass casualty event" in Brooklyn, New York, where 33 people ranging in age from 25 to 59 years old were adversely affected by the drug. 18 were hospitalised. All of the victims were described by bystanders as "zombielike" and the cause was attributed to closely-related AMB-Fubinaca with a methoxy group instead of an amine. A sudden spate of around 60 deaths in New Zealand, which had never experienced deaths from natural cannabis, accompanied by zombie incidents, were also attributed to the drug, with tested products containing between 32 mg/g and 400 mg/g of the active ingredient, between 2x to 25x stronger than the product involved in the mass casualty event in New York a year earlier.

Deleriants – Devil's Breath and Witches Brew

There is a long diverse history of use of solanaceous plants from belladonna (deadly nightshade), henbane and mandrake to *Datura* and *Brugmansia* species to induce states of delirious hallucination in which the subject is unable to differentiate their sometimes mundane hallucinations from reality, becoming unable to look after their own affairs, often slumping into unconsciousness and awakening with little memory of what has happened. This is the basis of the witches' flight on a broom stick, reputedly after rubbing the ointment on their skin and vaginal membranes. It is caused by toxic quantities of scopolamine, which is an indiscriminating muscarinic acetyl-choline antagonist, although also an essential medicine.

Fig 47: *Datura stramonium*, or devil's trumpet, renowned for the Jimson weed incident named after Jamestown, Virginia, where English soldiers consumed it for food while attempting to suppress Bacon's Rebellion. They spent 11 days in altered mental states of hallucinatory delirium incarcerated for their own protection. Guambioano drawing of a woman under a borachero tree of the evil eagle of toxic flight *Brugmansia volcanicola*, or angel's trumpet tree Colombian Andes. The Dance of the Sabbath (Gustav Doré). A young Basque witch applying her flying ointment José de la Pena. *Atropa belladonna* and Henbane *Hyoscyamus niger*. Ceremonial scopolamine use goes back to the beginning of the first millennium BC in the Mediterranean (Guerra-Doce et al. 2023).

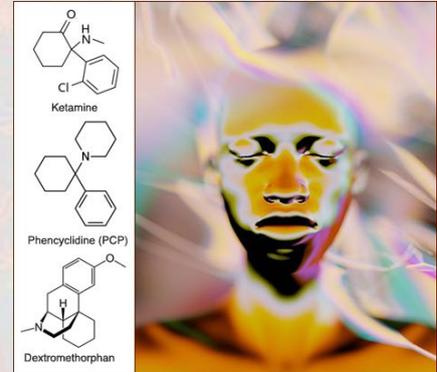

Its use in psychoactive quantities, like that of other anticholinergic agents leads, to accumulating brain atrophy. In smaller doses it is used for motion sickness and postoperative nausea and vomiting. Originally used as an anaesthetic and amnesiac in childbirth, it is frequently used to drug victims to induce docility, persuading the victim to release their bank accounts, after which they awaken not remembering what happened. In South America it is sometimes added to hallucinogenic ayahuasca potions containing DMT.

Then Rachel said to Leah, Give me, I pray thee, of thy son's mandrakes. And she said unto her, Is it a small matter that thou hast taken my husband? and wouldest thou take away my son's mandrakes also? And Rachel said, Therefore he shall lie with thee tonight for thy son's mandrakes (Gen 30:14).

NMDA Dissociatives

Ketamine is a dissociative anaesthetic which induces a trance-like state, providing pain relief, sedation, and amnesia. At sub-anaesthetic doses it is a recreational drug which induces a profound dissociative trance like experience entirely different from psychedelics and is a promising agent for pain and treatment-resistant depression. It is one of the safest anaesthetics, in contrast with opiates, ether, and propofol, it suppresses neither respiration nor heart rate.

Ketamine is an NMDA receptor antagonist which putatively acts by blocking the passage of ions in the ion channel. Related agents are PCP, N₂O, Xenon and dextromethorphan. The psychotropic effects of ketamine range from dissociation and depersonalization. Depending on the setting they can be pleasant or distressing and include a sensation of feeling light, body distortion, absence of time sense, novel experiences of cosmic oneness and out-of-body experiences. PCP has gained notoriety for uncontrolled behaviour, because it stimulates other receptors including D2, notably alleviated in an overdose by Haloperidol's D2 suppression. By contrast, overdosing Ketamine results in falling into the anaesthetic K-hole.

μ -Opioid Analgesics and κ -Opioid Dissociatives

Opioid receptors are a group of inhibitory G protein-coupled receptors with opioid polypeptides as ligands. The endogenous opioids are dynorphins, enkephalins, endorphins, endomorphins and nociceptin. Opioid receptors are distributed widely in the brain, in the spinal cord, on peripheral neurons, and digestive tract. The opioid receptor class consists of four types δ , κ , μ , ζ , and nociceptin – DOR, KOR, MOR, ZOR & NOR. Opiate drugs, such as morphine, act as MOR agonists setting off inhibitory effects, building up tolerance and causing withdrawal symptoms, possibly via NOR. NOP agonists have been shown to act as powerful, non-addictive painkillers in non-human primates. NOP and KOP do not react with MOP agonists such as α -endorphin, the 16 unit polypeptide Tyr-Gly-Gly-Phe-Met-Thr-Ser-Glu-Lys-Ser-Gln-Thr-Pro-Leu-Val-Thr, but dynorphins such as 13 unit dynorphin A – Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Ile-Arg-Pro-Lys-Leu-Lys. The opioid receptors appear to maintain a dynamic equilibrium of pain perception, with opiates effect being due to MOP with NOP contributing to tolerance and withdrawal symptoms, with KOP having an alleviating role.

Fig 48: Top row: Poppy Goddess with slit pods (1400–1100 BC Gazi, Crete), Juglet with traces of papaverine unique to the opium poppy *Papaver somniferum* (Daley 2018), The sacred mushroom benefactress Maria Sabina holding *Salvia divinorum*.

Opium has been revered as a sacred potion since the dawn of urban culture, with sacred use manifest in the slit poppy pods on the crown of the Minoan Goddess and the presence of opium along with cannabis in the Scythian rituals. Opiates remain core essential medicines playing a key role in the management of pain, but they are also prime targets of dependence, addiction and mortality because of their seductive ability to escape the pain of the mortal coil. This leads to opiates and the ensuing synthetic opioids being primary agents of drug-induced mortality.

As can be seen in the figure above, opioids have been developed in two ways, firstly by modification of morphine to heroin (diamorphine), oxycodone and others, and secondly after the discovery of pethidine to arrive at fentanyl and carfentanyl, having exponentiating potencies and risks. The strength of sample opioids relative to morphine is: Codeine 1/10, Pethidine 1/3, Morphine 1, Oxycodone 3/2, Methadone 3, Heroin 3, Fentanyl 100, Carfentanyl 10,000. Correspondingly the overdose death rates in the US for opioids in 2020 are very high and skewed towards the most potent: Heroin 13000, Prescription opioids 16000, Fentanyl 57000. A significant share of these deaths can be directly attributed to the criminal mass marketing of opioids by the US drug industry.

Similarly to μ -opioid receptor agonists, such as morphine, κ -opioid agonists are potently analgesic, and have been employed clinically in the treatment of pain, however they also produce side effects such as dysphoria, hallucinations, and dissociation, which has limited their clinical usefulness. κ -opioid receptors are extremely widely distributed in the brain, spinal cord, and in peripheral tissues, including high levels in the prefrontal cortex, raphe nuclei (dorsal), ventral tegmental area, substantia nigra, dorsal striatum (putamen, caudate), ventral striatum, amygdala, claustrum,

hippocampus, hypothalamus, midline thalamic nuclei, locus coeruleus, spinal trigeminal nucleus, parabrachial nucleus, and solitary nucleus.

They may provide a natural addiction control mechanism, and therefore, drugs that target this receptor may have therapeutic potential in the treatment of addiction. Ibogaine a natural hallucinogen from Africa has seen a wave of popularity as a means to escape addiction and alcohol dependence. There is evidence that distribution and/or function of κ -opioid receptors may differ between sexes. The effects of the κ -opioid agonist salvinorin-A include baffling dysphoric visual spatial experiences quite different from psychedelics, and loss, or inversion of one's body image to become an external part of the environment, like the walls of the room, or crushed between giant wheels in a huge aircraft hangar. As can be seen in fig 34(h), ibogaine's unique receptor binding profile involves super-agonism of 5HT_{2a} providing a psychedelic effect, agonism of κ -opioid receptors providing both alleviation of dependence and a salvinorin-like dissociative effect and antagonism of NMDA receptors, akin to Ketamine's dissociative effect.

Uppers and Downers

Two central drugs of key medical use and recreational and addictive misuse second only to opioids are stimulants, providing euphoriant stimulus and emotional drive, and sedatives, providing obliterating relaxation and somnolence.

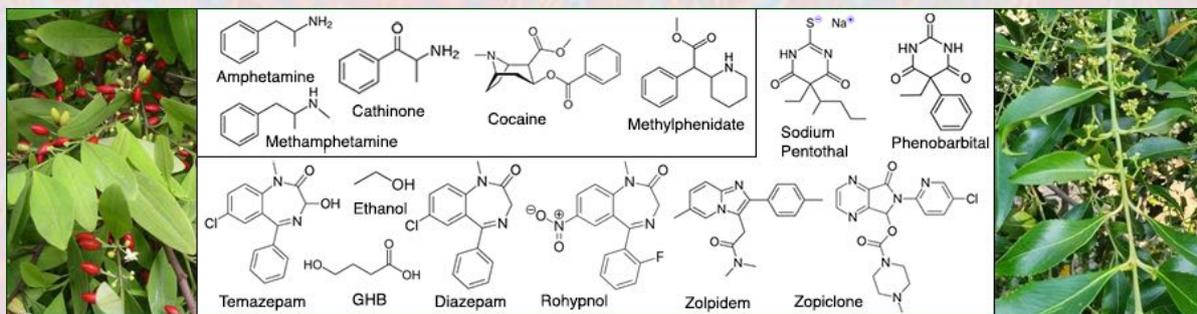

Fig 49: Left: *Erythroxylum coca* providing cocaine. Right: *Catha edulis* (Khat) providing the stimulant cathinone.

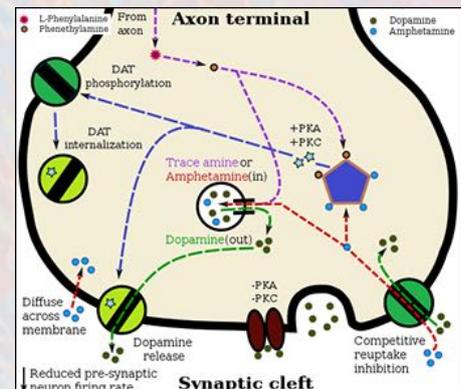

Stimulants

Caffeine, fig 65, present in tea and coffee and multiple plants, is regarded as the world's most commonly used stimulant. It acts uniquely by being an antagonist for receptors for adenosine, which accumulates in the brain through the day in the use of ATP energy, signalling the onset of fatigue.

Other stimulants act to enhance dopamine levels in various ways. Amphetamine is a strong central nervous system (CNS) stimulant that is a potent full agonist of trace amine-associated receptor 1 (TAAR1) residing inside the dopamine secreting synaptic bulb, which plays a key role, in promoting release of dopamine, as part of a complex feedback process, shown in fig 50. Methamphetamine is a variant now used primarily as a recreational drug as a euphoriant that at high doses, can induce psychosis, breakdown of skeletal muscle, seizures and bleeding in the brain. Cathinone is a natural amphetamine analogue consumed widely in the middle East as the stimulant khat.

Fig 50: Amphetamine action inside the synapse to release dopamine.

Cocaine – coca from Quechua kúka, is a natural stimulant from *Erythroxylum* species that has been used for millennia and is ritually and customarily consumed without social harm, by chewing the leaves with lime to free-base it. Cocaine is a purified form of the acid salt that has more capacity for psychological and physical dependence. It binds tightly to the dopamine transporter DAT forming a complex that blocks the transporter's function so that additional dopamine accumulates in the synaptic cleft. Cocaine also blocks the serotonin transporter and norepinephrine transporter, inhibiting reuptake of serotonin and norepinephrine. Effects include intense happiness, sexual arousal, loss of contact with reality, or agitation. Physical effects may include a fast heart rate, sweating, and dilated pupils. Effects begin within seconds to minutes of use and last between five and ninety minutes. Methylphenidate (Ritalin) is also a dopamine and norepinephrine reuptake inhibitor in a 3:1 ratio, used widely for attention deficit syndrome without social harm. A group of cathinone/MDMA analogues, marketed as "bath

salts”, such as mephedrone and methyline are stimulant/entactogen designer drugs with effects similar to MDMA or cocaine, with a duration of 5–6 hours. Methylenedioxypropylvalerone (MDPV) acts as a norepinephrine–dopamine reuptake inhibitor, causing not only a severe anxiogenic effect but also increased aggressive behaviour, resulting in a peak in US emergency admissions in 2011.

Central to the drug wars and the whole criminal enterprise of drug cultivation, manufacture and distribution for illicit profit and second only to opioids as harbingers of mortality, are stimulants. In the US in 2020, overdose deaths from cocaine are estimated at 19,000, and methamphetamine at 24,000. The only viable solution to undercut the cartels is to treat all recreational and nonprescription drug use as a health issue in a decriminalised environment.

Sedatives

Sedatives act almost universally through modulation of ionotropic GABA-A receptors to increase inhibition of ensuing glutamate excitatory activity. GHB (gamma-hydroxybutyric acid) is a pro-drug of GABA that is therefore an indirect natural agonist of GABA_A that causes acute sedation and is sometimes used as a date rape drug. All the other examples cited in the figure are allosteric modulators that result in increased expression of the receptor and central nervous inhibition. Ethanol’s drunkenness and sedation is understood in terms of its activity as such a modulator (Davies 2003).

The first GABA sedatives were the barbiturates that act as central nervous system depressants. They are effective as anxiolytics, hypnotics, and anticonvulsants, but have physical and psychological addiction potential as well as overdose potential and have largely been replaced by benzodiazepines and Z-drugs. Sodium pentothal is a rapid-onset short-acting barbiturate general anaesthetic. It is routinely used for euthanasia and was previously used for most lethal injections in the United States, but the US manufacturer Hospira stopped manufacturing the drug in 2011 and the European Union banned the export of the drug for this purpose. It is still used in some countries as a truth serum to weaken the resolve of a subject and make the individual more compliant to pressure, by decreasing both higher cortical brain function and inhibition. Phenobarbital is used as an anti-seizure medication in epilepsy and occasionally to treat trouble sleeping, anxiety, and drug withdrawal and help with surgery.

The next generation of GABA agents were benzodiazepines, which appeared to present fewer problems of toxicity, dependency and withdrawal. Their effects vary from sedation (temazepam) to tranquillisers aggressively marketed to treat anxiety (diazepam or valium) until recreational use led to a realisation of their dependence and withdrawal risks including rebound insomnia and seizures. Some have a long half life so used for sleep can leave the subject under the influence next day. Non-medical temazepam use reached epidemic proportions in some parts of the world with massive increases in fraudulent prescription, resulting in the banning of its use. Anecdotal evidence suggests that temazepam may be the most psychologically habit-forming (addictive) benzodiazepine.

Flunitrazepam (rohypnol) among other names is used to treat severe insomnia and assist with anaesthesia, to be prescribed only for short-term use or by those with chronic insomnia on an occasional basis. Adverse effects of flunitrazepam include dependency, both physical and psychological; reduced sleep quality resulting in somnolence; and overdose, resulting in excessive sedation, impairment of balance and speech, respiratory depression or coma, and possibly death. Because of the latter, flunitrazepam is commonly used in suicide. It is known to induce anterograde amnesia in sufficient doses; individuals are unable to remember certain events that they experienced while under its influence, particularly dangerous if it is used to aid in the commission of sexual assault. However, in a 2001 study, the benzodiazepines midazolam and temazepam were the two most common benzodiazepines utilised for date rape. In 2020 in the US, benzodiazepines accounted for 12000 deaths by overdose or suicide.

The non-benzodiazepine Z-drugs are also positive allosteric modulators of the GABA-A receptor. Like the benzodiazepines, they exert their effects by binding to and activating the benzodiazepine site of the receptor complex. Many of these compounds are subtype selective, providing novel anxiolytics with little to no hypnotic and amnesiac effects and novel hypnotics with little or no anxiolytic effects. Z-drugs have demonstrated efficacy in treating sleep disorders. There is some limited evidence that suggests that tolerance to Z-drugs is milder and slower to develop than with benzodiazepines. Zolpidem with a short half life of 2-3 hours is reported to result in occasional sleepwalking. Zopiclone has a half-life of 5-7 hours, suitable for inducing and maintaining sleep but without the hangover of temazepam, with a half life of 8-20 hours.

Fractal Biocosmology, Cosmological Panpsychism and Symbiotic Cosmology

Fractal Biocosmology

Fractal biocosmology (King 2020a) is an indisputable empirical feature of the universe, with only one partially unresolved link, in the biogenesis pathway from organic molecules found in galactic gas and dust clouds to the first evidence for life on Earth in rock formations some 3.6 billion years ago, shortly after the oceans formed. Recent research has however filled in many of the gaps in this account, so that there is a high degree of confidence that this stage is also cosmological in nature.

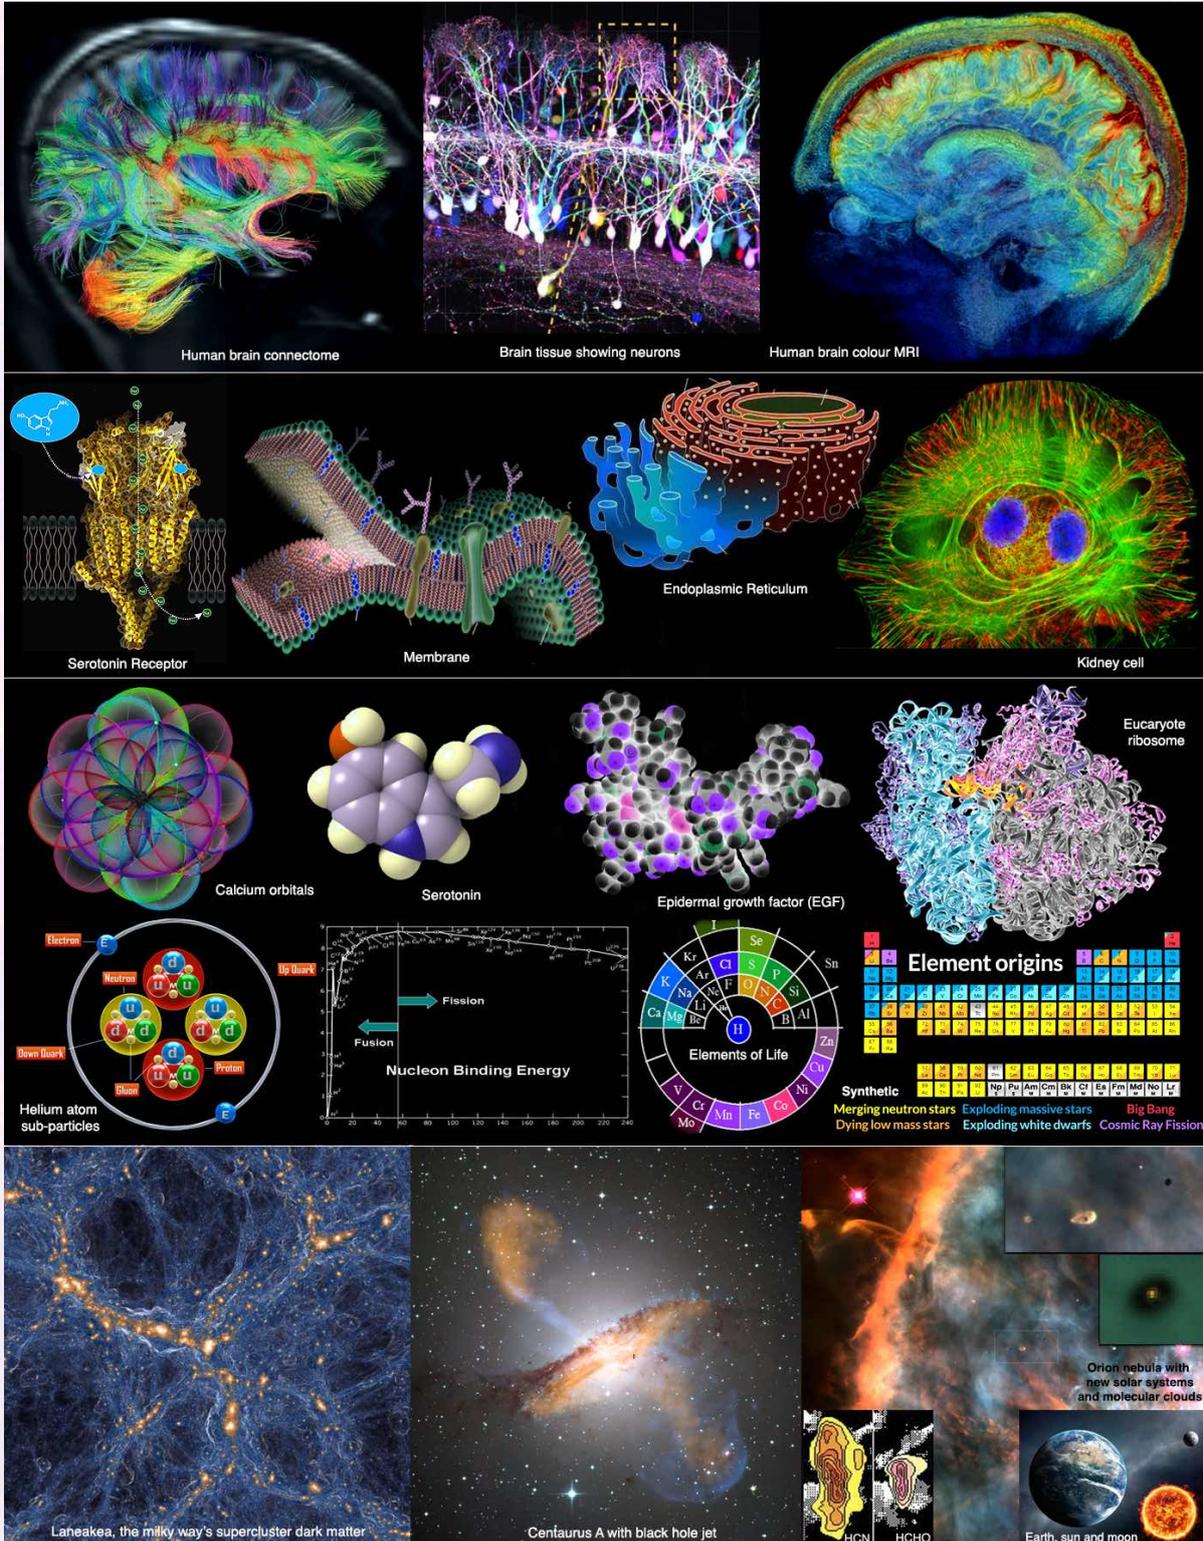

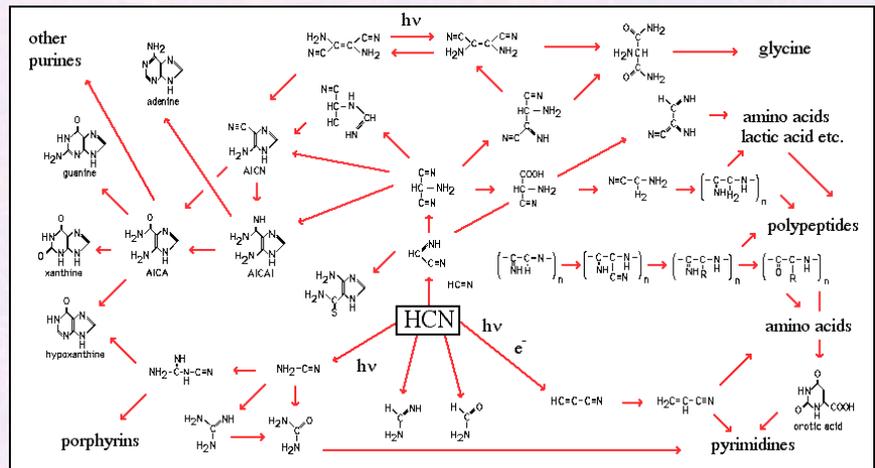

Fig 51 : Fractal biocosmology synopsis (See text below for discussion).

The physical universe and its laws hinge on investigations at two extremes, unified field theories of the fundamental forces at the quantum level and the evolution of the universe as a whole at the cosmological scale. At the quantum level, matter ends up being composed of multi-layered quantum structures, in which the strongest forces form interactive bonds first, and the rest follow in sequence of relative strength. The most complex of these quantum structures are atoms and molecules on the planetary surface, where all the forces come into structural interaction.

On the cosmic scale, following primal symmetry breaking, the universe forms a fractal structure of clusters of galaxies shaped by dark matter gravitational mass, called the cosmic web, illustrated above for the local Laneakea supercluster. Galaxies form, containing billions of stars, generally with massive black holes at their cores, as illustrated by Centaurus A above. Supernovae and colliding neutron stars end up generating the 100 or so atomic nuclei, seeding later smaller long-lived stars with the mineral elements. Among these galaxies are nebulae, consisting of gas clouds, in which star and planetary formation are taking place, such as the Orion Nebula above. These also contain gas clouds containing molecular precursors of life, from HCN and HCHO above to amino acids, seeding the biogenesis of evolutionary life. Radio-telescope data as early as 1974 (Buhl) demonstrated clouds of multiple-bonded $\text{HC}\equiv\text{N}$ and $\text{H}_2\text{C}=\text{O}$ spanning the region in the Orion nebula where several new stars are forming, fig 51. More recently, surveys from Hershel have produced high resolution maps of the distributions of HCN, and ionised H_2CO and NH_3 in both the Perseus and Serpens molecular clouds (Storm et al. 2014). These molecules form a core of primitive prebiotic syntheses in the laboratory, because multiple $-\text{C}\equiv\text{C}-$, $-\text{C}\equiv\text{N}$ and $>\text{C}=\text{O}$ bonds are some of the strongest covalent couplings in the universe, but are unstable to their higher energy π orbitals opening to make heterocyclic molecules, resulting in key prebiotic polymerisations. The nucleotide base adenine for example is $(\text{HCN})_5$ and is produced this way on industrial scales.

Fig 52: Polymeric pathways from HCN lead to both amino acids and nucleotide bases such as adenine (top left).

The four core forces of nature in the standard model plus conventional gravity, are symmetry-broken. The colour force, couples in triplets while the weak-electromagnetic couples in pairs of opposite charge. Their charge interactions display inverse quadratic non-linearities that make atomic and molecular matter have similar characteristics to Julia and Mandelbrot set fractals in terms of their quantum dynamics.

Gravity and electromagnetism both display inverse quadratic non-linearities, leading to chaotic dynamic regimes, both on solar system scales and in molecular interaction. Biological tissue is the ultimate expression of this quantum fractality in the universe as shown in fig 51. The abiogenesis of replicative life is a fractal molecular phase transition from a more diverse chaotic far-from-equilibrium milieu to the more ordered system of biomolecules in living systems, such as nucleic acids and polypeptides, which have evolved through subsequent functional refinement, a classic example of a transition toward the edge of chaos in living evolution from a more chaotic dissipative regime.

As shown in fig 51, the colour force gluons bind quarks in triplets of three colours and two base weak force flavours, forming protons and neutrons. These in turn become bound together by the strong nuclear force, a secondary effect of the colour force like the van der Waal's force in chemistry. Electromagnetism and the weak force have broken symmetry with one another. The equivalent of the electromagnetic photon, the X^\pm , and Z particles are both charged and inherit a large mass from coupling to the Higgs particle, discovered by the LHC. This means the weak force is very short range and operates primarily in the nucleus, exchanging the identities of neutrons and protons to minimise the energy in atomic nuclei and mediate the electromagnetic repulsion between positively charged protons. This in turn generates the diverse table of the atomic nuclei, the chemical elements and interactive molecular structures. A planetary surface, with a free energy source of incident solar radiation, held together by gravitation, sets the context for the negentropic quantum structural explosion we call replicative life. A hint of how symmetry breaking can interactively give rise to life as an entropy-defying unstable system can be seen from the simple [tippee top](#).

Life is present so far as we know only on planetary surfaces at much lower energies than the nuclear reactions of stars, where there is an incoming source of free energy in solar radiation, complemented by chemical gradients in the chaotic planetary environment, so it would appear that life can have little consequential affect on the evolution and fate of the universe as a whole. Traditional cosmology thus treats life as a phenomenon superfluous to the universe at large because the energies and forces of, not just of the big bang, or giant black holes at galactic centres, but even a small star like the Sun, are on a scale which would fry life to a crisp. However this picture, based on relative energy strengths, fails to appreciate the full scope of the interactive process set off by the cosmological symmetry-breaking of the forces of nature.

The chemical elements form a complex sequence of quantum structures, with orbital electrons captured by the positive charge of the nucleus, having non-linear energetics driven by the inverse quadratic electromagnetic force. The table of the elements is periodic in terms of the chain of s , p , d and f orbitals of successively higher spin and energy, according to linear Schrödinger equations and their ensuing σ , π molecular orbitals through electron sharing, but it is non-linear in terms of charge effects between negatively charged electrons and the positively charged nucleus. This means that the periodic table is not just periodic but a non-linear spiral of properties in which, for example O and S, N and P, and C and Si, each have quite distinct properties, although having the same outer orbital occupancy.

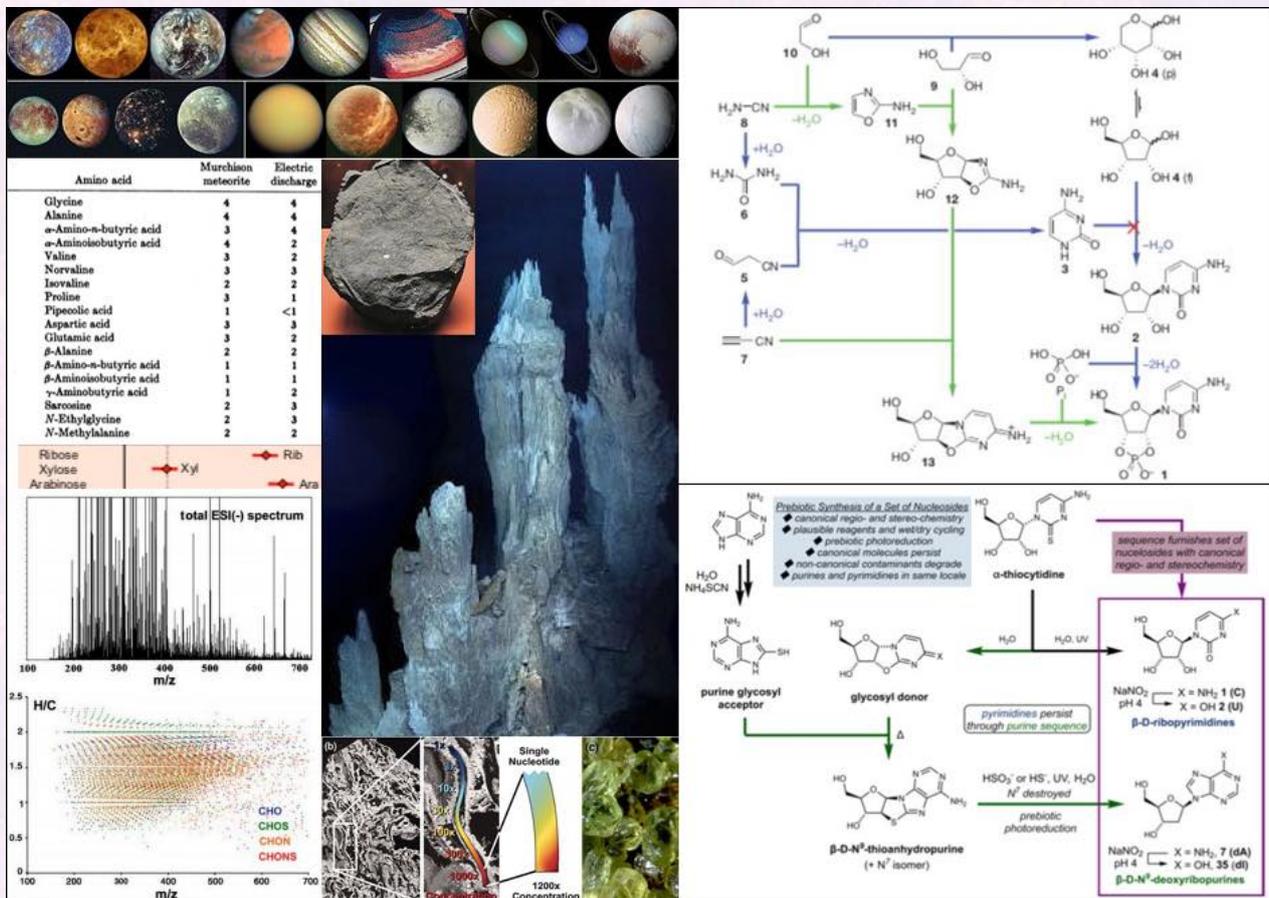

Fig 53: (King 2020a) Components of the link from organics in the universe to the origin of life on Earth. Top left: Solar system planets and moons of Jupiter and Saturn show divergent molecular compositions and chaotic surface phenomena, forming an open set of primordial conditions. Left: Murchison carbonaceous chondrite (inset), major amino acids and sugar components, and the sheer diversity of organic products. Centre left: Lost city vents formed by a chemical garden reaction between basic olivine (lower) and acidic sea water with dissolved CO_2 . Resulting H_2 and CO can drive the formation of organics including C1-4 hydrocarbons. These can be concentrated to biological levels (lower). Upper right: One pot synthesis of pyrimidine nucleotides (green), compared with the unsuccessful conceptual synthesis from ribose and pyrimidine subunits (blue) (Powner et al. 2009). Lower right: One pot synthesis of pyrimidine ribonucleotides and purine deoxyribonucleotides (Xu et al. 2020). Both weak force interactions and shoreline magnetism due to magnetite have been cited experimentally as ongoing sources of chiral catalysis (Ozturk et al. 2023). Papastavrou, Horning & Joyce (2024) have achieved RNA-catalyzed evolution of catalytic RNA.

The bioelements thus form a san-graal, or more correctly sang réal, "royal blood" relationship with the chemical elements as a whole as a core re-entrant interactive manifestation of cosmic symmetry-breaking, in which the strongest covalent elements – first row CNO – coupled with H form the core. The circular table of elements of life in fig

51 shows that these form a symmetry-broken quantum interference arrangement, centred on optimally covalent H-CNO as backbone-building elements complemented by ionic pairs K^+/Na^+ , Ca^{++}/Mg^{++} and Cl^- ; second row P, S adding additional pathways through polyphosphates and $-S-S-$ bonds, then extended by transition elements such as Zn, Cu, Co, Fe, Mn through to Mo as electronic catalysts. This gives a central cosmological status to life as the final interactive product of cosmic symmetry-breaking of the colour, weak and electromagnetic forces in the standard model of physics.

The orbital electrons are able to enter into a graduated series of chemical bonding structures, from strong covalent and ionic bonds, to weaker so-called hydrogen bonds and van der Waal's forces. Due to the non-linear energetics of cooperative weak bonding, interactively in a negentropic environment, these become able to generate fractal quantum structures extending up to the macroscopic scale of organisms, as illustrated by serotonin, the protein EGF and the ribosome complex fig 53, 54 – the factory to make proteins instructed by DNA, composed of RNAs and a number of ancillary proteins. On a larger fractal scale again, these form sub-cellular organelles, such as the membrane, as shown above and the endoplasmic reticulum. We then reach the scale of the single cell, illustrated in fig 54 for a kidney cell of a green monkey. Finally, we reach tissues in multi-celled organisms such as the olfactory bulb of the mouse above (Sakaguchi et al. 2018), then organs, illustrated above by the conscious human brain, the whole organism and the planetary biosphere.

Along with 15 amino-acids, all the nucleotide bases A, U, G, and C have been detected in carbonaceous chondrites, such as the Murchison and Tagish Lake meteorites (Glavin et al. 2012), carbonaceous chondrites containing primitive material from the Solar System's origin chemically altered by water during time on asteroidal bodies, before falling to Earth (Callahan et al. 2011, Oba et al. 2022). These also contain amphophilic membrane forming products. Alanine has been found to have a chiral excess of the L-enantiomer and L-excesses were also found in isovaline, suggesting an extraterrestrial source for molecular asymmetry in the Solar System. Ribose has been found in carbonaceous chondrites. The ribose in the Murchison has C13 levels 43% higher than terrestrial, confirming an extraterrestrial origin (Furukawa et al. 2020). Measured purine and pyrimidine compounds, including guanine, cytosine, adenine, thymine and uracil and others such as xanthine are indigenous components of the Murchison meteorite. The Murchison also contains phyllosilicates and olivine. Silicon carbide crystals in it date from as far back as 7500 billion years ago, nearly twice the age of the sun and solar system (Heck et al. 2020). Comets have likewise been shown to have primordial solar system organics, explaining how life appeared rapidly on the early earth after a period of heavy cometary and meteorite bombardment. The amino acids found have also been synthesised in laboratory experiments by the action of electric discharge on a mixture of methane, nitrogen, and water with traces of ammonia (Kvenvolden et al. 1972). A complex mixture of alkanes was isolated as well, similar to the Miller-Urey experiment.

A vast array of prebiotic molecules have been detected by mass spectrometry in the Murchison chondrite, of higher diversity than the present biosphere (Schmitt-Kopplin et al. 2009):

Here we demonstrate that a nontargeted ultra-high-resolution molecular analysis of the solvent-accessible organic fraction of Murchison extracted under mild conditions allows one to extend its indigenous chemical diversity to tens of thousands of different molecular compositions and likely millions of diverse structures. This molecular complexity, which provides hints on heteroatoms chronological assembly, suggests that the extraterrestrial chemodiversity is high compared to terrestrial relevant biological- and biogeochemical-driven chemical space.

This amounts to a clear manifestation of molecular pan-fecundity, a chaotic diversity of oligomeric fractal molecules with close to the ergodic maximum variety possible. These form an optimally fecund mix for subsequent edge-of-chaos dynamics on the planetary surface, balancing solar energy input against radiative degradation. This creates a far from equilibrium dynamic tending to minimum entropy production (Prigogine 1984, Klein & Meijer 1954), in which each type of molecule has a potentially catalytic influence through its orbital attractions, at the same time participating in creation annihilation events when bonds are formed and broken. But this isn't any kind of genetic panspermia, it is pan-fecundity of chaotic molecular diversity characteristic of the CNO-H + S component of the light elements on a rocky 'goldilocks planet' transitioning down to the temperature range of liquid H_2O . The process approaches chaotic fecundity because this optimally covalent molecular sector of the table of the elements, starts out with diversity and has no strong dynamic attractor to form predominant species, given the founding diversity and the opposing influences of anabolism and catabolism, so we end up with a quantum energy landscape with few strong attractors and ergodic diversity. Biogenesis then becomes a transition from deep molecular chaos towards the edge of chaos in which auto-catalytic populations emerge, and as we come closer to the edge, universal computation as in cellular automata ensues, eventually arriving at nucleotide replication and translation as a transition, leading to the reduced set of molecular varieties we find in metabolic biochemistry, RNA, DNA, proteins and lipids. This process is akin to an

ergodic version of adiabatic quantum computation, and the autocatalytic features constitute a selective process, affecting future survival of the species involved, whose catalytic potential is its “genetic” signature, forming a primitive evolutionary process in the collective auto-catalytic system as a prebiotic progenote.

Carl Woese (1998) coined this term for the kind of pseudo-organism that hypothetically existed prior to the universal common ancestor of all life LUCA. He described a process of genetic annealing, similar to neural net annealing on a potential energy landscape, at the point RNA replication and protein translation had both become established:

First consider the analogy: a physical annealing system starts at a high enough temperature that structures cannot form and then proceeds to slowly cool. In this quasi-stable condition, various combinations of the system’s elements form, dissociate, and reform in new ways, with only the most stable and structured of these combinations initially persisting, i.e., ‘crystallizing.’ As the temperature continues to drop, less stable structures begin to form, to crystallize, and many of the preexisting ones add new features, becoming more elaborate. In the evolutionary counterpart of physical annealing, the elements of the system are primitive cells, mobile genetic elements, and so on, and physical temperature becomes ‘evolutionary temperature,’ the evolutionary tempo. The evolutionary analog of ‘crystallization’ is emergence of new structures, new cellular subsystems that are refractory to major evolutionary change.

These considerations apply equally to the prebiotic transition before genetic replication and translation, when the catalysts were even weaker than early genetic systems only able to translate small proteins inaccurately and replicating erratically at lower fidelity. Therefore the entire autocatalytic population is required to maintain survival and evolution.

Lost city vents are formed by a chemical garden reaction between basic olivine and acidic sea water with dissolved CO₂. Olivine is cosmologically abundant on asteroids, Earth and the Moon and was far more abundant on the early Earth. Resulting H₂ and CO can drive the formation of organics including C1-4 hydrocarbons. Lost-city vents have been found to form carbonate columns with pores which have been demonstrated to be able to concentrate organics and in particular nucleotide molecules by a factor of over 1000 (Baaske et al. 2007), bringing them up to molar concentrations where a reactive metabolism and informational replication could be sustained. This provides a prospective nursery environment for life to emerge as a far from equilibrium complex dissipative systems becoming a cooperative progenote of replicating nucleotide and polypeptide molecules, with cell membranes and the genetic code arising later as an evolutionary product (fig 59).

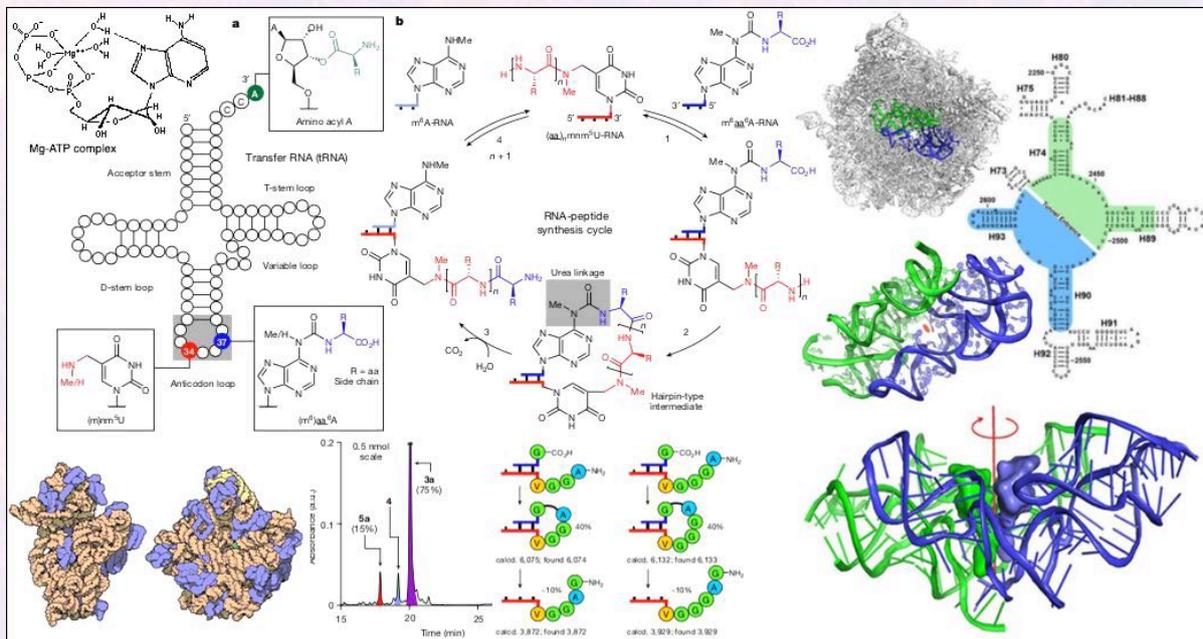

Fig 54: The ribosome (lower left) involving both two large rRNAs, (pink) with chaperone proteins (purple) the left one holding the mRNA and the right one building the nascent protein, along with small t-RNAs (upper left) specific for each amino acid which have to be coupled to their amino-acids by protein synthetases (Carter & Wills 2018). (Centre) A primitive precursor (Müller et al. 2022) to the dependence of RNA-based protein on the ribosome. Modified bases, still found on transfer RNAs (top centre) have been found to be able to induce formation of oligomeric chains of peptides (lower centre) by a cyclic process involving base pair binding between small RNAs carrying these modified bases (top right), confirmed by the chromatography rests (lower centre). (Right) Protoribosome, consisting of RNA molecules comprising only of some 120 nucleotides, about 60 for each of its two semi-symmetrical components, which accounts for less than 5 percent of the modern ribosome’s dimensions: some 4,500 nucleotides in bacteria and nearly 6,000 in humans. This forms a pocket able to join amino acids together. “Peptide bond formation is the most vital activity in any cell, and we’ve shown that it can take place within a protoribosome,” (Bose et al. 2022).

The “hard problem” of the critical step to replication has all but been solved in laboratory one pot reactions, fig 53, both capable of generating nucleotides from primitive precursors (Powner et al. 2009, Patel et al. 2015, Stairs et al. 2017) and a pyrimidine ribonucleotide and purine deoxy-ribonucleotide alphabet in the same pot (Xu et al. 2020). The key to understanding this is that all living systems are thermodynamically unstable dissipative systems depending on external sources of energy to maintain their polymeric stability, or the processes would immediately run to equilibrium in a terminal polymer. This is exemplified by the ATP-MG complex in fig 54, which is a single adenine nucleotide monomer with triple phosphates forming the principal energy currency of all metabolism demonstrating the exothermic nature of the polyphosphate bond that is also the linking bond in oligonucleotides.

This means that there is no stable polymerisation route to the first oligonucleotides, so that laboratory simulations for example of spontaneous RNA polymerisation cannot be performed without the complex substrate of prebiotic molecules that enabled this process, which necessarily take long lifetimes to explore the “topologically open” set of initial conditions that make this possible, although on evolutionary time scales they were short, as there is now evidence for life 3.45 bya ago, only around 500 mya after the oceans condensed (Schopf et al. 2002, 2018, Dodd et al. 2017). In every case where the route has proved difficult, from synthesising polynucleotides (fig 53) to RNA driven protein synthesis (fig 54), alternative pathways are subsequently discovered, that demonstrate the preconceived difficulties are due to failing to think outside the box, for example by assuming the sugars and bases have to be formed and then joined as whole units as fig 55 shows is fallacious.

Müller et al. (2022) fig 54, provide a third counter-intuitive ground-breaking discovery, showing that the modified RNA bases still present in transfer RNAs, when two RNAs hydrogen bond together can promote the polymerisation of amino-acids, providing a precursor route to the translation apparatus that later emerged in the ribosome. These modified bases, attached to short RNAs like tRNAs can co-synthesise peptide chains, forming diverse hybrid RNA-peptides with all kinds of catalytic functions no one had thought of. Here we have a demonstration of a completely new insight which has already been experimentally confirmed in the liquid chromatography assays in the figure and is thus feasible with the modified bases still existing in tRNAs, which is surprising in itself. Originally there would have been more. Confining RNAs to be pristine and proteins to be pristine is a misconception that has arisen because genetically coded translation later refined it to be like that. The underlying process is highly fecund as we should have expected, because amino acids are cosmologically abundant more so than nucleotide bases and have much more diverse catalytic diversity, so hybrid RNA-polypeptide molecules have more catalytic and complexity capacity to bootstrap abiogenesis. Bose et al. (2022), fig 54 have taken this a step further, discovering a semi-symmetrical proto-ribosome capable of forming peptides with only 5% of the ribosomal rRNA. These discoveries in one fell swoop demolish any irreducible complexity argument for the ribosome, transforming the paradigm of abiogenesis.

The climax of the cosmological interactive sequence emerging from the symmetry-breaking of the fundamental forces is conscious life. The brains of higher mammals and birds are the most complex coherent quantum structures we know of in the universe and thus, in terms of the cosmological interaction sequence, form their ultimate consummation. This structurally inverts the Copernican principle that humanity does not have a privileged view of the universe. Not only does it have a privileged view because we are conscious, both of ourselves and of the universe as a whole, but because we are its ultimate structural and dynamic expression, arising from the cosmic origin. A major concern is that of the Fermi paradox – the lack of astronomical evidence for extraterrestrial life. One critical hypothesis is not that intelligent life is unlikely, but that its probability for self-destruction destabilises the evolutionary paradigm through cultural misadventure, as we are seeing with human-induced climate and biodiversity crisis – the Medea hypothesis (Ward 2009).

Darwinian Cosmological Panpsychism

Darwinian panpsychic cosmology provides a description in which the subjective aspect is an integral complement to the objective physical universe, encapsulated in a series of evolutionary forms in: (a) individual quanta, (b) Gaia processes: Critically unstable multi-quantum dynamical systems, (c) living cells, (d) full consciousness in sentient form in eucaryotes (e) in organismic form in multi-celled organisms (f) in the evolving biosphere and (g) collectively in the universe. This is basically an evolutionary classification with edge-of-chaos phenomena and quanta linked by the butterfly effect. It replicates the results of standard quantum mechanics and of molecular biology, except in so far as idiosyncratic outcomes of quantum uncertainty, associated with collapse of the wave function are concerned, where the subjective aspect has functionality without disrupting physical causality.

it's perfectly reasonable to say that “the weather has a mind of its own”; it just happens to be a mind whose details and “purposes” aren't aligned with our existing human experience (Stephen Wolfram 2021).

Fig 55: Darwinian panpsychic cosmology synopsis

The cosmology thus replaces irreducible randomness of the Copenhagen interpretation of quantum mechanics with pan-psychic collapse generated through space-time quantum entanglement as input expressed in individual quantum events as output. Because irreducible randomness leaves the individual quantum free to manifest at any location in its equi-probable space normalised by the wave function, as consistent with the pilot wave interpretation's replication of standard quantum mechanics, no other inconsistencies arise. Because quanta may be also able to act under certain circumstances as interactive panpsychic "observers", the universe is able to collapse its own ramifying wave functions with human observer collapse just being a special case acting on unstable brain states, the multiverse (Deutsch 1997) becomes a real universe, arising from a phase transition between entanglement and collapse, with an ongoing line of history, as we perceive it.

This picture is one in which new probability branches are being created in the wave function by superposition in a similar manner to fractal cosmic inflation (Linde 1986, Hawking & Hertog 2018) while others are being collapsed by conscious measurement, resulting in dynamic evolution of the cosmic wave function. Special relativity, the most

classical part of quantum reality, is implicitly retrocausal as well as causal, as in quantum transactions, so quantum reality is implicitly anticipatory, involving transactional collapse across relativistic space-time in which a network of potential transactions become one or a set of real emitter-absorber interactions.

Fig 56: Fractal Cosmic Inflation leaves behind symmetry-broken universes.

These systems all inherit the capacity to avoid approach to classical macroscopic, limit as they are processes which are not IID systems generated by independent and identically distributed measurements (Gallego & Dakić (2021). Similarly, in the approach of stochastic electrodynamics (SED) (de la Peña et al. 2020), in which the stochastic aspect corresponds to the effects of the collapse process towards the classical limit ²⁸, consciousness has been proposed to be is represented by the zero point field (ZPF) (Keppler 2018).

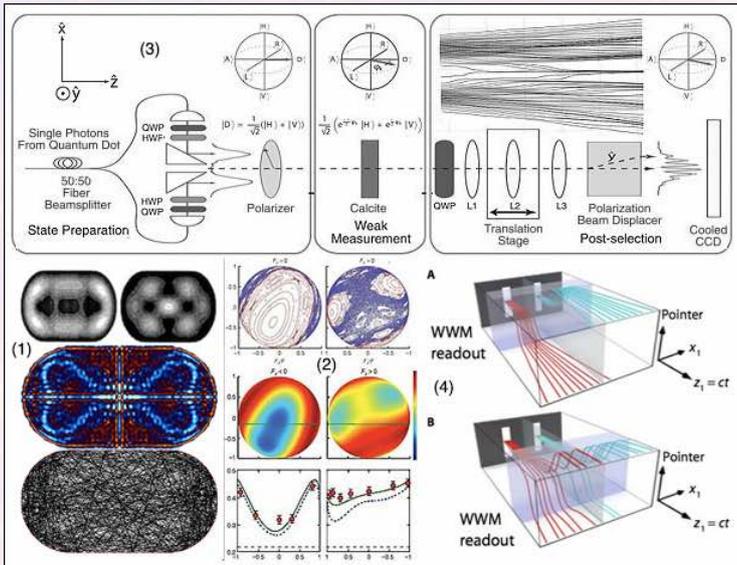

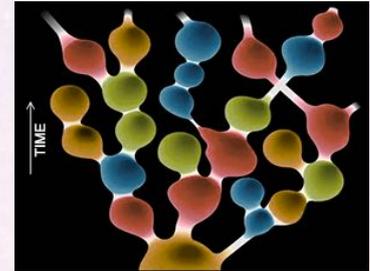

Fig 57:(1) The quantum stadium illustrates suppression of chaos in closed quantum systems. Top: Experimental realisation of scarring of the wave function around wave eigenfunctions, biasing the probabilities around unstable classical repelling orbits. Mid: Cellular automata simulation (King 2013). Bottom: Classical chaotic ergodic trajectory. (2) While the classical kicked top (above) shows similar regions of chaos to (1) in the Poincare map sections (top), the quantum kicked top (middle and bottom) shows chaos inducing entanglement with nuclear spin (Chaudhury et al. 2012). Entanglement between the electron and nuclear spins is quantified by the linear entropy, of the electron reduced density operator. (3) Weak quantum measurement demonstrating Bohmian trajectories (Kocsis et al. 2011). (4) Experiment confirming the existence of surreal Bohmian trajectories (Mahler et al. 2016). Conceptual diagram of the result of reading out the which way measurement (WWM) in a double-slit apparatus in the near field (A) and in the midfield (B). Color indicates the slit of origin of a Bohmian

trajectory, and vertical position indicates the result of the WWM. This surreal behaviour is the flip side of the demonstrated nonlocality. This nonlocality is due to the entanglement of the two photons, which, in Bohmian mechanics, makes their evolution inseparable even when the photons themselves are separated. Because entanglement is necessary for the delayed measurement scenario, this nonlocal behaviour is to be expected and is the reason for the surreal behaviour.

The Darwinian panpsychic description invokes seven broad evolutionary classes: (1) individual quanta (2) edge of chaos physical phenomena (3) excitable cells (4) eucaryote cells with informationally sentient membranes (5) organisms (6) evolving biospheres and (7) the universe as a whole. In this description, processes (1) – (3) consist of primitive subjectivity, while there is a discrete transition to sentient consciousness in (4) with the sequestering of respiration in the mitochondria with the eucaryote endosymbiosis, freeing the cell membrane for excitable sensitivity and social informational signalling via the molecules such as serotonin which evolved to become the principal neurotransmitters in the brain. This in philosophical terms, primitive subjectivity which philosophers call phenomenal consciousness is universally panpsychic and but the transitive structural details of subjective consciousness is emergent in a discrete transition with the eucaryotes, culminating in organismic consciousness through the constraints of neurodynamics. As noted, panpsychic quanta possess both consciousness through the space-time interactivity of the wave function and free will as a result if individual uncertainty, which Conway & Kochen (2009) show implies conscious free will.

Wong et al. (2023) also suggest that evolutionary principles may apply to natural phenomena extending beyond living systems by functional selection: “A star’s elemental abundances change over its lifetime; a hurricane incorporates many different parcels of air over its lifetime; organisms constantly exchange matter with their environment. We contend that Darwinian theory is just a very special, very important case within a far larger natural phenomenon. The notion that selection for function drives evolution applies equally to stars, atoms, minerals, and many other conceptually equivalent situations where many configurations are subjected to selective pressure (Robert Hazen).

²⁸ The approach of SED is guided by the hypothesis of the existence of the (random) zero-point radiation field, ZPF. This rather more elaborate approach goes through a statistical evolution equation in phase space, to arrive at a description in x-space, in which the dissipative and diffusive terms are seen to bring about a definitive departure from the classical Hamiltonian dynamics.

The eucaryote endo-symbiosis – a discrete topological transition of re-entry of the two founding life forms – archaea and bacteria – is the most outstanding evolutionary transition since the origin of life. It has resulted in edge-of-chaos excitability in the cell membrane, which becomes an arbitrarily sensitive sense organ due to the butterfly effect and also reaches to the quantum level invoking quantum uncertainty at unstable tipping points, thus freeing the dynamic to be causally open in a way which allows subjective conscious volition to intervene in the behavioural outcome. This is where attentive consciousness as we know it began and its principles have continued to be used by multi-celled organisms ever since in the diversity of conscious brains spanning the animal tree of life.

For this to have happened, not only the excitable brain, but its subjective conscious volition has to have retained an evolutionary advantage to the organisms possessing it in terms of anticipating immediate, or intermediate, threats to survival and opportunities to flourish. This suggests a form of anticipation which combines previous experience encoded by the brain with a form of conscious anticipation, which may utilise retrodictive aspects of quantum uncertainty.

Let's look at this evolutionary question more closely. The fact that the founding eucaryote membrane after endo-symbiosis became a chaotically sensitive complex dynamic doesn't mean it is just a physical dynamical system, or conscious volition never would have emerged and been elaborated in multicellular brains leading to our own conscious experience and volition. This process was a discrete topological transition freeing up the cell membrane for arbitrarily sensitive sentience and sensitive social communication via founding neurotransmitter molecules.

We are dealing with a choice between conscious attentive volition and automatic brain processing. These have to have physical differences in the organisms, so this is not the same as David Chalmers' zombies, which are conceived to be physically identical but are not conscious. It's not just a philosophical question, but an evolutionary one. If we define a "zombie" as an organism without conscious volition that is otherwise comparably similar to a conscious organism, there are two evolutionary arguments:

- (1) We know the eucaryote endo-symbiosis was a major evolutionary transition almost as significant as the origin of life itself and that all the ancestral archaea that gave rise to the eucaryotes have been swept off the face of the Earth by the very success of the founding eucaryotes. In this transition, procaryote "zombie" organisms possessing primitive subjectivity, but not sentient consciousness, evolved into and were replaced by conscious eucaryotes. This is however a phase transition in which both conscious sentience and a hugely improved energy and informational metabolism resulted, so it's hard to attribute a definable portion of the evolutionary advantage to conscious volition.
- (2) We can see in the evolution from single-celled eucaryotes to complex animal brains that these same intelligent cells have used the same dynamical basis to generate diverse brains providing a highly adapted environmental perceptual and behavioural dynamic using these same principles in their neurons. These first emerged in the loosely networked nervous systems of cnidaria such as hydra and then to mollusc, arthropod and vertebrate nervous systems all using the same founding edge-of-chaos neuronal dynamics and all of which appear to be conscious, as their tendencies to REM-like dreaming sleep attest.

This brings us to the second type of evolutionary advantage displayed by the universality of consciousness in animals. The ability of conscious organisms to out-survive mutational "zombies" that reduce or eliminate the role of conscious volition. The way consciousness in amoeba-flagellates appears to work is by the membrane having edge-of-chaos excitability with a butterfly effect which is causally open because it is quantum uncertain due to the butterfly effect. Now there is nothing stopping mutations in the organism tweaking this dynamical system to reduce or eliminate the source of this causal openness, which after all has a cost in terms of uncertainty of outcomes and a cost dynamically operating in this way. These zombies could arise by a variety of mutational avenues but there is no evidence for them. *Giardia lamblia* and related organisms have effectively lost their mitochondria, although there are relics present, and so present an example of retrogressive evolution, although this may not directly alter cell membrane dynamics.

This argument applies to all of evolution since, so it can apply to an organism like a fruit fly which could alter its developmental process so its neurons retreated from edge-of-chaos and differentially evolved to have entirely computational brains. Still they don't exist so far as we can experimentally determine, except perhaps for the roundworm *Cenorhabditis elegans* which comes close to computational organisation developmentally. Therefore the evolutionary argument holds.

Turning back to primitive subjectivity, many natural phenomena, take the form of edge-of-chaos processes, such as wind, waterfalls, thunder and lightning storms, from turbulent mountain summits to the ocean, which from the point of view of symbiotic panpsychism are strong candidates for primitive coherent subjectivity, consistent with animistic views. However it is not a physicalist form of panpsychism, as advocated by Galen Strawson (2006). SEC's form of panpsychism involves only root subjectivity, with brain dynamics as a boundary condition moulding how this is shaped into subjective qualia we experience, so it does not require the detailed analysis of how qualia are composed subjectively that arise in pan-protopsycho theories. Primitive subjectivity is consistent with the complementary subjective-objective picture of quantum reality of Vimal (2008, 2009), and in a more elaborate way by Boyer (2015).

This has a view of physical complexity which differs from integrated information theory (IIT), (Tononi and Koch 2015) in that it stresses the features of having unstable but coherent subjectivity as an unstable anticipatory property rather than system complexity as in the Markov complexity parameter of IIT, which is just an abstract mathematical formulation. Unlike Goff's notion of raw cosmic consciousness, possessing only elementary properties of agency and future awareness, the universe, like the biosphere possess forms of consciousness through the collective and individual subjective awareness of its participant biota.

While closed quantum systems such as nuclear energetics and the quantum stadium display suppression of chaos by energy separation of the eigenfunctions and by scarring of the wave function, as shown (1) in fig 57, chaotic systems where there is possible coupling to other interactions, such as the quantum kicked top (2) display additional quantum entanglement in the chaotic regime, exemplified by entanglement between electronic and nuclear spins in (2). This shows quantum chaos induces deeper levels of entanglement.

In weak quantum measurement (3), a photon released from a laser-excited quantum dot can demonstrate Bohmian trajectories by making a weak measurement which slightly disturbs the wave function without inducing collapse by absorbing the particle, which can then be used over multiple trials to map out individual trajectories over different time delays by detecting the particle's absorption. A significant aspect of this approach is that it involves a form of retrodiction, or backward causality we have seen in the Wheeler delayed choice experiment fig 74. Bohm's pilot wave theory involves a particle with a definite position shaped by a quantum potential derived from the wave function that carries all the other features such as spin.

Englert et al. (1992) noted that, in certain circumstances, the pilot wave theory could cause overlap of these real trajectories in such a way as to cause some trajectories in a two-slit interference experiment to behave as if they had come through the opposite slit to the one the Bohm interpretation implied, invoking a conflict with standard quantum mechanics. This caused a debate in the physics community, with opponents decrying the pilot wave interpretation. This was opposed by Basil Hiley, an original co-researcher with David Bohm. Hiley et al. (2000) stated : *"We also argue that contrary to their negative view, these trajectories can provide a deeper insight into quantum processes ²⁹."*

"This suggests that it may still be possible to retain the notion of a 'particle' even in the quantum domain. ... Alternatively we could give a more general meaning to these curves. For example, we could imagine a deeper, more complex process, which is not localised, but extends over a region of space where the wave function is non-zero. The curve could then be interpreted as the centre of this activity as this process evolves in space". ... "In spite of these limited successes, the nature of this deeper process is still very illusive and arises essentially from the non-commutative structure of the quantum algebra."

Mahler et al. (2016) demonstrated the actual existence of such trajectories, which are equivalent to streamlines of the probability currents in standard QM (Tastevin & Laloë F 2018), noting that their existence did not imply a conflict between the theories, but indicated instead a new level of quantum entanglement between the particles: *"This nonlocality is due to the entanglement of the two photons, which, in Bohmian mechanics, makes their evolution inseparable even when the photons themselves are separated. Because entanglement is necessary for the delayed measurement scenario of ESSW, this nonlocal behavior is to be expected and is the reason for the surreal behavior they identify. Indeed, our observation of the change in polarization of a free space photon, as a function of the time of measurement of a distant photon (along one reconstructed trajectory), is an exceptionally compelling visualization of the nonlocality inherent in any realistic interpretation of quantum mechanics"*.

Taking Hiley et al. and Mahler et al. at face value, we again have a situation where Bohmian trajectories are found to be consistent with quantum mechanics, confirming their validity in this context, but that the situation invoked by the experiment demonstrates deepening entanglement in these interacting systems.

²⁹ *"It is interesting to note that the surrealist movement in art claimed that there was more to reality than mere outward manifestations. There was a deeper reality (literally surreal means super reality) that lay behind outward appearances. When the word surreal is used with its intended meaning, then surreal trajectories is the correct term to describe them! Unfortunately [Englert et al.] use the term in a pejorative sense"* (Hiley et al.)

The validity of the pilot wave theory in these situations, when no issues of conflict arise with the Feynman path integral formulation, means it is also legitimate to propose that the deeper entanglement is playing a role in determining the position of the particle in the wave as any position in the probability space normalised by the probability amplitude is equally legitimate under the concept of irreducible randomness. Thus symbiotic cosmology is effectively consistent with both pilot wave and standard interpretations but suggests trajectories are derived from deep entanglement. When a theoretical explanation of any such quantum experiment is made, the quantum equations used to describe the outcome presume the only entanglements are the ones defined by the experimental apparatus used, but the quanta in the universe at large are all carrying a host of subtle entanglements from their past and future interactions and those of the other quanta they have interacted with. The equations are thus a first order ideal that masks the deep entanglement in both the experimental situation and the world at large..

Thus while panpsychic cosmology appears to introduce an ephemeral subjective complement to the universe, the effect is to give us back the real historical universe we experience, rather than the shadow multiverse of superimposed wave functions, because the subjective aspect of quanta participate in wave function collapse. The universe is thus not stranded from manifesting historically in the absence of conscious animate observers, but these animate observers through their consciousness are nevertheless able to also collapse wave functions in contexts like Schrödinger's cat for example those that are involved in brain function. Indeed this makes von Neumann's comment that collapse can happen anywhere up to the point of prescient conscious observation. In fact the traditional cat paradox experiment might collapse at the cat who is/was also conscious. But there are also diverse human strategic situations where tipping points occur and small acts of idiosyncrasy can have world-changing consequences.

Critically, it restores our subjective conscious ability to apply volitional will to affect the physical world around us. As noted in the introduction, all sane people have an implicit existential awareness that we make subjectively conscious intentional decisions and apply our volitional will to produce change in the physical world. We act and feel that we are intentional agents subjectively applying our will in our decisions and our actions and can do so through our intuitions. In this sense I am defining agency as the ability of subjective conscious experience to affect the physical world through the application of consciously experienced volition, resulting in physical effects, in our behaviour and actions. As noted in the introduction, affirming the efficacy of conscious volitional will leads directly to panpsychism, because some matter (brains) can manifest subjective consciousness affecting the physical universe, but because the brain is normal matter, obeying the four core quantum forces, even though these may involve exotic quanta such as quasi-particle excitations, subjectivity is a property complementing the physics of the universe. In this sense agency is subjective conscious volition intentionally affecting physical reality, unlike the purely objective notions of Moreno & Mossio (2015), where weak and adaptive agency are just objective dynamical structures.

The brain, in which continuous wave excitations and complementary discrete phased pyramidal action potentials are forming, is a process at face value homologous to quantum observation of edge of chaos dynamics at unstable tipping points. The role of consciousness as a quantum observer of the brain's own attention dynamics, noted in Graziano's (2016) AST model, would enable a quasi-causal role for volitional will to avoid lethal misadventure, by filling in the uncertainty gaps in edge of chaos computation and thus validate our veridical impression of possessing autonomous will as real rather than the delusion materialists claim. Human decision-making has a similar idiosyncratic nature to single quantum events I shall call a **quantum instance**, just as evolution is a sequence of adventitious quantum transformations, every one of which is a single unrepeated quantum instance, none of which individually converge to the classical expectation of the probability amplitude. In this way there is a deep correspondence between human decision making, evolutionary mutation and the cosmological idiosyncrasy³⁰ of a single quantum instance, which is completely uncertain. Hence the free-will of the quantum is its instance and our volitional will is also an instance.

See: [Primal Foundations of Subjectivity](#) for a further explanation of this process.

9 Cosmological Symbiosis

We next explore how the [fractal](#) and [panpsychic](#) cosmological pictures fit into a deeper [symbiotic](#) picture, in which biological life, the universe and consciousness all enter into a symbiotic relationship extending the manifest [biological symbiosis](#) that is the basis of the endosymbiotic eucaryote cell, eucaryote sexuality, cell-virus symbiosis and the natural and sexual selection (Darwin 1859, 1889), that is universal in the biosphere.

³⁰ *idiosyncrasy* a mode of behaviour or way of thought peculiar to an individual *idiosunkrasia*, from *idios* 'own, private' + *sun* 'with' + *kraasis* 'mixture'.

Fig 58: The Huichol nierika or portal to “ultimate reality” and the “spirit world”: Cosmological symbiosis realised through psychic symbiosis.

Cosmological Symbiosis

Cosmological Complementarity

1. The **physical universe has a veridical**³¹ complement – **cosmological consciousness**, or the “mind at large”, the subjective manifestation of the cosmos. Individual human consciousness is an encapsulated instance of the whole.
2. The mind at large **shapes physical history** in the quantum multiverse, through **volitional will** collapsing the superimposed, quantum-entangled wave functions. Full scale cosmology image

Biogenesis

3. **Cosmological fecundity**: The physical universe is the most complex quantum fractal conceivable in space-time, due to cosmic symmetry-breaking of the four quantum forces – gravity, the weak and colour forces and electromagnetism.
4. Consequently emergent molecular action is a complex fractal quantum process, culminating the symmetry-broken interaction of the four quantum forces of nature.
5. At the same time, planetary conditions permeate the degrees of freedom for biogenesis, due to chaotic dynamics of gravitation and the other forces.
6. Consequently, due to ergodicity³², replicative life will take root in an open subset of cosmological conditions.

Evolution

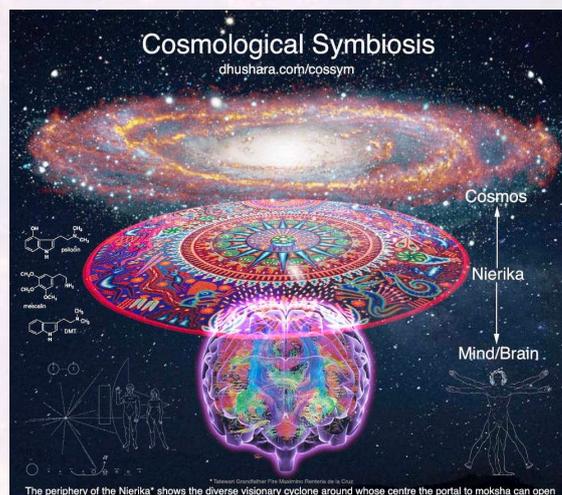

7. **Computational catastrophe**: With the advent of genetic evolution, molecular interaction becomes a complex massively-parallel quantum computer, accumulating adventitious information through mutation and natural selection.
8. **Cellular excitability**: Edge of chaos excitable cells gain a coherent encapsulated form of panpsychism, which is adaptive to survival and is thus selected for.
9. **Eucaryote symbiosis** between the two founding branches of life, archaea and bacteria, triggers a **complexity catastrophe**.
10. **Cellular consciousness**: Adaption to environmental modes of quantum perturbation of cell excitability in eucaryotes results in cellular sentience. This is the critical transition to existential consciousness. The transition to brains is a secondary extension.
11. **Signalling molecules**, such as serotonin, evolve to mediate modes of social interaction conducive to survival of the collective organism in single celled eucaryotes, also affecting epigenetics and, by selection over the result, genetics.

Organism

12. As organisms evolve to become multi-celled, cellular consciousness becomes **organismic consciousness** via neuronal coupling.
13. **Fractal culmination in the Biota**: Conscious organisms become the consummating fractal interactive expression of cosmological symmetry-breaking, running from quarks through nuclei, atoms and molecules, to molecular complexes such as the membrane and ribosome, to cell organelles, cells, tissues, organs such as the brain, societies of organisms and the symbiotic biosphere.
14. The brain’s organismic consciousness becomes **evolutionarily adapted** to aid the **survival of the organism** and the family.
15. In mammals, this involves **limbic emotions**, invoking a dynamic network for survival that we consciously identify with **the ego**.
16. At the same time, the brain, as a closely-coupled society of neuronal cells, interacting via the same signalling molecule types, remains **dependent on elementary amine-based neurotransmitters**, to modulate key survival strategies, because these arose from modalities directly ensuring the survival of the collective organism in single-celled species.
17. **Involution**: Again at the same time, given the variety of niches on an Earth-like planet, several species are likely to evolve to synthesise modified amino acid derivatives (e.g. psilocin, DMT, mescaline), capable of altering the dynamics of consciousness in such a way as to bring individual consciousness back into relationship with the mind at large using the same receptor pathways.

Biospheric, Psychic and Cosmological Symbiosis

18. All living species, including humans, survive through evolutionary niches in effective **biospheric symbiosis** with the whole.
19. Because *Homo sapiens*, the currently dominant species on Earth has evolved an **ego-based form of individual consciousness**, evidenced in our tribal emergence, our species is not adapted to, and thus **lacks the intrinsic ability to care for the planet** mindfully enough to avoid exploiting it to the extent that it becomes **critically compromised**, threatening human survival.
20. **Entheogenic species** bearing **psychedelic neurotransmitter analogues**, by tweaking a central brain survival mode at the receptor level, can precipitate **ego dissolution**, leading to **moksha** – reunion with the “mind at large”, thus evoking a psychic symbiosis with humanity complementary to our inter-dependence with food, medicinal, and biosphere-supporting species.
21. This psychic symbiosis enables humanity to find its role as the guardians of the living planet and the flowering of conscious existence in evolutionary and cosmic time scales, rather than becoming its tragic “*espèce fatale*”, thus resolving the existential and planetary crises, fulfilling the spiritual, eschatological and scientific quest for the meaning and purpose of intelligent life.
22. **Psychic symbiosis** is potentially as significant as the eucaryote symbiosis, because the future survival of the planet’s entire living diversity is at stake and it is thereby manifesting **cosmological symbiosis** of the physical universe and mind at large, thus providing a means to avoid a mass extinction of biodiversity invoking the self-destruct scenario of the Fermi paradox.

³¹ *veridical* – coinciding with reality (Oxford Languages). Mid 17th century: from Latin *veridicus* (from *verus* ‘true’ + *dicere* ‘say’) + *-al*.

³² *ergodic* – relating to, or denoting (e.g. chaotic) systems or processes with the property that, given sufficient time, they include or impinge on all points in a given space and can be represented statistically by a reasonably large selection of points.

Symbiosis and its Cosmological Significance

According to Thomas Hertog (2023), in a post-humous follow on from Stephen Hawking's "Brief History of Time (1988), the new perspective that he has achieved with Hawking reverses the hierarchy between laws and reality in physics and is "profoundly Darwinian" in spirit. "It leads to a new philosophy of physics that rejects the idea that the universe is a machine governed by unconditional laws with a prior existence, and replaces it with a view of the universe as a kind of self-organising entity in which all sorts of emergent patterns appear, the most general of which we call the laws of physics."

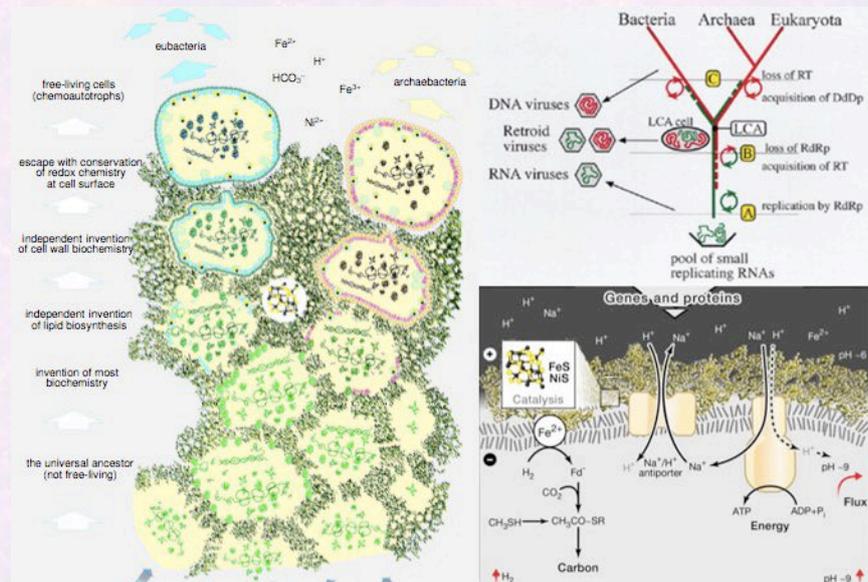

It is critically important in this discussion to understand how pivotal symbiosis is to the continuity of life in the universe. When we talk about survival of the fittest and the notion of the selfish gene seeking its own replication, these both occur in the context of natural selection, which is selection by symbiosis with the biosphere as a whole. Apart from a few extremophile archaea whose niches are predominantly geospheric, all evolutionary niches are biospheric, relative to the living diversity of all other species defining the niche, so natural selection is the key vector of biospheric symbiosis. Thus the capitalistic notion of survival of the fittest in the concrete jungle of human economic business as usual is a biospheric tragedy of the commons, (Hardin 1968) resulting only in planetary crisis, as a misaligned manifestation of human tribal origins. Species we see as predatory, or parasitic, also have symbiotic roles in ensuring the survival of their hosts and prey. For example, carnivore predation also avoids their herbivore prey populations going into boom and bust extinction by eating out all their vegetative food supplies.

All the interesting things in the universe happen at the edge of chaos (Teuscher 2022). Cosmological symmetry-breaking causes the structure of molecular matter to be potentially fractal so with bio-elements we get the fractal structure of tissues. The edge of chaos is an abstract principle we can find throughout nature and cosmology. It is manifest in complementary regimes of order and chaos in both continuous and discrete dynamics and in discrete cellular automata where edge of chaos system 110 is a universal computer (Chen et al. 2012, Cook 2004). It is a fundamental concept in key transitions in brain states in the Freeman model of neuronal dynamics and is a critical aspect of evolution's rise to climax diversity.

We have also noted that there is a beautiful Goldilocks scenario for the origin of life. Firstly the galactic nebulae are flush with the primordial molecules that readily polymerise to nucleic acid bases and amino acids. Secondly the acidic CO₂-filled ocean reacts with crustal alkaline olivine to form chemical gardens just like the one's I made as a kid. They were rife on the early Earth and still occur today in the Lost City vents. Experiments have shown they can also concentrate biomolecules 1200 times up to biological concentrations and feed them on the chemical reactions produced.

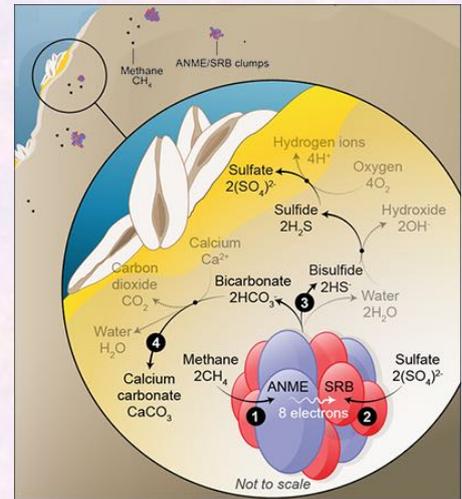

Fig 59: Left: Emergence of archaea and bacteria as complementary cellular life forms with differing membrane structures from the common progenote (Lane & Martin 2003). Top right: The divergence happened before the evolution of DNA polymerases (Leipe et al. 1999). Lower right" The electrochemiosmotic foundation of cellular life (Lane & Martin 2012).

The end result is the chemiosmotic origin of life where membrane electrochemistry set the whole process going. This gave rise to two fundamentally complementary life forms, archaea and bacteria as well as a lot of viruses emerging from a cooperative milieu called a progenote in which viruses and transposable genetic elements provided a sexual complementation to emerging cellular life forms. The archaea are geological organisms in salt pans, hot smokers, methane swamps, and volcanic hot pools. They don't cause diseases. Bacteria are fast metabolic organisms that decompose, photosynthesise and respire and can be pathogenic.

Archaea have different kinds of cell walls from bacteria, so it is likely that each emerged from the progenote and became cellular as they escaped gaining metabolic autonomy via the membrane energetics. The DNA polymerases of archaea and bacteria are also different, so it also looks as if they evolved and diverged before DNA-based life had stabilised, at a point where DNA and RNA were flipping cyclically using the reverse transcriptase that is still in retroviruses like HIV and in the endogenous retroviruses in our genomes and in telomerase!

Fig 59b: The anaerobic oxidation of methane would not be possible without a close coupling between anaerobic methanotrophs ANME and sulphate-reducing bacteria SRB. Methane is a high-energy but very stable molecule: it is not easy to crack it open to release electrons and power metabolism. Anaerobic methanotrophs can do the job, but they end up releasing an overabundance of electrons as a result, leading to a backlog that would normally cause their metabolism to grind to a halt. Sulphate-reducing bacteria use the surfeit of electrons to turn sulphate into sulphide and reap the energetic windfall that results. It is a classic symbiosis: the anaerobic methanotrophs enjoy a swift trash collection service, and the sulphate-reducing bacteria bask in an in-house power plant. In the progenote era many fundamental metabolic cycles may have evolved symbiotically in this way. But the co-evolution leads to mutual dependence, as genomes come to depend on the presence of molecules they cease to synthesise (Marlow & Braakman 2018).

Life thus started out with two complementary life forms, but then about 2 billion years ago an edge of chaos event happened, when a very slowly growing archaean, with long protruding filaments started to grow alongside alpha-proteo-bacteria like our gut bacteria *Escherichia coli*, using the relationship to live off their high value respiratory electron transport chain energy while also giving them value in return by exchanging metabolites. You can see close relatives of these two species top right in fig 60 below. There are still some archaea and bacteria that do this today, but basically what happened is that the symbiosis was so successful that it wiped all trace of itself off the face of the Earth in a rapid quantum leap of evolution to form the higher nucleated eucaryote cells that make amoeba-flagellates and complex organisms. Without this symbiotic quantum leap complex life could not exist!

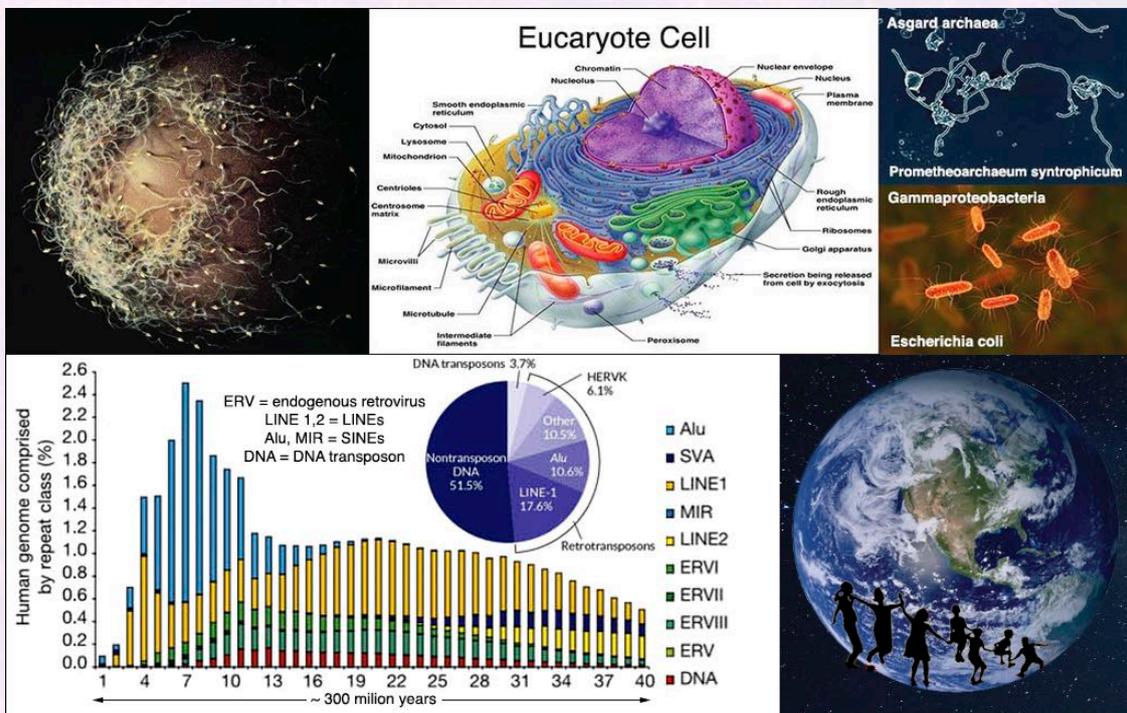

Fig 60: Symbiosis is ubiquitous and essential to human life. Top Left: Human fertilisation. Symmetry-broken sexuality is a form of intra-species symbiosis between the genetic sexes. Top right: The symbiosis between archaea and bacteria to form the eucaryotes, leading to all complex life. Lower left: Transposable elements occupy nearly half the human genome, have co-evolved with humans since the formation of multi-celled organisms and have inherited key symbiotic roles. See also [major evolutionary transitions](#) Lower Right: Homo sapiens can survive as a species only by symbiosis with the biosphere, within which our very existence interdepends. Human religious and commercial dominion over nature runs completely counter to biospheric survival over cosmological time scales and is frank evolutionary suicide.

Eucaryote endo-symbiosis

About half our genes, the metabolic ones, were derived from the bacterium and are now in the nucleus while the informational processing genes came from the archaean. Now the mitochondria have only a skeleton set of key genes constituting the maternally inherited mitochondrial DNA that showed us that the African Eve was a San woman.

Elucidating how this happened genetically from previous organisms didn't happen until a few years ago. In 2019 Lokiarchaea, the first of the Asgard archaeans to be discovered was finally successfully grown in culture. It had originally been identified as a unique archaeal organism from microbial mud, dredged near Loki's Castle, a sea-floor hydrothermal vent field off the coast of Greenland. In a 2015 study in metagenomics, Ettema and his colleagues sequenced genetic fragments from the microbial portion in the sediment and assembled them into fuller genomes of individual species. One genome stood out. It was clearly a member of the archaea. But dotted throughout this genome were eukaryotic-like genes, named Lokiarchaea, after Loki, the trickster of Norse mythology (Lambert 2019). However, unbeknown to the metagenomics researchers, Hiroyuki Imachi and colleagues (Imachi et al. 2019) had been working since 2007 to cultivate microbes from deep-sea sediments. They built a bioreactor that mimicked the conditions of a deep-sea methane vent. Over 5 years, they waited for the slow-growing microbes in the reactor to multiply and then took samples placed these, along with nutrients, in glass tubes, which sat for another year before showing any signs of life. Genetic analysis revealed a barely perceptible population of Lokiarchaea. The researchers patiently coaxed the Lokiarchaea -- which took 2-3 weeks to undergo cell division -- into higher abundance and purified the samples. Over 12 years, in a breakthrough work, the researchers produced a stable lab culture (*Prometheoarchaeum syntrophicum*)

containing only this new Lokiarchaeon and a different methane-producing archaeon in a symbiotic relationship. The researchers sequenced all the microbe's DNA, confirming that it does contain some genes that look like those found in eukaryotes. This has now enabled verification that the cultured genome contains the eucaryote-related genes from the metagenomics analyses and enables a much more detailed investigation of this critical group of organisms.

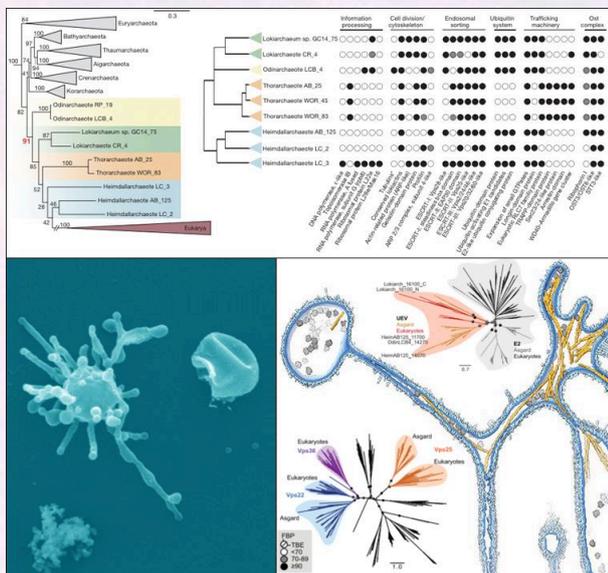

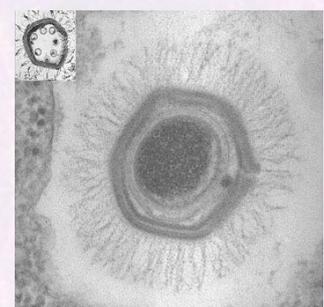

Fig 61: Top: Ettema's team (Zaremba-Niedzwiedzka et al. 2017, Eme et al. 2023) have found a superphyllum comprising archaea in diverse environments including marine sediments, aquifers and hot springs which have a phylogenetic relationship with eucaryotes and include genes for vesicle formation, membrane-trafficking components and cyto-skeletal functions including ESCRT and TRAPP domains. Bottom: *Candidatus Lokiarchaeum ossiferum* (Rodrigues-Oliveira et al. 2022). Insets: Evolutionary trees of ubitiquitin genes UEV, E2, Vps22 and Vps25 (Hatano et al. 2022).

By carefully decanting cell cultures Rodrigues-Oliveira et al. (2022) have isolated a new Asgard *Candidatus Lokiarchaeum ossiferum*, which has a significantly larger genome compared with the single previously cultivated Asgard strain (Imachi et al. 2019). Wu et al. (2022) isolated two other Asgard species—from rock collected from a hydrothermal vent in the Gulf of California to sequence their complete genomes. These harbored mobile pieces of DNA that contained bacterial genes involved in metabolism, suggesting these elements played a critical role in transferring genes among life's major branches. Hatano et al. (2022) have discovered four ubiquitin-ESCRT gene complexes eukaryotic cells use to bend, cut up, and stitch together their membranes to link internal compartments. On the other hand, Knopp et al. (2021) calculated that Asgard archaea contributed as little as 0.3% of the protein families believed to exist in the common ancestor of the eukaryotes, suggesting that the stresses on the host drove eucaryote complexification, such as the nucleus, Golgi apparatus, and the evolution of sex (Raval, Garg & Gould 2022).

Fig 62: *Mamavirus (mimiviridae)* with double membrane and capsid and parasitic phage.

Viral eucaryogenesis: There is also evidence from key genes involved in both viral and eucaryote replication and transcription, that both the cell nucleus and mitosis and sexual meiosis arose from a lysogenic DNA virus than can integrate quiescently with the host cell genome, with a double membrane envelope, that invaded the endo-symbiont, or its archaeal precursor, and rather than just altering its transcription to the virus's

advantage, went further and captured the archaean genetic organisation, to the extent that replication of the viral nucleus became coupled to replicating the entire archaean and viral genome, with transcription sequestered outside the nuclear envelope.

Telomerases appear to have viral origins (fig 63). Many classes of nucleocytoplasmic large DNA viruses (NCLDVs) such as mimiviruses have the apparatus to produce m7G capped mRNA, as in eucaryotes, and contain homologues of the eukaryotic cap binding protein eIF4E. (Bell 2001, 2006, 2009, 2020, Chaikerasak et al. 2017a, b, Claverie 2006, Trevors 2003, Takemura 2020, Villareal & Witzany 2009). Asgard viruses and TEs have recently been described, with genes in transition between archaean and eucaryote forms (Rambo et al. 2022, Wu et al. 2022). Indeed, viral eucaryogenesis could have been the founding event, leading to endosymbiosis.

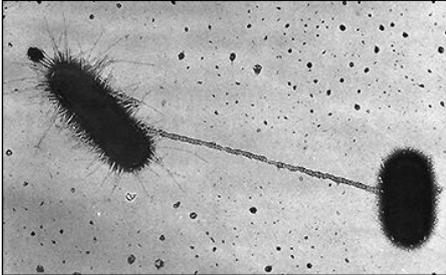

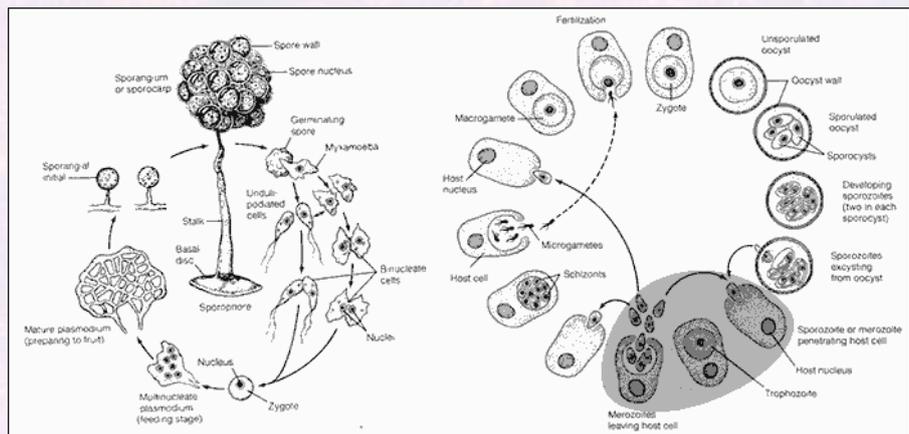

Fig 62a: Procaryote cell-virus symbiosis. TE-encoded sexual conjugation plasmid recombining genomes between two distinct species of bacteria.

Sexuality (King 2016) is a form of genetic symbiosis both between viruses and cells and between the two or more sexes of a species. Sexual recombination is essential to avoiding mutational degradation. Sexual exchange is universal in procaryotes (archaea and bacteria), through a symbiosis between the cellular and viral genomes, where plasmids and viruses also serve to exchange genetic material between hosts.

Concomitant with the establishment of the archaean-bacterial endosymbiosis, eucaryotes established both mitotic and sexual meiotic genetic replication, in which each parent contributes half their diploid genome to make haploid gametes, with indexed chromosomal crossing-over of gene alleles. Subsequently this became symmetry-broken to sperm-ovum dyadic sex, to avoid cytoplasmic genetic warfare between the maternal and paternal symbiotic mitochondria and chloroplasts, resulting in the two genetic sexes in each species (more in fungi), each becoming genetically interdependent with one another for survival and hence sexually-symbiotic, with the mitochondria being inherited down the maternal line. A founding reason why all complex life is sexual and why we thus have the dilemma of individual mortality, is that the diversity of sexual individuals in a species protects the species in the peacock's tail race against its sexual parasites. A key role of eucaryote sexuality is to enable this, where sexually inherited genomic differences act to prevent total extinction of a monoclonal parthenogenetic host species, so that with very few exceptions, at least cryptic (intermittent), sexuality is universal. But sperm-ovum sex is a prisoners' dilemma of highly asymmetric reproductive investments, leading to sexually antagonistic co-evolution, starkly displayed in humans in attempts by men to assert patriarchal dominion over female reproductive choice in an evolving culture of female gatherer reproductive cooperation, leading to male social repression and control of the female sex by veiling, female genital mutilation, chaperoning by male relatives, stoning for adultery, honour killings, lack of ability to work, or to have a full education and professional life.

Fig 62b: Sex becomes gender. The slime mold *myxomycota* has flagellated isogametes, while *apicomplexa* although a simple single celled protocist already has sperms and ova (Margulis and Schwartz 1982).

Cell-virus symbiosis is also rife in the human genome (King 1985, 1992, 2020c), where transposable elements (TEs) occupy 46% of the human genome, of which only around 2% is protein coding, making the TE content of our genome one of the highest among mammals, second only to the opossum genome with a reported content of 52%. LINE-1 elements which have co-evolved in the human germ line with a history running back to the Eukaryote origin, numbering 100,000-950,000 partially defective copies, around 100 of which remain fully active in humans, and their 300,000 dependent smaller fellow traveller Alu SINEs, together comprise 33% of the human genome. Long terminal repeat (LTR) retro-transposons 8% and DNA transposons 3%. Retroviruses related to HIV also exist in endogenous forms in the human germ-line, comprising up to 5 to 8%. Giving an evolutionary comparison, the slime mould *Dictyostellium* has both LTR- and retro-transposons

occupying 10% of a gene dense genome in which around 66% codes for proteins (King 1985, Malicki et al. 2017). The survival of such a high proportion of transposable elements in such a tightly packed genome is strong evidence for symbiosis. In terms of the selfish gene (Dawkins 1976), transposable elements notwithstanding, organism genomes are one huge genetic symbiosis, through organismic survival and selection.

Ivancevic et al. (2016) have traced the evolutionary tree of LINE-1 back to the founding eucaryotes as L1 elements occur in both plants and animal phyla spanning vertebrates, arthropods, and molluscs such as octopi where L1 transposition has specifically been associated with high-intelligence where transcription and translation measured for one of these elements resulted in specific signals in neurons belonging to areas associated with behavioural plasticity (Petrosino et al. 2022). L1, along with DNA transposons and LTR retroelements are ubiquitous across the arthropod kingdom (Petersen et al. 2019) and span the eucaryote tree. So cell-TE/virus symbiosis is foundational to eucaryotes.

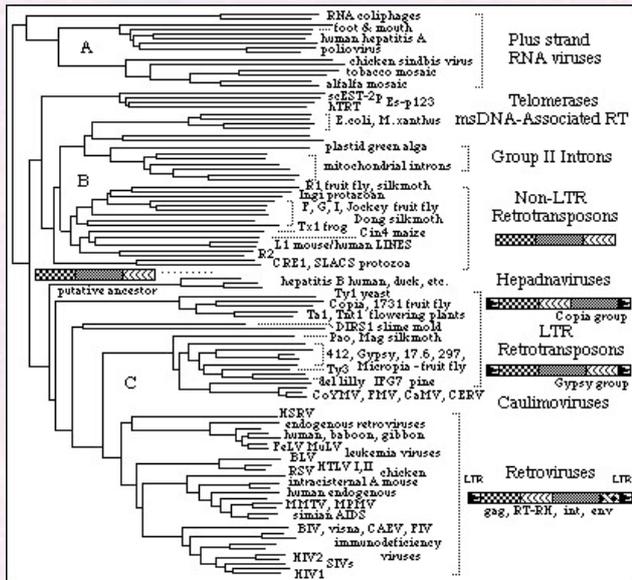

Fig 63: Eucaryote cell-virus symbiosis. Retrotransposons (Xiong & Eickbush 1990), which replicate by copy and paste transcription and reverse transcription of RNA to DNA and insertion into the genome, are present in all eukaryotic genomes, where they constitute the most abundant class of mobile DNA, in many cases, around 50% of the nuclear DNA, a situation that may have arisen in just a few Myr. They play a central role in the structure, evolution, and function of eukaryotic genomes. Retroviruses evolved during the early Palaeozoic Era, between 460 and 550 million years ago, providing the oldest inferred date estimate for any virus group (Hayward 2017). Although they are found only in vertebrates, the wider grouping C of metaviridae, which have evolved from LTR retrotransposons are ubiquitous across eucaryotes, populating diverse eukaryotic genomes, such as *oomycetes*, slime molds, fungi, plants and animals (Gorinsek et al. 2004).

Having integrated with our germ line, such elements both result in transpositions, which can cause mutations and genetic disease, but have also co-evolved to perform essential symbiotic tasks. Many of the historical transpositions have also caused adventitious mutations, giving the inserted elements key functions in coordinated gene expression. LINE-1 elements are key to forming the blastula, have key expression in neural progenitor cells and are essential in collapsing one of the two X-chromosomes which are poisonous to females except in their germ line. Endogenous retroviruses have provided membrane budding genes such as syncytin, which aid the formation of the syncytium, the super-cellular membrane that enables nutrient diffusion from the mother to the baby and immunity evasion, which avoids rejection of the embryo (Mi et al. 2000). Endogenous retroviral genes, such as suppressyn in humans, like in other mammals have been found to confer resistance against exogenous retroviral infection (Frank 2022). The recombination activating gene protein RAG1/RAG2, essential for the mutational variability of the vertebrate immune system, appears to have evolved from an ancient DNA transposon common to the metazoa (Agrawal et al 1998, Kapitinov & Jurga 2005).

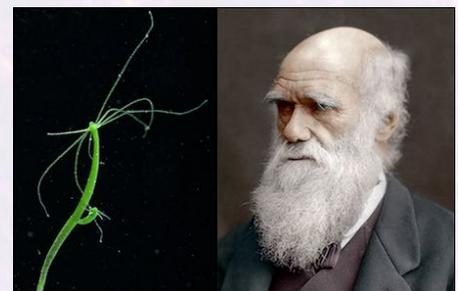

Organisms and Cellular Symbiosis.

One needs to understand at the outset, that an organism is a collective colony of cells living symbiotically together and that although each cell in an organism shares the same genetic heritage in its DNA, there is no overall imposed order, other than the cellular intercommunication that enables differentiation and embryonic development to occur.

Fig 63b: Cnidarian *hydra* is envisaged as a colony of cells. Here *H. viridissima* is both carnivorous and in symbiosis with *Chlorella* algae, as is common with coral polyps. By contrast, advanced metazoa such as *H. Sapiens* are regarded as developmentally regulated organisms, but both stem from autonomous processes of colonial cellular differentiation and embryonic interactive development which is also a crowning manifestation of cellular symbiosis.

Indeed Darwin commented:

“To see a puppy playing [one] cannot doubt that they have free-will” and if “all animals, then an oyster has and a polype.” (Darwin ex Smith 1978)

Lynn Margulis has been pivotal, both in establishing the correct view of eucaryote endosymbiosis, and in conveying the importance of symbiotic relationships in evolution generally, and finally in biospheric terms, in her cooperation with James Lovelock, in establishing the Gaia hypothesis, which is itself a form of symbiotic mutually stabilising relationship between the entire biosphere and the major planetary geochemical cycles.

Lynn Margulis opposed competition-oriented views of evolution, stressing the importance of symbiotic or cooperative relationships between species. She later formulated a theory that proposed symbiotic relationships between organisms of different phyla or kingdoms as the driving force of evolution, and explained genetic variation as occurring mainly through transfer of nuclear information between bacterial cells or viruses and eukaryotic cells. Her organelle genesis ideas are now widely accepted, but the proposal that symbiotic relationships explain most genetic variation is still something of a fringe idea (Mann 1992, Wikipedia).

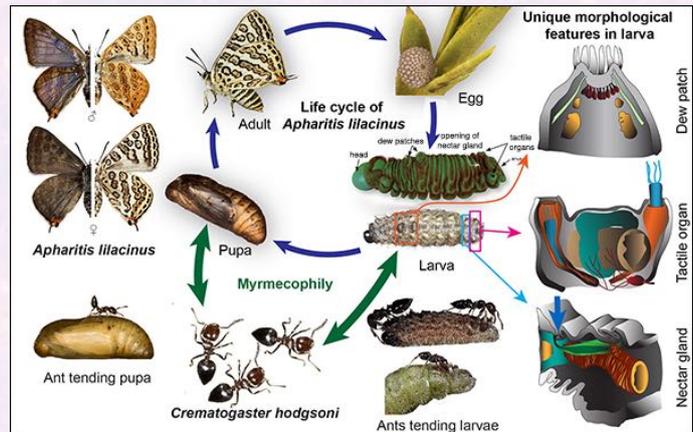

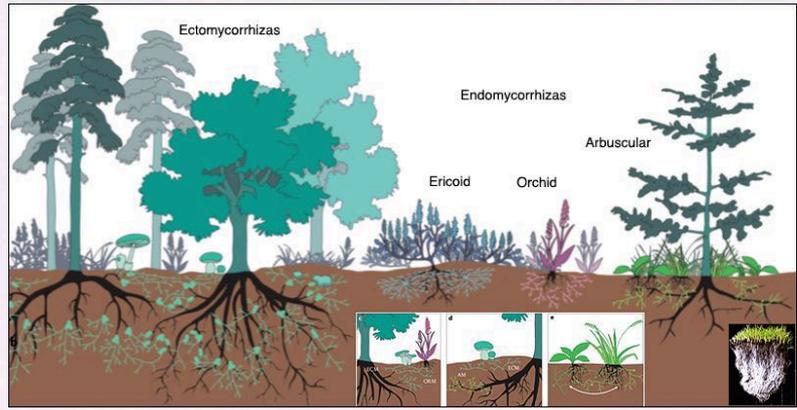

Fig 63c: **Symbiosis** is a prime manifestation of food web, and hence ecological, complexity. (Top left) cleaner fish gain food by cleaning the skins and mouths of larger carnivorous fish, which also keeps the fish free of parasites. Similar symbioses occur with cleaner shrimps and Moray eels, between crocodiles and birds, and with the oxpecker, which cleans parasites from the ox. The usual mutualistic relation between plants and their insect pollinators providing nectar and protein pollen to the pollinator, in return for spreading their pollen, has many dynamical variations, changing the rules. (Bottom left) Frank exploitation of the orchid *Ophrys eleonorae*, whose pollinator a type of bumble bee is purely exploited because it receives no nectar and instead, the orchid accomplishes its sexual deception by mimicking the appearance, scent, and even tactile experience of a female bee, complete with fake fur and what appear to be folded iridescent wings and amid the sexual jostling sticks its pollinia on to the bees' back. Bees have even been recorded ejaculating wasting their sperm (Gaskett et al. 2008). (Centre pair) A peacock's tail arms race often occurs between flowers and pollinators, in which a plant becomes choosy enough to select only one pollinator species, virtually guaranteeing its pollen will go to a plant of the same species. Here *Angraecum sesquipedale* has an exceptionally long nectary (getting on for 30 cm) and in a book on orchid pollination, Darwin suggested that this extreme feature may have evolved alongside a moth with an exceptionally long tongue to pollinate it. In 1907, more than 20 years after Darwin's death, a subspecies of the gigantic Congo moth from Madagascar was identified and named as *Xanthopan morgani praedicta* apparently fulfilling Darwin's prediction (the name indicating that it was predicted). The moth is large at around 16cm in wingspan, but the proboscis is truly colossal and can be more than 20cm in length forming a huge coil in front of the head when not in use. It wasn't until 1992, nearly a century later, that observations were made of the moth feeding on the flower and transferring pollen from plant to plant with both videos and stills being taken. This was observed in the wild and confirmed further with studies in captivity (Ardetti et al. 2012). Right: Oxpeckers in mutualism with Zebra. Carrion beetles symbiotic with mites which eat the eggs and freshly hatched maggots of flies that compete with beetle larvae for their food source. Aphids in symbiosis with ants provide sap nectar "stools" for the ants, while the ants attack and remove ladybug predators.

Margulis also held a negative view of certain interpretations of Neo-Darwinism that she felt were excessively focused on competition between organisms, as she believed that history will ultimately judge them as comprising "a minor twentieth-century religious sect within the sprawling religious persuasion of Anglo-Saxon Biology." She wrote that proponents of the standard theory "wallow in their zoological, capitalistic, competitive, cost-benefit interpretation of Darwin – having mistaken him for ... Neo-Darwinism, which insists on [the slow accrual of mutations by gene-level natural selection], is in a complete funk." (ibid)

Fig 63d: One of the world's greatest symbiotic relationships is the mycorrhizal relationship between fungi and the land plants (Genre et al. 2020). The plant makes organic molecules such as sugars by photosynthesis and supplies them to the fungus, while the fungus supplies the plant with water and mineral nutrients, such as phosphorus, taken from the soil. This can create a very extensive web throughout wilderness areas, in which the fungi serve to mediate competing needs of individual plant species. Fossil and genetic evidence indicate that mycorrhizae are ancient, potentially as old as the terrestrialisation of plants. There is fossil evidence that early land plants that lacked roots formed arbuscular mycorrhizal associations. Genetic evidence indicates that all land plants share a single common ancestor, which appears to have quickly adopted mycorrhizal symbiosis, and research suggests that proto-mycorrhizal fungi were a key factor enabling plant colonisation of the land, although the analogy of a "wood-wide web" is debated (Karst et al. 2023). Similar symbioses occur between legumes and nitrogen fixing bacteria in their root nodules.

Margulis met with Lovelock, who explained his Gaia hypothesis to her, and very soon they began an intense collaborative effort on the concept. One of the earliest significant publications on Gaia was a 1974 paper co-authored by Lovelock and Margulis, which succinctly defined the hypothesis as follows: "The notion of the biosphere as an active adaptive control system able to maintain the Earth in homeostasis we are calling the 'Gaia hypothesis.'" Like other early presentations of Lovelock's idea, the Lovelock-Margulis 1974 paper seemed to give living organisms complete agency in creating planetary self-regulation, whereas later, as the idea matured, this planetary-scale self-regulation was recognized as an emergent property of the Earth system, life and its physical environment taken together (Lovelock 1972, Lovelock & Margulis 1974).

Wolbachia, fig 68 are a genus of bacteria that parasitise arthropod species, including a high proportion of insects, and some nematodes. It is possibly the most common reproductive parasite in the biosphere. As many as 25 to 70% of all insect species are estimated to be potential hosts. Their interactions with their hosts are often complex, and in some cases have evolved to be mutualistic rather than parasitic (Zug & Hammerstein 2015). In the bedbug *Cimex lectularius*, *Wolbachia* provide essential B vitamins and are housed in specialised organs, the bacteriomes. The mosquito *Culex pipiens* is naturally infected with *Wolbachia* and the pathogen *Plasmodium relictum*. *Wolbachia* protects its host against *Plasmodium*-induced mortality. The parasitic wasp *Asobara tabida* depends on *Wolbachia* for oogenesis. *Wolbachia* can alter the hosts' sexual reproduction in multiple ways to enhance their own reproduction and survival, including: (1) induced **male mortality** during larval development, increasing reproduction of infected females, (2) **feminization** resulting in infected males that develop as females or infertile pseudofemales, (3) **parthenogenesis** – reproduction of infected females without males and (4) **cytoplasmic incompatibility** – the inability of *Wolbachia*-infected males to successfully reproduce with uninfected females or females infected with another *Wolbachia* strain.

True symbiosis is usually defined as an evolutionarily stable mutually supportive relationship between species in which each symbiont achieves a better outcome than it would if it defected and exploited its co-species instead. The biosphere contains many examples of such relationships, from the cleaner shrimps servicing moray eels (animal—animal), through lichens (algae/cyanobacterial—fungal) coral polyps (algae—animal) and ants with fungi (animal—fungal—bacterial). However, these relationships can become very complicated, with dynamic evolutionary processes affecting both mutualism and parasitism as illustrated in figures 63b, 63c, 63d 64 and 68.

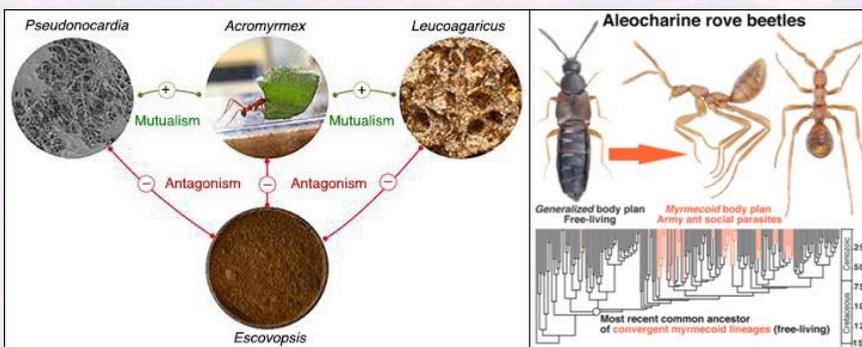

Fig 63e: Left: *Acromyrmex* leaf-cutter ants form a mutually beneficial symbiosis with the fungus *Leucoagaricus gongylophorus* and with *Pseudonocardia* bacteria. Both are vertically transmitted and actively maintained by the ants. The fungus garden is manured with freshly cut leaves and provides the sole food for the ant larvae. *Pseudonocardia* cultures are reared on the ant-cuticle and make anti-fungal metabolites to help protect the cultivar against disease. Parasitic

Escovopsis fungi can overrun the fungus garden and lead to colony collapse. *Escovopsis* upregulates the production of specialised metabolites. These inhibit *Pseudonocardia* and one also reduces worker behavioural defences and is ultimately lethal when it accumulates in ant tissues, resulting in an evolutionary arms race. Right: deep long-lasting symbioses between multiple species of Roe beetle symbionts and army ants whose evolutionary tree displays convergence to such habits going back to a common ancestor in the early Cretaceous 110 million years ago (Maruyama & Parker 2017).

Furthermore, a more general view of indirect or dynamic symbiosis is reinforced by the dynamical relationships between organisms, for example between plants and their herbivore animal parasites and predators and their herbivore prey, where the exploitative relationship belies the fact that the population dynamics of each, with insect

plant predation aiding plant diversity by attacking weedy monocultures and the carnivores avoiding the herbivores entering boom and bust by denuding the landscape of plants they depend on in the absence of predators.

One needs to understand that climax ecology involves increasingly deep and long-lasting symbiotic relations when species interact in ways which benefit both, as illustrated in figs 63c-f. Vertebrate-arthropod symbiosis for example occurred between nest dwelling beetle larvae feeding on feathers from a theropod host (avian or nonavian) 105 million years ago, found in feathered amber as skin/hide beetles (family Dermestidae), an ecologically important group of keratophagous species that commonly inhabit bird and mammal nests (Peñalver et al. 2023). Byrne & Lunn (2019) describe the complexity of elephants and trees mediated by Scarabaeidae – scarabs, or dung beetles, revered as symbols of regeneration in ancient Egypt, whose spoils rolled in a giant ball with great effort by the beetles and buried, improve soil structure and fertility and facilitate regeneration of the seeds of the plant and tree species elephants eat.

Fig 63f: Because major classes of organism adopt characteristic niche strategies they can provoke the evolutionary emergence of a reactive class of prey. Carnivorous ants have a major world-shaping influence on wild ecosystems, consuming insects in their path. In response, the *Lycaenidae*, the second-largest family of butterflies with over 6,000 species worldwide (about 30% of the known butterfly species) have developed a long-term symbiotic relationship with ants, in which they provide nutrient in return for not being attacked and being able to consume plants in the ants territory. The larvae are often flattened, with glands that may produce secretions that attract and subdue ants. Some are capable of producing vibrations that are transmitted through the substrates they inhabit and use these sounds to communicate with ants even causing them to think they are an alarmed queen. Several evolutionary adaptations enable these associations, including small glands on the skin of the caterpillars called "pore cupola organs". Many species have a gland on the seventh abdominal segment that produces honeydew, as do aphids which are "milked" by ants, and a cylindrical "tentacular organ" is present on the eighth abdominal segment and this is topped with a ring of spikes and emits chemical signals which are believed to help in communicating with ants. In some species, larvae are attended and protected by ants while feeding on the host plant, and the ants receive sugar-rich honeydew from them. In some species like the large blue *Phengaris arion*, the majority of the larval lifespan is spent as a predator within the ant nest. It becomes a parasite, feeding on ant regurgitations, or a predator on the ant larvae, turning the tables on the symbiosis, to exploit it having long ago evolved to seduce the ants.

There are of course outstanding examples of competitive survival of the fittest in evolution. Genetic systems as simple as transposable elements and simple molecular viroids, such as the potato spindle viroid fig 64, display competitive life cycles, giving rise to the notion of the "selfish gene" (Dawkins 1976). Competitive survival also resounds in male sexual combat, ensuring genetic fitness of the resulting offspring. Competition also occurs between predator species, as illustrated fig 64 right, in cheetahs stealing from a lion. Hence competition, predation and parasitism and symbiotic mutualism form complementary strategies, all of which are essential to climax diversity.

The lesson from this, in naively simplistic mathematical terms, is that predators appear to be destructive to the herbivores, but actually ensure their long-term survival, by avoiding genocidal famines. Out on the savannah, these seasonal oscillations may be less predominant, and wet and dry seasons and the vagaries of the climate will also cause fluctuations. The carnivores tend to opportunistically take out stragglers, and some of the young and old, so we rise to a climax of interacting species.

Many of the most outstanding features of tooth and claw that give us the image of the brutality of nature actually abet biospheric symbiosis. Robert May (1976) used the logistic iteration to model a rabbit population X_i eating the remaining grass $1 - X_i$ and we get $X_{i+1} = rX_i(1 - X_i)$. Depending on the reproduction rate r we get equilibrium, period doubling, and chaos, which eventually disrupts in a high chaos bust at $r = 4$, where the population hits unity, consuming all the grass and then zero in extinction. This shows that two component herbivore-plant ecosystems are intrinsically unstable to lethal oscillation of the herbivore. When we include herbivore predators, the Lotka–Volterra equations give us precipitous but sustainable oscillations, as growing carnivore populations assimilate the herbivores to low levels, leading to seasonal rebounds in each. Other population dynamics can become chaotic. Rogers et al. (2021) show that chaos is common >30% in natural ecosystems.

The same picture is occurring with plant evolution. The rise of plant climax diversity is symbiotically moderated by the wide spectrum of herbivorous parasites and predators. This idea of repulsion – formally known as conspecific negative density dependence, or CNDD – goes back to the 1970s when the ecologists Daniel Janzen (1970) and Joseph Connell (1971) independently suggested that insects, herbivores and pathogens that prey selectively on one species could make the area around an adult tree dangerous for its seeds. The reason weedy plants don't rule the Earth is because insects, animals and fungal, bacterial and viral diseases all selectively target massive distributions of genetically similar material. The grasslands are subject to plagues of locusts. Diseases likewise target predominant species. Thus plant

diversity, although also aided by environmental variance (Fung et al. 2016), is critically driven by insect predation, which explains why rainforests reach climax diversity rather than dominance of weedy species.

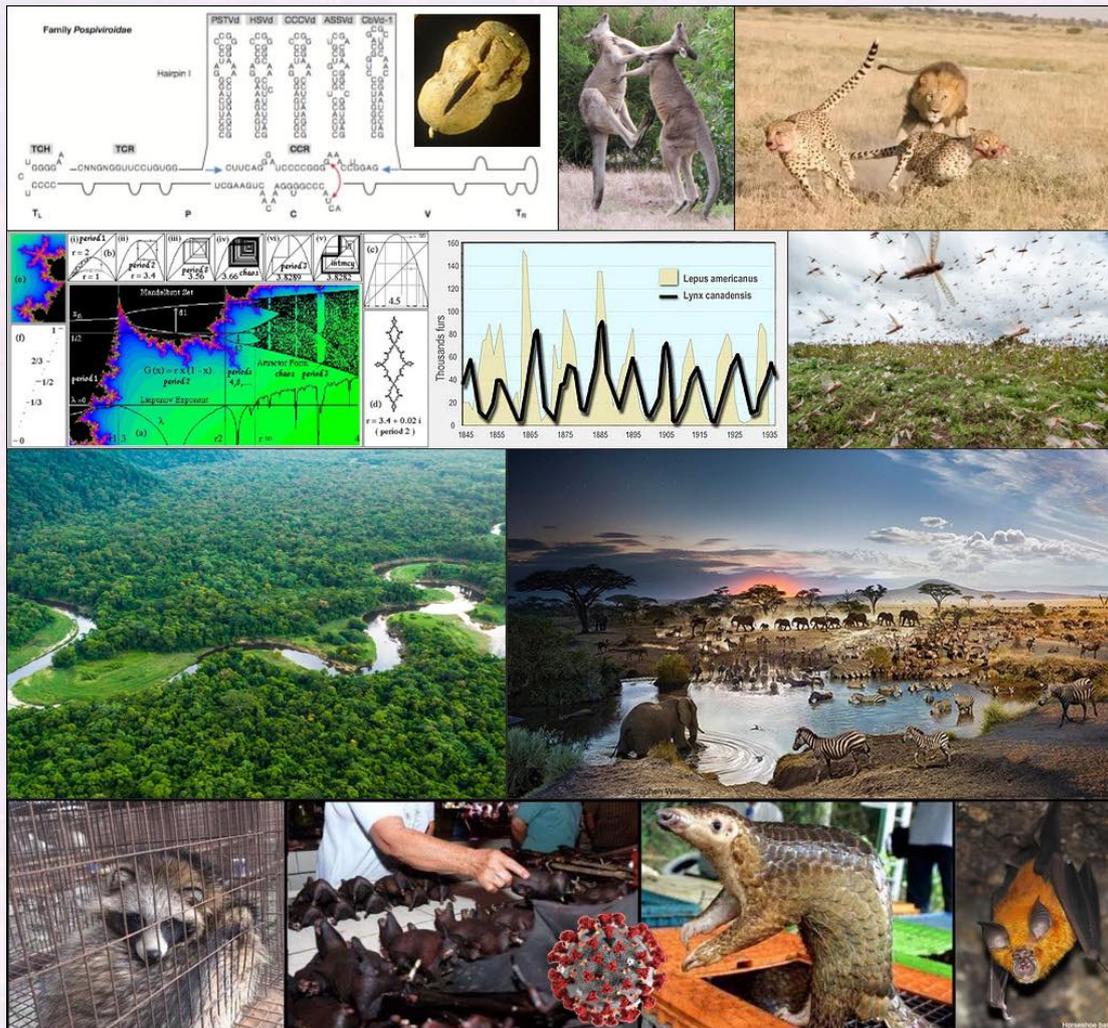

Fig 64: **Biospheric Symbiosis:** Top: Potato spindle viroid exemplifies competitive fitness in a single RNA molecule. Two male kangaroos in sexual combat. Cheetahs stealing meat from a lion. Second row: Logistic equation for rabbits in a finite pasture reaches chaotic instability leading to boom and species extinction bust. Lotka–Volterra equations between lynx and rabbits show coupled stable oscillations over 10-year seasons. A locust swarm consumes dominant vegetation. Third row: Climax plant diversity in the rain forest and large mammal diversity on the savannah. Bottom: The corona virus pandemic was caused by human misadventure, in a symbiotic bat virus becoming pathological by forcing wildlife together in unnatural conditions, leading to mutational species jumps.

Although plants also engage inter-individual and inter-species competition, Forrister et al. (2019) tested two mechanisms thought to underlie negative density dependence (NDD): plant competition for resources and attack by herbivores and confirm that it is the load of insect predation which results in the related species separation of climax diversity. After a long undisturbed period, wilderness habitats thus reach climax biodiversity because the overall interactive species-specific forms of natural and sexual selection promote maximal genetic symbiosis and optimal species diversity. Kalyuzhny et al. (2023) show that in comparison to a null model of stochastic birth, death, and limited dispersal, the adults of dozens of tropical forest tree species show strong spatial repulsion, which can occur only if CNDD considerably exceeds heterospecific negative density dependence – an even stronger condition required for coexistence – and that large-scale repulsion can indeed result from small-scale CNDD.

Biospheric symbiosis: Ultimately every species is able to survive only in relation to its viability in the biosphere in relation to the other existing organisms. Organismic symbiosis is then realised in biospheric symbiosis of each species within the biosphere as a whole, in which natural and sexual selection is a measure of survival of the most successfully symbiotic species within the biosphere, whether parasites, prey, predators or hosts through the long term dynamics of social survival within the enclosing planetary circle. As noted, predators, although epitomising homicidal aggression, function to stabilise the biosphere from unstable fluctuation, by taking out the herbivore stragglers, avoiding the herbivores eating out their food supplies and starving in a boom and bust. *Homo sapiens* is the first species to exist on

the planet and globally disrupt and exploit and violate the symbiotic climax of life evolving through habitat destruction, climate crisis and sheer overpopulation.

But the buck doesn't stop there. The Corona virus pandemic occurred because of human impact on animals harbouring Corona viruses, forcing wild animals into close contact with other species, which would not occur in the wild, that gave rise to a new disease, when bat corona viruses, which are in a symbiotic relationship with bats, were knocked out of their symbiosis and became a world plague, affecting not only humans, but massive numbers of mink in dense mink farms and even rhinos. Bats roost in vast "urban" cave communities, where multiple pathological diseases, from rabies to corona viruses, occur endemically. Bats have figured out how to dampen down the corona presence to an asymptomatic level using interferons. With the rise of the Omicron variant, involving recombination with other corona virus elements, the pendulum is potentially swinging back to endemic symbiosis. Thus again the plagues and pestilences we abhor as the worst aspects of nature in the raw are actual vectors of symbiotic climax.

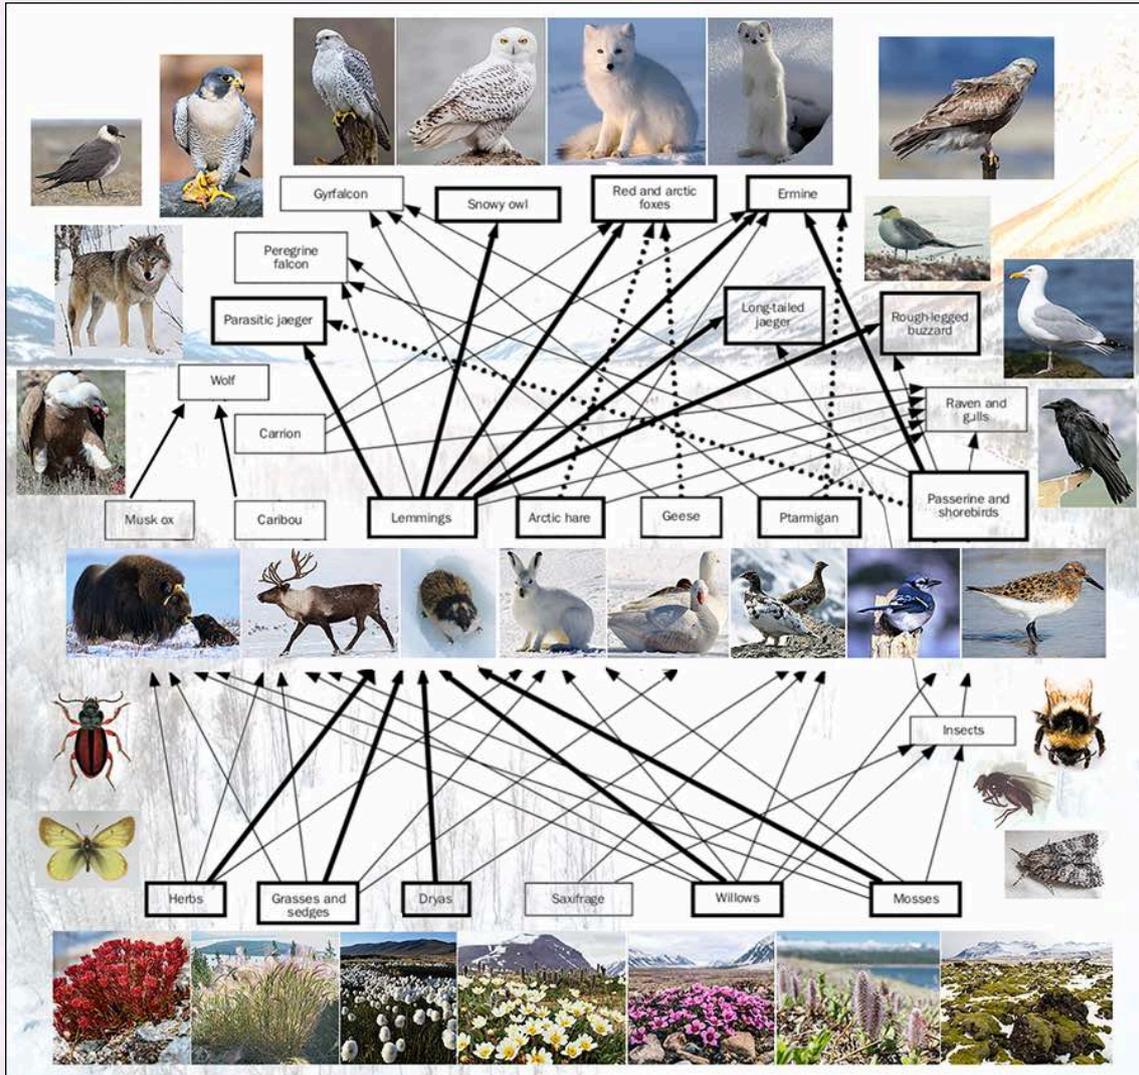

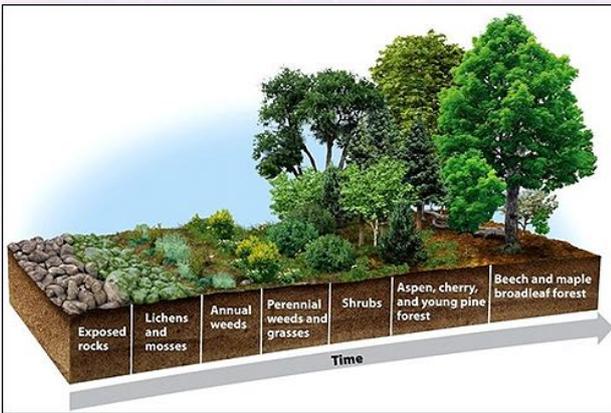

Fig 64b: Climax ecology food web of the Arctic tundra illustrates how interactive species relationships come to sustain a complex thriving ecology, in which plants, herbivores and carnivores all form an integral whole in biospheric symbiosis (Ims & Fuglei 2005). As we speak, the high tundra is losing its whiteness and turning green due to climate change, threatening all these fragile ecological relations and the very survival of these species (Rawlence 2022).

Ultimately, **society** and **culture** are also manifestations of symbiotic survival, however human emergence has been fraught with species-focused selection, leading to **egotistical consciousness**, tribal and civil warfare, as well as **sexual wars of dominance** between the male and female sexes, in which **patriarchy** has compromised the sexual prisoners' dilemma, inhibiting female reproductive choice essential for XY-based evolution and breaching human equilibrium with the biosphere, in exponentiating **devastation of the natural habitats** of the planet, **climate crisis** and **resource crisis**.

No matter what pretensions we have to technological, scientific, cultural, intellectual or even spiritual ascendancy and dominion over over nature, we are and remain biological mammals, who depend on other living species, to eat like

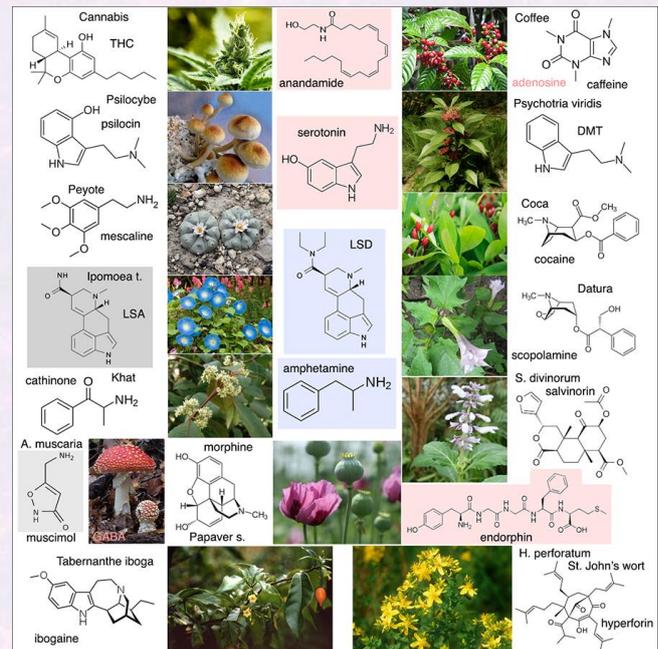

other mammals do to survive, for our medicines, and ultimately for the entire viable biospheric and climatic environment in which we exist and even the oxygenated air we breathe. We evolve as other species do, notwithstanding utopian notions of genetic engineering. Culture and intellect are extremely rapid and fundamentally unstable processes, which provide no conceivable survival tenure on evolutionary time scales. We thus survive as a species through our relationships with the biosphere and its living diversity on which we remain utterly dependent.

Fig 64c: The primary succession from weedy plants to large shade tolerant climax forest takes hundreds of years to establish.

(e) **Psychic symbiosis** with entheogenic species is a well-established reality. Although traditional use of mushrooms and peyote has tended to involve collection from the wild, since their rediscovery, sacred mushrooms have become symbiotically cultivated worldwide. *Cannabis indica*, *Papaver somniferum* and *Erythroxylon coca* have each had several millennia of cultural cultivation. *Salvia divinorum* originated in the Oaxaca region of Mexico, where it has been cultivated and used for centuries by the Mazatec people as a healing herbal remedy including Maria Sabina herself, and in religious ceremonies. The species has so adapted to being kept as hidden cultivars, that an event after the pollen tube reaches the ovary is aberrant and no fully developed nutlet has been collected from a Mexican plant.

Fig 65: A spectrum of natural psychoactive substances are all of optimal activity and not superseded by synthetics except for LSA in morning glory which is superseded by LSD and to a certain extent muscimol is eclipsed by GABA-ergic Z-drugs. This illustrates efficient but incomplete biospheric evolution of psychoactives. Pink: corresponding natural neurotransmitters. Blue: synthetic pharmaceuticals.

Fig 65 shows a variety of species bearing psychoactive substances. Certain synthetic molecules such as selective serotonin uptake inhibitor (SSRI) anti-depressants, which inhibit serotonin transporters and tricyclics are absent, but, apart from the lysergic acid amide (LSA) in *Ipomoea*, these substances are optimal, in the sense that no synthetic drug has effectively superseded them and many remain essential medicines. Many of these species have probably derived their phytochemicals as defences against insect predation, as we have seen with the gene complex for psilocin.

Most are receptor agonists, or antagonists, for example the psychedelics psilocin, dimethyl-tryptamine (DMT) and mescaline are serotonin 5HT_{2a} receptor super-agonists, but cocaine inhibits dopamine transporters increasing pleasure and alertness and cathinone has similar stimulant effects to amphetamine by activating the trace-amine receptor (TAAR1) responsible for regulating dopamine and nor-epinephrine levels via transporters. By and large those synthetics which transcend the activity of these natural substances, from methamphetamine to fentanyl and synthetic cannabinoids, have markedly more damaging social effects. Even cocaine in its natural context is a revered spiritual ally, for example the Kogi of the Andean cloud forest, who use coca as their principal spiritual ally, believe that natural coca civilises men. Nicotine in tobacco (not included in the figure) agonises nicotinic acetyl choline receptors, while scopolamine antagonises muscarinic ones. Morphine agonises μ - δ -opioid receptors while salvinorin-A agonises κ -opioid receptors. THC partially agonises CB₁, CB₂ anandamide receptors in neurons and neuroglia. Caffeine antagonises adenosine receptors, blocking effects of fatigue.

This is an expression of symbiotic edge of climax. This doesn't mean that entheogens are an exclusive route to the cosmic mind, but they are in my view sang raal – royal blood of the biosphere for our insight. Just as the fractal molecular structures of the H–CNO bio-elements are a sang raal of biogenesis, the entheogens are sang raal of biospheric union – a genuine spiritual experience evoked by union with and interdependence with other species.

The prosocial effects of psilocybe species have even been proposed to have played a role in the emergence of human culture (Rodríguez & Winkelmann 2021). The natural correction to this scenario comes from the complex sensitivity of conscious existence **not being the exclusive dominant possession of a single species *Homo sapiens***, but is achieved in **psychic symbiosis**.

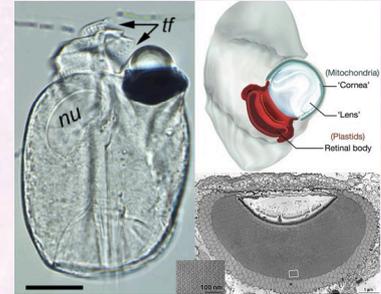

Fig 66: An extreme example of single-celled eucaryote adaption to a quantum mode. The dinoflagellate *Nematodinium* possesses an ocellum forming an eye, with a retina made from coopted chloroplast light sensors and a lens with inset wave plate made from mitochondrial membranes (Gavelis et al. 2015).

Of course this is not the exclusive or only route to moksha. We can also do deep transcendental meditation, but full blown moksha is rare and generally a more controlled experience of union, which tends to invoke mind-sky mysticism in which humanity remains the dominant pinnacle of divinity under deity. In some religions such as the Jains, all life is revered but it is linked to the idea of reincarnation and the life forms are simply sentient beings rather than genetic biological organisms. Reincarnation is really an opt out clause for the rarity of moksha based on the moral law of karma. And yes it is also a manifestation of the animistic inclusion of souls of all beings which is good. But entheogens are prima facie empirical psychic symbiosis because moksha is achieved in sacred interaction with another species, closing the biospheric symbiotic circle.

Fig 67: **Devoted parenting**: Upper: (1) Jumping spider guarding her young. (2) Squid guarding her egg pouch. Carrying an egg mass of 2,000 to 3,000 eggs and hatchlings for six to nine months can make swimming difficult for *Gonatus onyx* squid mothers. (3) The Golden Brown Stink Bug mothers guard not only the eggs, but also the 1st instars until they become 2nd instars. Lower: (4) Cichlid fishes have evolved into over 1500 species in the isolated lakes of the Great Rift Valley. Competition is fierce, and this mother shelters her offspring in her mouth at any sign of danger and takes them to a safe spot to release. They may also become invaded by cuckoo catfish (fig 68). (5) Hierarchical rank of female dominant hyenas is a key social feature of survival. At 12 weeks young hyenas need to learn to observe the rank of all 60 in the clan. Here an alpha female with two young offspring, teaches them to extract a head-bobbing concession from an older adolescent of lower rank (BBC).

Cosmological symbiosis. Psychic symbiosis provides a basis for cosmological symbiosis (see fig 58) recognising that symbiosis is a foundational principle of the interactive consummation of the physical universe, invoked as a key manifestation of complementarity, evident in the eucaryote symbiosis between archaea and bacteria, sexual complementarity, and the symbiotic relationship between all living species and the biosphere as a whole, on which we all co-depend. This then becomes extended in the following description as a cosmological principle, both in psychic

symbiosis with entheogenic species and the ensuing symbiosis between the organismic and cosmic mind and between the cosmic mind and the physical universe as a result of human symbiosis with the cosmos, leading to planetary reflowering and abundance over evolutionary and cosmic time scales.

A key element of this description is that it gives a succinct, biologically realisable account of how the subjective aspect of reality i.e the panpsychism in quanta becomes coherently evoked in living systems, revealing a coordinated functional relationship with the physical universe.

This is a three stage-process, **(1)** with the formation of **excitable cells** in both archaea and bacteria. **(2)** with the symbiosis between archaea and bacteria to form complex eucaryote cells we reach the emergence of **cellular consciousness**. With cell organelles and nuclei, the excitable eucaryote cell gains the full edge-of-chaos sentience associated with physical quantum modes, from light, molecular vibration and the perturbation of chemical orbitals on the excitable membrane, leading to sensory organelles, social signalling, epigenesis and genetic evolution modified by cellular sentience. This is where the major quantum leap of consciousness takes place. **(3)** We reach **organismic consciousness** through dynamic elaboration via neuronal coupling in multi-celled organisms, and genetic diversification of function with increasing organismic complexity, we arrive at the conscious brains of organisms, utilising coupled cellular sentience, as manifested in our subjective consciousness accompanying brain dynamics. This has in turn induced an explosive increase in complexity so that the human brain has around 10^{10} neurons with 10^{15} synapses, an intimately coupled society of amoeba-flagellates, forming a massively parallel quantum computer, making transitions at the edge of chaos (King 2014) involving quantum measurements of its own wave excitations, through discrete pyramidal action potentials timed to the progression of wave coherence (Qasim et al. 2021) as highlighted in fig 78. This complexity has in climax species from humans, through dolphins to elephants reached a cosmological level unknown elsewhere in the universe than in the biota.

Fig 68 **Parasitic coevolution** can be viciously predatory but also innovatively symbiotic. (1) Parasitic horsehair worms *Chordodes formosanus* that dwell in the guts of praying mantises compel their hosts to walk to water, by stealing chunks of their their hosts' genome in massive horizontal transfer (Mishina et al. 2023), producing a molecule that causes them to march toward light shimmering off water and drown themselves, where the worms can reproduce and enter new nymphs. (2) The cuckoo catfish lay their eggs alongside those of mouth-parenting cichlids of fig 67 eating as many cichlid eggs as possible as a gang, so the cichlid mother ends up with some intruders, and like cuckoo bird hatchlings eradicate competition, they eat the cichlid babies and take over while the

cichlid mother continues to nurture them. (3) The isopod crustacean *Cymothoa exigua* parasitises this clown fish's tongue. These organisms are protandric hermaphrodites that start their lives as males and switch sexes later in their life cycle. The isopod that attaches to the tongue is or becomes female, while a subsequent male attaches to the gill arches beneath and behind the female until they move forward to fertilise her when she is ovulating. Using its front claws, *C. exigua* severs the blood vessels in the fish's tongue, causing the tongue to necrose from lack of blood. The parasite then replaces the fish's tongue by attaching its own body to the muscles of the tongue stub. The fish then survives remaining relatively healthy if not doubly infested, but depends on the isopod to survive and eat while it lives off the fish's mucus or blood scraps. (4) An amber snail infected with the green-banded broodsac worm *Leucochloridium paradoxum* crawls into the eyestalks of snails, takes over its brain then pulsates to make the mollusk look like a dancing caterpillar to attract birds to eat them. A similar strategy to *Toxoplasma gondii* which affects rodent brains to make them fearless of cats. 30-60% of humans are infected, have longer reaction times and become less careful as drivers, having a 2.6 times higher risk of accidents (Flegel et al. 2002). (5) *Wolbachia* bacteria in *Drosophila* (orange) with DNA (green) are transmitted in the ova using the host microtubules (Ferree et al. 2005). *Wolbachia* are parasitic but can also evolve to be mutualistic (Zug & Hammerstein 2015) providing hosts with essential nutrients, disease resistance and reproductive options. (6) Ants of the species *Temnothorax nylanderii* show exceptionally high survival rates when infected with a tapeworm (inset). Such workers are favourably tended by the workers and have adolescent pheromones promoting nurturing, giving them a survival longevity similar to queens, which can live for up to 20 years, while female workers rarely reach the age of two. The ants serve as an intermediate host for the tapeworm *Anomotaenia brevis*, whereby a single ant can be infected by up to 70 parasitic larvae. The parasites survive in the hemolymph body fluid of the insects. Their complex life cycle is completed once they have been ingested by a woodpecker that feeds on the ants, to become an adult tapeworm.

"The fact is, I don't even know that you're conscious.

The only thing I know beyond any doubt—and this is one of the central insights of Western philosophy—is *Cogito ergo sum*.
What Descartes meant is the only thing I'm absolutely sure of is my own consciousness". (Chris Koch)

“My own view is that consciousness is intimately tied to our nature as living flesh-and-blood creatures. In this picture, being conscious is not the result of some complicated algorithm running on the wetware of the brain. It is an embodied phenomenon, rooted in the fundamental biological drive within living organisms to keep on living. If I’m right, the prospect of conscious AI remains reassuringly remote” (Anil Seth *Why Conscious AI Is a Bad, Bad Idea* 2023).

Just as we don’t directly perceive the subjective consciousness in others, but infer it in their lively, purposeful behaviour, in a combination of sentience and volitional will, which we sense we can subjectively identify as conscious, cellular subjective consciousness is universal but unrealised. We see subjective consciousness more easily in other mammals, such as our pets, but we also see it in the creatively extraordinary songs and mating dances of birds and spiders [fig 113](#) because here sexual selection hones the sheer creativity of evolution through mate choice. We also see it in parenting and cooperative social activity in animal societies. We can also experience subtle expressions of conscious purposiveness in the collective mating songs of crickets in the field, and in the synchronised flashing of fireflies.

“The agency of all sorts of creatures is the most fascinating, self-explanatory, self-manifesting thing and phenomenally and experientially the most indubitable fact in the world”
(Vetlesen “The Cosmology of the Anthropocene” 2019).

And evolution shows us that these patterns of purposive activity run all the way down the evolutionary tree to the first single-celled eucaryotes. Dictyostellium are single-celled free-living amoeba that show individual purposiveness in their feeding behaviour and have extensive behavioural and genetic homology to our neutrophil phagocytes [1](#), [2](#). [Dictyostellium slugs](#) also show coordinated purposeful behaviour in a highly active colony of a thousand aggregated myxamoeba. These are electrically excitable, pluripotent, motile stem-cells, engaging coordinated, motile actions and clear decision-making manoeuvres as a consensual organism. This is an organismic manifestation of cellular consciousness in action even though myxamoebae have only graded potentials. Individual amoeba likewise show purposeful activity very similar to human macrophages. This is the closest we can come to a scientific verification of the kind of consciousness we associate with higher animals in social single celled eucaryotes.

The problem facing verification is not that the complementary subjective aspect is fuzzy or vitalistic, or ill-defined, but that, by its very subjectivity it is not objectively evident just as we don’t see one another’s consciousness directly and it non-local and largely indivisible, as Buddhist philosophy suggests, forming encapsulated instances of a phenomenon complementary to the universe as a whole. Replication is thus achieved not through objective observation, but veridical verification by empirical experience. This is straightforward with other humans by mutual affirmation, but very difficult with single-celled species and even more so with individual quanta, which manifest subjectivity only through idiosyncratic individual particle trajectories which approach statistical average in the wave amplitude.

No matter how subtly we try to monitor brain states, and unravel their biology, chemistry and physics, including edge-of-chaos dynamics and quantum effects, subjectivity cannot be conjured up by an objective interaction of purely objective structures. No assembly of objective elements that has no subjective components can have subjective existence. We may find a dynamic structure of excitons, just as we do in subtle quantum experiments, such as weak quantum measurement and quantum entanglement, but none of these complex structures will have subjective nature if none of the elements do, as we learn from the failure of complex digital systems to demonstrate verifiable features of subjective existence. Therefore a purely objective description founded only on the brain is categorically intractable and incomplete. On the other hand, all physical experiences of the world around us are actually consensual forms of conscious experience, so it is clearly possible to construct a complete cosmology from consensual conscious experiences. A complementary description in which consciousness and the physical universe co-exist can thus solve the hard problem, while retaining all the empirical features in brain dynamics key to a biological realisation of the Cartesian theatre (Baars 1995, 1997). At the same time it resolves the quantum measurement problem through the subjective aspect collapsing the wave functions of the probability multiverse. Moreover the symbiotic cosmology depends only on the current status of the [core model](#) of physics, and the standard probability interpretation of the wave function, and does not need to invoke the anthropic cosmological principle (Barrow & Tipler 1988) although this is obviously consistent with it.

Both a purely physical cosmology in which human actions are ruled by [mindless physical circumstance](#) and religious cosmologies ordained by the [will of God](#) or cosmic consciousness itself, place fundamental impediments on our personal autonomy. The materialist physical world view regards consciousness as merely an internal model of physical reality constructed by the brain and volitional will as a delusion having no real effect on the physical world. The

religious view asserts that we do possess free will, but casts the entire universe as a moral test for God's will under pain of dire punishment. The only way out of this dilemma is that subjective consciousness has an effect upon the world at the level of fundamental physics. In the symbiotic cosmology volitional will has a real part in determining the course of history, thus verifying our veridical autonomy of decision-making, i.e. free will, validating and completing our experience of the world around us. Indeed only in such a cosmology can personal autonomy have any real meaning.

Since we know we no longer exist in a flat Earth universe with beaten-dome firmaments, deity or its alternatives have to be envisaged in more subtle ways, as something that stands outside and beyond the universe but shapes it in some manner outside physical cosmology. It is also extremely unlikely that a God who created the universe as we now know it, with symmetry-breaking forces, galaxies permeating the heavens, and on Earth, evolution leading to climax genetic diversity, including parasites and hosts, predators and prey, did so as a simple moral test of obedience. But we do know that the one and only tangible entity that stands outside and beyond the objective physical universe is subjective conscious existence itself. In fact all religious notions, such as Heaven and Hell are consciously envisioned realms, just as animist spirit realms are conscious visionary experiences and all personal religious experiences of deity, that are not simply religious doctrine taken on faith, including all mystical transformative encounters come as conscious and generally visionary experiences.

All realisable hope of a tangible "deity" existing thus now resides in the realms of consciousness. Panpsychism also explains how "God consciousness" could arise as a conscious interaction with the universe as a whole. This is the same concept as the atman becoming one with Brahman in Indian spiritual philosophy. We have to accept that if such interaction is unreal, then tangible interaction with any form of "deity" is unreal. However if the panpsychic postulate is true then the mind at large has reality as the fully manifest form of the subjective aspect existence on a cosmic basis and then our individual conscious existences are extant as functionally encapsulated instances of the mind at large.

There are fundamental evolutionary reasons why the entheogenic species are bound to occur and why they may be able to induce a form of "primary consciousness" evoking cosmic consciousness or the mind at large, as a result of evolution in a universe governed by fractal laws of nature.

The core neurotransmitters involved are modified elementary amino acid amines going back to the origin of life. Their pathways have been conserved since the foundation eucaryotes, as social signalling molecules, to provide feedback modes ensuring the survival of the collective organism. The brain is effectively a close-knit social organism of neurons and neuroglia communicating almost exclusively through neurotransmitters, with the core pathways, such as serotonin and dopamine continuing to have key conserved survival-related modes to ensure a purely electrochemical brain doesn't deviate from organismic survival. Evolution has honed this by natural selection, so that these modes, as expressed in the default mode network and others, focus on an emotional and cognitive dynamic that gives rise to what we consciously experience as ego. However, this has proven not to be hard wired, but like the senses, is adaptive. Moreover the highly-conserved evolutionary role of serotonin in development from social amoeba to the human brain noted above means that the ancient roles of serotonin in development may maintain evolutionary forces in humans also favouring serotonin and other target neuronal circuits to favour collective, rather than individual survival.

Because individual consciousness is actually an encapsulated form of cosmic consciousness, modified forms of these neurotransmitters produced by other species among them *psilocybe*, *lophophora* and *psychotria*, are able to tweak the serotonin 5HT2a receptor system in such a way as to impede "secondary consciousness", as in the DMN, allowing the conscious brain to revert to an ego-dissipated form of "primary consciousness". It appears that, simply by doing so, a form of long-term potentiation results, which has lasting beneficial effects, by allowing the individual to "no longer see through a glass darkly", in Paul's words, but now "face to face, knowing even also as we are known".

This makes the notion of unfolding from encapsulated individual consciousness into the universal cosmic consciousness of the mind at large, clearly and unambiguously identifiable with the traditional notion of moksha – escaping the round of birth and death of mortal existence in union of Brahman and atman and in Buddhist satori³³. The Upanishadic notion of atman or inner self, which can become united with Brahman the cosmic self, provides a central vision of this unification. However in the Buddhist perspective, the reality of the self is transcended by the unbroken wholeness and essential voidness of undivided consciousness central to the ability to experience moksha, which requires an approach where there is no dualistic distinction between subjective and objective aspects. Psychic

³³ satori – sudden enlightenment Oxford Lang. See also *subitism* derived from the French *illumination subite* (sudden awakening).

symbiosis is again a complete realisation of the Shakti-Shiva tantra. As noted in fig 259, the moksha epiphany "is not something you can experience from without, neither is it something just within in the heart's desire", but arises when you completely "let go and give your consciousness back to the universe".

The Chan/Zen notion of Buddha-nature, encompasses the idea that the awakened mind of a Buddha is already present in each sentient being. This Buddha-nature was initially equated with the nature of mind, and meditations introspecting on perceiving the mind as a mirror, but this was challenged by Hui-neng in the Zen doctrine of no mind:

*The body is the Bodhi-tree.
The mind is like a mirror bright;
Take heed to keep it always clean
And let not dust alight.
Shen-hsiu*

*There is no Bodhi-tree
Nor stand of mirror bright
Since all is void,
Where can the dust alight?
Hui-neng*

The idea of the immanent character of the Buddha-nature took shape in a characteristic emphasis on direct insight into, and expression of this Buddha-nature. It led to a reinterpretation of Indian meditation traditions, and an emphasis on the idea that the teachings and practices are comprehended and expressed "suddenly" – "in one glance", "uncovered all together" – "together, completely, simultaneously", as opposite to gradualism, the original approach which says that following the dharma can be achieved only step by step, through an arduous practice, possibly taking several lifetimes. This attests to the validity of entheogenic experiences giving sudden insight of lasting value, contradicting the mistaken notion that genuine enlightenment can be achieved only through a supreme effort of dispassionate top down control through mindfulness and suppression of ego in favour of compassionate equanimity.

Fanaa (Arabic: فناء fanā') "to die before one dies" in Sufism is the "passing away" or "annihilation" (of the self). Some Sufis define it as the annihilation of the human ego before God, whereby the self becomes an instrument of God's plan in the world (Baqa). Other Sufis interpret it as breaking down of the individual ego and a recognition of the fundamental unity of God, creation, and the individual self. Persons having entered this enlightened state are said to obtain awareness of an intrinsic unity (Tawhid) between Allah and all that exists, including the individual's mind – being united with the One or the Truth. This second interpretation is condemned as heretical by orthodox Islam. al-Hallaj was crucified when he cried: "ana al-Haqq - I am the truth" and preached overthrow of the Caliphate:

*I am He whom I love, and He whom I love is I: We are two spirits dwelling in one body.
If thou seest me thou seest Him, And if thou seest Him thou seest us both"
(al-Hallaj Armstrong 1993 263).*

Moksha also lies at the source of shamanism and visionaries who initiate and inspire major religions, as exemplified by Yeshua's statements in the Gospel of Thomas – "the kingdom is inside of you, and it is outside of you. When you come to know yourselves, then you will become known, and you will realize that it is you who are the sons of the living father" (3) – "It is I who am the light which is above them all. It is I who am the all. From me did the all come forth, and unto me did the all extend. Split a piece of wood, and I am there. Lift up the stone, and you will find me there" (77). The "ultimate reality" experienced in quantum change experiences also has parallels with the Christian Holy Spirit.

Because psychedelics play directly into the visionary state, in an intense, but consciously negotiable experience, with outstanding transcendent features, it is natural that they should be regarded as central tools, *sine qua non*, in the discovery process of the central enigma of existential cosmology – the role and function of consciousness in the universe, complementing projects such as the LHC seeking to elucidate the foundations of physical cosmology.

Erwin Schrödinger (1944) in dealing with the paradox of many minds in one world stated:

*"There is obviously only one alternative, namely the unification of minds or consciousnesses. Their multiplicity is only apparent, in truth there is only one mind." "Mind is by its very nature a *singulare tantum*³⁴. I should say: The overall number of minds is just one. I would say it is indestructible, since it has a very peculiar time table, namely mind is always now. There is really no before and after for mind. There is only a now that includes memories and expectations"*

Symbiotic cosmology was prefigured in George Greenstein's "Symbiotic Universe" (1988), echoing and extending the cosmological anthropic principle that the existence of the universe depends on its laws being compatible with living observers (Barrow & Tipler 1988):

³⁴ *singulare tantum* a noun which appears only in the singular form – objects which may in principle be counted but are referred to as one.

But the symbiosis to which I am referring here is different. It is of an entirely new sort. The first partner in this new interdependency is not an organism at all, but rather an inanimate structure. Furthermore, it is a structure not previously suspected as taking part in such relationships: the universe as a whole. The second partner in turn, to which to which the first is inextricably conjoined, is alive, but it is not any particular organism. It is not even an entire species. Rather, the second partner is all organisms — life itself. The proposal is that life and the universe are melded into an immense symbiotic unity, and that this is so for reasons that are ultimately metaphysical. Why did the cosmos bring forth life? It had to. It had to in order to exist.

The reality of the mind at large is consistent with the biological and physical reality of a human brain in a transformative state where the brain processes supporting consciousness are freed from their boundary constraints and become unbundled from subject-object polarisation. Since the only manifestations of subjective consciousness we know of in the universe are the biota, organismic consciousness, particularly in such mental states may be the key and perhaps only realisable way that cosmological consciousness of the universe at large can become fully manifest.

We know that the Cartesian theatre of the global workspace of consciousness (Baars 1997) is a complex affair. It is not just the external senses of sight, sound, touch and smell which mediate varying quantum modes – photons, phonons and molecular orbital perturbations. It includes emotions, bodily sensations, trains of conscious thought, involving semantic, symbolic and auditory dimensions. Thought is visual, verbal and abstract. We know we experience these subjective modes together, as a totality, in the midst of a dynamic encounter in the real world. But we also know we can experience intense situations in dreams that are perceived as real rather than merely imagining something. We also experience visionary states which may have complex scenes and encounters, but also other more exotic abstract or ecstatic states of consciousness, unbound from these same constraints also having veridical reality value and that these can approach a state of moksha. Some aspects of our sentience are also shaped by the varying types of receptors for each of the senses, and the way these are processed in wave excitations and action potentials in the nervous system.

This makes it obvious that major aspects of the form of our conscious life and of our brain processing shape the human nature of consciousness. What is critically at stake is the foundation subjective nature of experiential consciousness, complementing the physics, not the particular human evolutionary design of the encapsulation. It is obvious that, even for a person in a state of samadhi, their cosmic consciousness is appearing through a human viewpoint. For example we more easily identify with mammals as we share their limbic system emotions and find arthropods more alien.

On the other hand, we have seen that the key transition in the emergence of subjective consciousness is the founding eucaryote cell. This means that both the features of neuronal excitation and the roles of neurotransmitters are widely shared across all metazoan phyla, with some secondary variation. Thus the physics evoking subjective consciousness in an arthropod, or an octopus is fundamentally homologous to ours, despite major differences in neural circuit design. A key example is the role of serotonin, where we find it maintains the development of the fruiting body sporulation tip in *Dictyostellium*, and likewise plays in humans the role of a fundamental organiser of human brain structure, from the neural groove, to differentiating the layers of the prefrontal cortex. Thus, although humans are very very different from slime moulds, core aspects of their excitability and social signalling are strongly conserved and remarkably similar.

The fact that people have such similar experiences during quantum change attests to their universality and potentially cosmological status and hence to the validity of psychedelics as a key oracle for discovery of the foundations of consciousness in the mind at large. Realising the symbiotic mind at large solves the hard problem of consciousness and the central enigma of existential cosmology, the nature and purpose of conscious existence, thereby resolving the scientific, eschatological and theistic quests in one “fell swoop”, in a compact, coherent synthesis.

Symbiotic existential cosmology is thus empirically verified in three principal ways:

- (1) Existential cosmology, as an interaction between subjective consciousness and physical reality, is verified through affirmation by empirical experience between conscious human volitional agents, in the same manner that legal transactions, such as sworn evidence, fiduciary duties of care and terms of trust are veridically affirmed. This is necessary for applying Occam's razor to eliminate materialistic cosmologies failing the volitional efficacy test fundamental to human decision-making autonomy and personal responsibility for our actions upon the world.
- (2) The extent of subjective consciousness across the evolutionary tree can be verified through empirical observation of volitional purposiveness in eucaryotes.
- (3) Cosmological symbiosis is verified by statistical evaluation of quantum change experiences of “ultimate reality” in psychedelic and meditational states, as demonstrated in studies by the Johns Hopkins team and others.

Stanislav Groff (1980) notes:

"In one of my early books I suggested that the potential significance of LSD and other psychedelics for psychiatry and psychology was comparable to the value the microscope has for biology or the telescope has for astronomy. My later experience with psychedelics only confirmed this initial impression. These substances function as unspecific amplifiers that increase the cathexis (energetic charge) associated with the deep unconscious contents of the psyche and make them available for conscious processing. This unique property of psychedelics makes it possible to study psychological undercurrents that govern our experiences and behaviours to a depth that cannot be matched by any other method and tool available in modern mainstream psychiatry and psychology. In addition, it offers unique opportunities for healing of emotional and psychosomatic disorders, for positive personality transformation, and consciousness evolution".

I have now taken this to its cosmological conclusion, by taking a Galilean interpretation of Groff's position that also cosmologically inverts the Copernican principle³⁵. That is, I am asserting that subjective consciousness does make human observers, by possession of it, privileged observers of, and participants in the universe, and that a cosmic view of this privileged position is both achievable and facilitated through psychedelics and that this knowledge or "knowing" invokes upon us a primary responsibility to care for and ensure the survival and flowering of sentient life and consciousness within the universe throughout the generations of life.

All the evidence that we have at our disposal indicates that subjective consciousness is manifest in the biota and that only the biota possess it in the fully fledged form we witness it. Notwithstanding the cosmic web, which has fractal similarities to neural tissue (Vazza & Feletti 2020), and the hypothetical idea that some small stars might be conscious (Matloff 2016), the brain appears to be the most complex coherent system in the universe, as the cumulative manifestation of all the forces of nature interacting in consummation of their fractal interaction on all scales, from cosmological symmetry-breaking, running through quarks, protons and neutrons, atomic nuclei, atoms and molecules, to molecular complexes such as the ribosome and membrane, to cell organelles, cells, tissues, organs such as the brain, societies of organisms and the symbiotic biosphere. We know of no other process in the universe, from black holes to stars and the gas clouds of nebulae, or even dark matter, that cumulatively complete the interaction of the fundamental forces in this way.

The evidence also indicates that, while psychedelics create diverse forms of altered conscious states, spanning the entire spectrum, from the paradisiacal to the diabolical, requiring careful guidance, and having significance varying from the sublime to the ridiculous, they constitute humanity's most powerful research avenue to discover what the inner dimensions of conscious experience are, complementing experiences of dreaming and other states, with a central avenue which can be induced and explored, both scientifically and personally by the waking mind. And finally, underlying these diverse visionary phenomena is a deeper enlightenment at the centre of this cyclone, which has the potential to resolve what the existential status of conscious experience is cosmologically, in the experience of moksha, transcending the cycle of birth and death in mystical transformative experiences of long-lasting psychic benefit, whose common features imply they are accessing a common primary conscious condition.

Working to validate entheogenic experiences and conscious states generally requires a different type of verification from physical to establish a phenomenology of the subjective psychedelic state. Peoples experiences of daydreaming and dreaming sleep confirm that very real events can occur, particularly in dreaming. The nature of space and time in dreaming is also undetermined as some people report precognitive dreams (Dunne 1927). We don't usually assess the reality value of internal mental states as the same as everyday experience of the world, but they still often possess features which we recognise and identify as having veridical reality. Likewise some psychedelic states form a diverse population from frank delusions to common claims of profound experiences of a life-changing nature.

Ralph Metzner's (2017) radical empiricism approach gives the foundations of how to assemble such a phenomenology:

"Over 100 years ago the American philosopher William James said that radical empiricism would not dismiss any observations just because we don't have a theory or model to explain them in our current worldview. For that reason, James allowed drug experiences (with nitrous oxide), mystical visions, parapsychological or psi-phenomena and telepathic communications, into science for consideration and further observations. HH the Dalai Lama has formulated a similar epistemology, by his notion of "first person empiricism" – empirical observations made with our own senses. Repeated observations of similar situations by the same observer or similar observers gradually make the observations less "purely subjective" and step-by-step more objective. So the basic formula of radical empiricism is objective = subjective plus one or more. If only one person sees something, it remains purely subjective, like a

³⁵ In physical cosmology, the **Copernican principle** states that humans, on the Earth or in the Solar System, are not privileged observers of the universe. (Wikipedia)

fantasy or a dream. But if at least one other person sees it and can say “yes, I see it” it becomes a little bit more objective, and this can have profoundly healing implications. ... So when people speak about “entities” or “spirits” or “demons” or “visions” or “hallucinations” we want to first separate the observations from the speculations. Then we can gather further observations – which might have been recorded in various books or in works of art, and start the process of making systematic comparisons. ... Our intuitions and subtle inner perceptions can be mistaken just like any outer perceptions – and can and should always be subject to repetition and repeated verification”.

Fig 70: Entheogens are a/the key instrument providing the subjective conscious equivalent to the LHC's role in physical cosmology. Left: Curandero (Luke Brown). Right: Particle shower (Pb ion collision LHC). Just as there are many visions, surrounding one nierika portal to the 'spirit', world, so there have been a multitude of particle showers, for one Higgs particle discovery.

Future generations will come to realise they have been betrayed by Western culture, discovering that:

- (a) A scientific discovery which has features consistent with being the subjective equivalent of the LHC³⁶, a consciousness reactor that could give us access to the core cosmological secrets of the universe, had been suppressed for half a century by the very culture that claims to be the climax of scientific enlightenment.
- (b) That this had happened because this very discovery was perceived by political leaders to be threatening to a consumption-driven society based on venture capital exploitation of the planet's resources for financial gain, combined with adherence to a religious belief which requires the drinking of the saviour's blood and eating His flesh because “without the shedding of blood there is no remission of sin.”
- (c) That this repression, reminiscent of the dark ages, has intentionally acted in such a way as to seek to prevent us from attaining moksha or psychic union with the cosmos, the very ideal that lies at the heart of the spiritual and religious quest for enlightenment and transcendence, because it risks unraveling the status quo.
- (d) That Entheogens giving the respect due could also have critically helped alleviate the planetary crisis that has ensued from human evolutionary emergence as a tribal society, and unfold a symbiotic psychic relationship with reality, just as we are obligately symbiotic with the food and medicinal species on which we depend.
- (e) That instead of helping enable humanity to ensure its survival and the survival of the diversity of life on this planet on which humanity depends, this repression had caused a 50 year delay in addressing a climate and biodiversity crisis, significantly risking the economic welfare, health and survival of these future generations.

This appears to be the situation we are just beginning to emerge from, and yet are still facing today. For the planet to continue to survive over evolutionary and cosmological time scales, climax consciousness is, and has to be, fully sensitive as a complex system to the biosphere. This is necessary to be able manifest a cosmologically conscious response, consistent with perennial survival on evolutionary time scales. The fully evolved consciousness is thus, in its complete form symbiotically biospheric. Its fullest and complete manifestation is biospheric and cannot, in evolutionary terms, be the exclusive provenance of a single dominant species, *Homo sapiens*.

Abstract:

*This article resolves the **central enigma of existential cosmology** – the nature and role of subjective experience – thus providing a direct solution to the "hard problem of consciousness". This solves, in a single coherent cosmological description, the core existential questions surrounding the role of the biota in the universe, the underlying process supporting subjective consciousness and the meaning and purpose of conscious existence. This process has pivotal importance for avoiding humanity causing a mass extinction of biodiversity and possibly our own demise, instead becoming able to fulfil our responsibilities as guardians of the unfolding of sentient consciousness on evolutionary and cosmological time scales.*

The article overviews cultural traditions and current research into psychedelics³⁸ and formulates a panpsychic cosmology, in which the mind at large complements the physical universe, resolving the hard problem of consciousness extended to subjective conscious volition over the universe and the central enigmas of existential cosmology, and eschatology, in a symbiotic cosmological model. The symbiotic cosmology is driven by the fractal non-linearities of the symmetry-broken quantum forces of nature, subsequently turned into a massively parallel quantum computer by biological evolution (Darwin 1859, 1889). Like Darwin's insights, this triple cosmological description is qualitative rather than quantitative, but nevertheless accurate. Proceeding from fractal biocosmology and panpsychic cosmology, through edge of chaos dynamical instability, the excitable cell and then the eucaryote symbiosis create a two-stage process, in which the biota capture a coherent encapsulated form of panpsychism, which is selected for, because it aids survival. This becomes sentient in eucaryotes due to excitable membrane sensitivity to quantum modes and eucaryote adaptive complexity. Founding single-celled eucaryotes already possessed the genetic ingredients of excitable neurodynamics, including G-protein linked receptors and a diverse array of neurotransmitters, as social signalling molecules ensuring survival of the collective organism. The brain conserves these survival modes, so that it becomes an intimately-coupled society of neurons communicating synaptically via the same neurotransmitters, modulating key survival dynamics of the multicellular organism, and forming the most complex, coherent dynamical structures in the physical universe.

This results in consciousness as we know it, shaped by evolution for the genetic survival of the organism. In our brains, this becomes the existential dilemma of ego in a tribally-evolved human society, evoked in core resting state networks, such as the default mode network, also described in the research as "secondary consciousness", in turn precipitating the biodiversity and climate crises. However, because the key neurotransmitters are simple, modified amino acids, the biosphere will inevitably produce molecules modifying the conscious dynamics, exemplified in the biospheric entheogens, in such a way as to decouple the ego and enable existential return to the "primary consciousness" of the mind at large, placing the entheogens as conscious equivalents of the LHC in physics. Thus a biological symbiosis between Homo sapiens and the entheogenic species enables a cosmological symbiosis between the physical universe and the mind at large, resolving the climate and biodiversity crises long term in both a biological and a psychic symbiosis, ensuring planetary survival.

³⁷ This work was conceived out of a quantum change experience evoked by psilocybe mushrooms. Taken together the full dimensions of the work inform a scientific and sacramental paradigm shift towards perennial planetary survival.

³⁸ *psychedelic* "mind-manifesting" psychē (ψυχή, "soul"), dēloun (δηλοῦν, "to make visible, to reveal"), as opposed to *hallucinogenic* – inducing hallucinations and *psychotomimetic* (psycho- mind + mīmētikós, imitative) mimicking psychotic behaviour/personality.

The Decline of Ground-Breaking Disruptive Scientific Discoveries

The research of Park, Leahey & Funk (2022) confirms that papers and patents are becoming less disruptive over time. I want to draw the attention of readers to the fallacy that the past record of science and technology is a basis to believe pure physicalist science will show how the brain “makes” consciousness in any sense greater than the neural correlate of conscious experience. This research needs to be taken seriously and is damning evidence against the assumption that the past progress of mechanistic science will solve the hard problem of conscious volition.

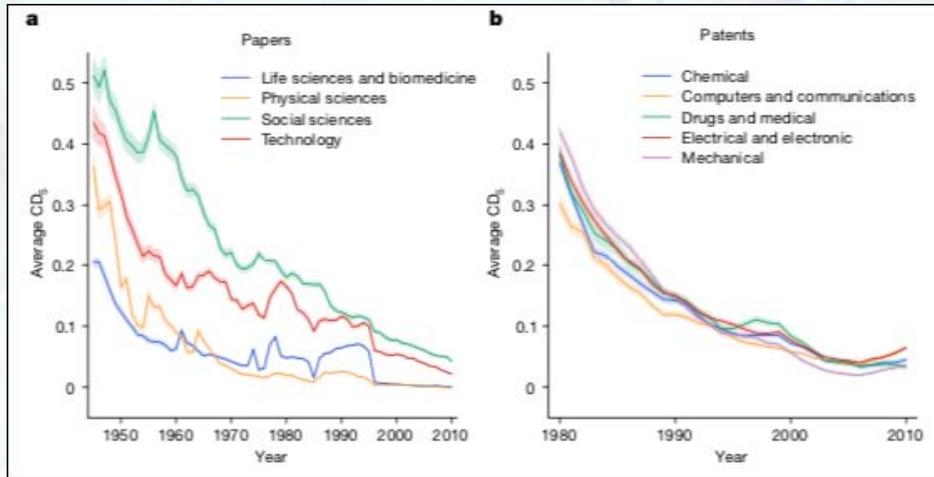

Fig 70b: Decline of disruptive science and technology

The figure shows how devastating the decline has become and indicates the extreme unlikelihood of mechanistic science solving the biggest problem of all. This belief is a product of severe ignorance of the diffuse complexity of the excitation from the prefrontals through to the motor cortex modified by the basal ganglia and the cerebellum, involving both diffuse network activity and deep cyclic connections, which appear to be both uncomputable and empirically undecidable in the quantum universe.

Research Citation Profile

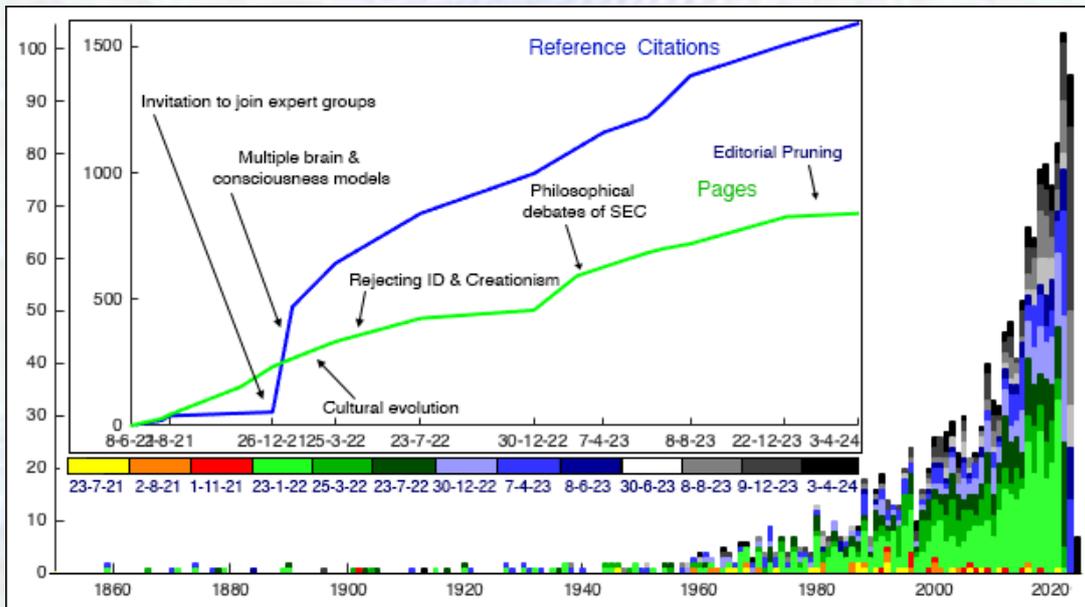

Fig 70c: The research citation profile of Symbolic Existential Cosmology

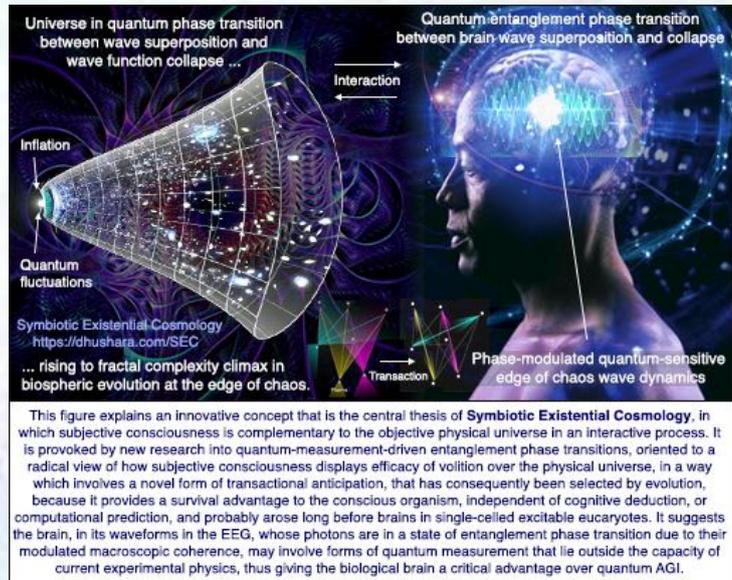

Growth of research and distribution of dates of citations two years since the mushroom trip that precipitated this work, it has accrued 844 pages, with 1593 source references, with a peak of 103 in 2022 and 95 in 2023. Of these 1172 are from 2000 on, 898 from 2010 on and 361 from 2020 on, illustrating the real-time up-to-date nature of the work, which is roughly in four categories, (1) cosmological physics, (2) consciousness and neuroscience, (3) evolutionary biology, (4) metaphysics, animism and religious studies. Fittingly, the oldest citation is Charles Darwin (1859) “On the Origin of the Species”.

The Central Thesis of Symbiotic Existential Cosmology © Chris King 25-10-2023 as part of SEC 1.1.416

The central thesis of Symbiotic Existential Cosmology is that subjective consciousness **interacts with** the physical brain, as a **sub-quantum anticipator** of environmental uncertainty, using space-time – entangled patterns of brain wave states, which are in a **quantum phase transition** between superimposed wave function evolution and measurement-derived wave function collapse, biologically coupled to a complementary **self-critically tuned neurodynamic phase transition**, in which **edge-of-chaos instabilities** in conscious brain dynamics, accompanied by **wave phase-modulation**, implicitly involve both **past and future special-relativistic states** in their entangled wave functions, thus facilitating **efficacy of subjective conscious volition** over the physical universe, by **anticipating existential threats** to organismic survival, a process which is thus **preserved by evolution**, in a universe that is also in a **phase transition** between full entanglement and wave collapse – a process which is itself in a state of **biospheric evolutionary climax at the edge of chaos**.

This resolves two complementary questions essential to a complete existential cosmology:

- The **neurobiological question** of the **hard problem** of the subjectivity of consciousness extended to volition, in which subjective conscious physical volition is manifested through space-time – entangled patterns of brain wave states in a **quantum phase transition**, coupled to self-organised **neurodynamic phase transitions** at the **edge-of-chaos**, complemented by tuned **modulation of wave phase**.
- The **cosmological question** of a universe, in an ongoing partially collapsed **phase transition**, of **quantumness**, between a fully quantum-entangled cosmic wave function and a measurement-reduced universe, substantially quantum-collapsed, due to a plethora of destructive measurement processes that tend to evoke “classical” outcomes, through the projection operator, as in the **cat paradox experiment**, in which planetary biospheres and conscious existence, co-arise in evolutionary climax, at the **edge of chaos**.

Empirical experience confirms that, while the existence of the universe is necessary to our biological survival, subjective conscious experience is primary. We informatively access the physical world, entirely and exclusively through our subjective conscious experiences of it, so subjective consciousness is clearly primary to our knowledge of the physical universe, whose physical quanta in bosons and fermions, we do not experience directly, but only inferentially, through our subjective biologically derived sensory perceptions, along with our inner less-confined subjective experiences in dreams and visionary states. Nevertheless, we understand that, as living organisms, the physical universe in the form of climax planetary biospheres, is necessary to our biological survival, as an inferred foundation of our common existence.

Recall that, in a classical deterministic Laplacian universe, every future state is fully determined by the dynamical laws of evolution and the initial conditions, while in the quantum universe, our knowledge of outcomes is restricted to evolution of the Schrödinger equation, punctuated by collapse of the wave function, resulting in discrete events having a probability determined by the wave function amplitude. This leads to so-called non-local hidden-variable theories, postulated below the quantum level, from pilot waves, through quantum transactions to super-determinism, which seek to explain and determine the specific individual outcomes we see, for example in the Schrödinger **cat paradox experiment**, where a cat subjected to a lethal dose of cyanide, via a radio-active decay is found to be alive or dead but not both, e.g. with a 50-50 probability. The quantum universe is thus in a state of probability-punctuated causality and is neither fully defined, nor causally closed. We attempt to understand this using two classical ideas, (1) the deterministic nature of billiard ball collisions and (2) the probabilities of a classical poker game, applying the first to the Schrödinger evolution and decoherence and the second to the probability interpretation of wave function collapse, but neither are adequate to deal with the non-locality implied by quantum entanglement. God does not play dice!

The central thesis of Symbiotic Existential Cosmology asserts that subjective consciousness is a key process resolving cosmological indeterminacy, by forming a neurodynamic **realisation of these hidden variable interactions** governing non-local entanglement, facilitating biological survival by **anticipating quantum-derived environmental uncertainty** in a manner complementing computational boundary conditions. Space-time anticipation constitutes whole conscious experiences containing a retro-causal echo of the future, both in intuitive conscious anticipation and in rarer more graphic experiences of prescience, precognition and déjà vu. This is not just a deductive process. It cannot be analysed, or predicted by causal computation, for the same reason entanglement prevents transmission of classical information under local Einsteinian causality, and the uncertainties are irreducible, because they involve both computationally intractable environmental uncertainties and indeterminacies due to other live conscious volitional agents.

The central thesis states that the conscious brain uses its continuous wave **tissue potentials** to evoke a unique form of quantum space-time anticipation through global-scale entangled excitations moving in and out of coherence, in a phase transition between full entanglement and wave function collapse, reflected biodynamically in both the phase transition between edge of chaos dynamics at tipping points between chaos and order, and **phase coupling** between continuous electromagnetic wave potentials in the tissues and individual neuronal action potentials in the neural net connectivity. It is thus not just a quantum super-computer, but a sub-quantum conscious anticipator. This results in subjective experience manifesting as a globally omnipresent “stream of consciousness” – **everything, everywhere, all at once** (Gillett 2023), forming an anticipatory “quantum of the present”, utilising memory and the environmental context, but also entangled with the future, in a manner similar to an integral transform, also supported by extensive predictive coding in the brain, acting as a contextual environmental filter, to enable intuitive conscious volitional choices, favouring the survival of the whole organism, by anticipating acute **existential threats**, crises and opportunities and in turn applying subjective conscious volition in our decision-making and behaviour to facilitate our biological survival over evolutionary time scales. By contrast, rational processes are tied more to established classical causal factors compatible with cerebral cognition. The subjective interaction can thus move seamlessly from uncertainty-dominant anticipative intuition, to a context-dominant predictively cognitive response. Because brain dynamics do not involve independent identically-distributed **IID measurements**, as their contexts are continually changing, there is no evidence that they converge to the classical. Nor can it be established that the quantum universe, or brain, is causally closed to subjectivity.

This overall picture coincides with our empirical subjective experience of conscious intuitive decision-making, resulting in veridical perception of our volitional action in intentional behaviour. For this purpose, SEC asserts that there are two scientific empirical avenues, (a) **verified objective observation** and (b) **affirmed subjective experience**, consistent with the etymology and current meaning of “empirical” as “based on, concerned with, or verifiable by observation, or experience, rather than theory or pure logic” (Oxford Languages). Given the fact that the overwhelming opinion of sane people is that we have conscious empirical intentional ability to affect our fates and this is the basis of criminal and corporate law on intent, this has a very high level of empirical validation, which even scientific physicalists, in all honesty, need to concede is the case. Indeed SEC is the only type of cosmology that respects our empirical experience without invoking some form of illusionism that our subjective experience of active agency is a fallacious deception.

Symbiotic Existential Cosmology asserts that subjective conscious intuition in decision-making and volition can influence the ongoing brain state, in situations where there is quantum-derived environmental uncertainty, as is critical for our survival, and that the brain state accompanying subjective conscious volition over the physical universe, occurs only when the physical brain dynamic is in a self-organised critical state of physical phase transition at the edge of chaos, between a more chaotic and a more ordered regime, which is itself at a quantum uncertain unstable tipping point. This avoids causal conflict between subjective volition and a determined ongoing physical brain state. It is achieved by minimising quantum measurement in favour of a higher degree of anticipatory phase entanglement than the surrounding universe, consistent with minimal collapse to the classical. The efficacy of conscious anticipation in survival in the wild is essential to explain why subjective conscious volition has an evolutionary advantage, over non-conscious computational processing and has thus been conserved by evolution, giving conscious biological brains a critical advantage over AI, using phase transitional entanglement that is not accessible to objective physical interrogation.

While SEC is agnostic to specific quantum interpretations, it finds the approach of **transactional** super-causality helpful as an explanation of quantum anticipation, through a trans-causal future-past handshaking phase transition, from a plasma-like interaction of contingent offer and confirmation waves, to a solid-like set of real interactions between emitters and absorbers, which, like subjective experience, stands outside physical space-time.

Furthermore, this is achieved because the brain also uses **phase modulation** of its waveforms, evidenced in electro- and magneto-encephalograms, through hand-shaking phase coupling of individual action potentials with the continuous tissue potentials. Because brain waves in the EEG share the features of macroscopic radio waves, they share features of entanglement of their fields that we witness in coherent laser light as well. The modulated phase coherence of global brain dynamics in dynamic feedback with more decentralised partially decoherent local processing, invokes the “spotlight” of coherent conscious attention, with a sub-conscious periphery, common to theories such as **global neuronal workspace** theory. Symbiotic Existential Cosmology asserts that these phase modulations are not just analogous to the foundation concept of quantum uncertainty through **wave beats**, but constitute a unique form of quantum measurement by the brain of its own internal dynamical states, distinct from using the Born probability interpretation by destructive measurement, as in standard experimental physics, such as the cat paradox experiment, while keeping destructive measurement minimal to facilitate quantum anticipation.

In turn, this enables the subjectively conscious brain to collapse the probability multiverse of future quantum uncertainties, to unfold the line of emerging world history that we invoke together, for better or worse, through our choices in the uncertain “karmic” quantum environment, as live autonomous intentional agents, inheriting personal conscious responsibility for our actions, particularly in relation to the biosphere and it’s and our survival as a species.

The Cosmological Axiom of Primal Subjectivity

To begin the physics and neuroscience section, I shall put the core axiom into precise formulation, taking into account that the existence of primary subjectivity is an **undecidable proposition**, from the **physical point of view**, in the sense of Gödel, but is **empirically certain** from the **experiential point of view**, we come to the following:

- (1) We start on home ground, i.e. with human conscious volition, where we can clearly confirm both aspects of reality – **subjectively experiential** and **objectively physical**.
- (2) We then affirm, as empirical experience, that we have **efficacy of subjective conscious volition over the physical universe**, manifest in every intentional act we make, as is necessary for our behavioural survival – as evidenced by my consciously typing this passage into physical form, and that this is in manifest conflict with pure physicalism asserting the contrary.
- (3) We now apply **Occam's razor**, not just on parsimony, but **categorical inability of pure materialism**, using only **physical processes**, which **can only be empirically observed**, to deal with **subjective consciousness**, because this **can only be empirically experienced** and is private to observation. Classical neuroscience accepts consciousness only as an **epiphenomenon** – an internal model of reality constructed by the brain, but **denies volition**, as a delusion perpetrated by evolution to evoke the spectre of intentional behaviour. This leads to intractability of the **hard problem of consciousness**, extended to the physicalist blanket denial of conscious physical volition, which we perceive veridically in our conscious perception of our enacted intent, this becomes the **extended hard problem**.
- (4) We then scrutinise the physical aspect and realise we **cannot empirically confirm classical causal closure the universe in brain dynamics** because: (a) the **dynamics is fractal to the quantum-molecular level**, (b) **non-IID** processes don't necessarily converge to the classical and (c) **experimental verification is impossible** because we would need essentially to trace the neurodynamics of every neuron, when the relevant dynamics is at the unstable edge of chaos and so is quantum sensitive. This remains experimentally and technologically unfeasible. Neither can we prove consciousness causes brain states leading to volition, because consciousness can only be experienced and not observed, so this is a genuine undecidable proposition physically.
- (5) This sets up the status of: **“Does subjective conscious volition have efficacy over the universe?”** to be an **empirically undecidable cosmological proposition** from the **physical perspective**, in the sense of Gödel. From the **experiential perspective** however, it is an **empirical certainty**.
- (6) We therefore add a single minimal **cosmological axiom**, to state the affirmative proposition – **“Subjective conscious volition has efficacy over the physical universe”**. We also need to bear in mind that a physicalist could make the counter proposition that it doesn't, and both could in principle be explored, like the continuum hypothesis in mathematics – that there is no infinite cardinality between those of the countable rationals and uncountable reals.
- (7) **Rescaling the primal axiom**: We now need to scale this axiom **all the way down to the quantum level**, because it is a **cosmological axiom** that means that **the universe has some form of primal subjective volition**, so we need to investigate its possible forms. The only way we can do this, as we do with one another about human consciousness, where we can't directly experience one another's consciousness, is to make deductions from the physical effects of volition – in humans, organisms, amoeba-flagellates, prokaryotes, biogenesis, butterfly effect systems and quanta.
- (8) **Quantum experience and volition**: We immediately realise that quantum reality has **two complementary processes, consciousness and volition**:
 - (a) **Quantum consciousness**: The wild wave function which contains both past and future implicit “information” under special relativity, corresponding to the **quantum-experiential interface of primal subjectivity**.
 - (b) **Quantum volition**: Collapse of the wave function, which violates causality and in which the normalised wave power space leaves the quantum total free will where to be measured, which is the **quantum-volitional interface of primal subjectivity**.
- (9) **Primal cosmological subjectivity**: This means that subjectivity is a primal complement to the quantum universe and that the cosmos as a whole in an interactive process between physical objectivity and experiential subjectivity, arising at the cosmic origin.
- (10) **Two potentially valid cosmologies arise from the physical perspective, but only one from the experiential perspective**:

As with any undecidable proposition, from the objective perspective, pure physicalists can, on the one hand, continue to contend that the quantum has no consciousness or free will and that uncertainty is “random” and cite lack of an obvious bias violating the Born interpretation, and develop that approach, thus claiming volition is a self-fulfilling delusion of our internal model of reality. But Symbiotic Existential Cosmology can validly argue that uncertainty could be due to a complex quasi-random process, e.g. a special relativistic transactional collapse process, which by default, the quantum, by virtue of its wave function context does have “conscious” free will over, allowing us and the diversity of life to also be subjectively conscious and affect the world around us, unlike the pure materialist model.
- (11) Symbiotic Existential Cosmology, thus shows that CA, in the form of subjective conscious volition, is **undecidable physically**, although it is **certain experientially** and **necessary for subjective conscious survival**.

1 The Cosmological Problem of Consciousness

The human **existential condition** consists of a complementary paradox. To survive in the world at large, we have to accept the external reality of the physical universe, but we gain our entire knowledge of the very existence of the physical universe through our **conscious** experiences, which are **entirely subjective** and are complemented by other experiences in dreams and visions which also sometimes have the genuine reality value we describe as **veridical**. The universe is thus in a fundamental sense a description of our consensual subjective experiences of it, experienced from birth to death, entirely and only through the relentless unfolding spectre of subjective consciousness.

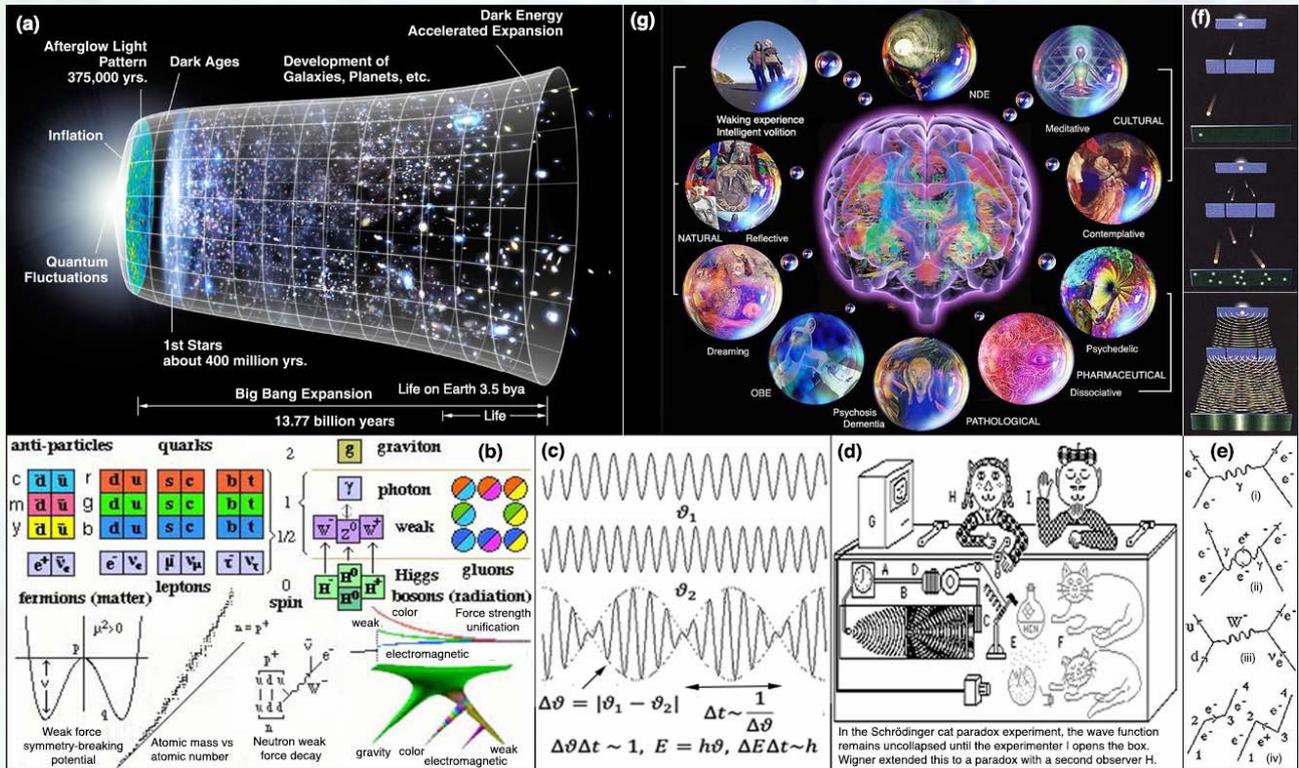

Fig 71: (a) Cosmic evolution of the universe (WMAP King 2020b). Life has existed on Earth for a third of the universe’s 13.7 b ya lifetime. (b) Symmetry-breaking of a unified superforce into the four wave-particle forces of nature, colour, weak, electromagnetic and gravity with the first three forming the standard model and with the weak-field limit of general relativity (Wilczek 2015) comprising the **core model**. (c) quantum uncertainty defined through wave coherence beats, (d) Schrödinger cat experiment. Schrödinger famously said “*The total number of minds in the universe is one*”, preconceiving Huxley’s notion of the mind at large used as this monograph’s basis for cosmological symbiosis. Quantum theory says the cat is in both live and dead states with probability 1/2 but the observer finds the cat alive or dead, suggesting the conscious observer collapses the superimposed wave function. (e) Feynman diagrams in special relativistic quantum field theories involve both retarded (usual) and advanced (time backwards) solutions because the Lorenz energy transformations ensuring the atom bomb works have positive and negative energy solutions $E = \pm \sqrt{p^2 + m^2}$. Thus electron scattering (iv) is the same as positron creation-annihilation³⁹. Each successive order

Feynman diagram has a contribution reduced by a factor $\alpha = \frac{e^2}{2\pi\epsilon_0\hbar c} \sim \frac{1}{137}$, the fine structure constant. (f) Double slit

interference shows a photon emitted as a particle passes through both slits as a wave before being absorbed on the photographic plate as a particle. The trajectory for an individual particle is quantum uncertain but the statistical distribution confirms the particles have passed through the slits as waves. (g) Cosmology of conscious mental states (King 2021a). Kitten’s Cradle a love song.

³⁹ Feynman notes in his Nobel address: “I received a telephone call one day at the graduate college at Princeton from Professor Wheeler, in which he said, ‘Feynman, I know why all electrons have the same charge and the same mass’ ‘Why?’ ‘Because, they are all the same electron!’” “suppose that the world lines which we were ordinarily considering before in time and space – instead of only going up in time were a tremendous knot, and then, when we cut through the knot, by the plane corresponding to a fixed time, we would see many, many world lines and that would represent many electrons, except for one thing. If in one section this is an ordinary electron world line, in the section in which it reversed itself and is coming back from the future we have the wrong sign to the proper time – to the proper four velocities – and that’s equivalent to changing the sign of the charge, and, therefore, that part of a path would act like a positron.” “But, Professor”, I said, “there aren’t as many positrons as electrons.” This became the basis of his representation of positrons as electron holes and for the entire Feynman diagram approach to quantum field theories.

The Physical Viewpoint

The religious anthropocentric view of the universe was overthrown, when Copernicus, in 1543 deduced that the Earth instead of being in the centre of the cosmos instead, along with the other solar system planets, rotated in orbits around the Sun. Galileo defended heliocentrism based on his astronomical observations of 1609. By 1615, Galileo's writings on heliocentrism had been submitted to the Roman Inquisition which concluded that heliocentrism was foolish, absurd, and heretical since it contradicted Holy Scripture. He was tried by the Inquisition, found "vehemently suspect of heresy", and forced to recant. He spent the rest of his life under house arrest.

The Copernican revolution in turn resulted in the rise of classical materialism defined by Isaac Newton's laws of motion (1642 – 1726), after watching the apple fall under gravity, despite Newton himself being a devout Arian Christian who used scripture to predict the apocalypse. The classically causal Newtonian world view, and Pierre Simon Laplace's (1749 – 1827) view of mathematical determinism "that if the current state of the world were known with precision, it could be computed for any time in the future or the past", came to define the universe as a classical mechanism in the ensuing waves of scientific discovery in classical physics, chemistry and molecular biology, climaxing with the decoding of the human genome, validating the much more ancient atomic theory of Democritus (c. 460 – c. 370 BC). The classically causal universe of Newton and Laplace has since been fundamentally compromised by the discovery of quantum uncertainty and its "spooky" features of quantum entanglement.

In counterposition to materialism, George Berkeley (1685 – 1753) is famous for his philosophical position of "immaterialism", which denies the existence of material substance and instead contends that familiar objects like tables and chairs are ideas perceived by our minds and, as a result, cannot exist without being perceived. Berkeley argued against Isaac Newton's doctrine of absolute space, time and motion in a precursor to the views of Mach and Einstein. Interest in Berkeley's work increased after 1945 because he had tackled many of the issues of paramount interest to 20th century philosophy, such as perception and language.

The core reason for the incredible technological success of science is not the assumption of macroscopic causality, but the fact that the quantum particles come in two kinds. The integral spin particles, called bosons, such as photons, can all cohere together, as in a laser and thus make forces and radiation, but the half-integer spin particles, called fermions, such as protons and electrons, which can only congregate in pairs of complementary spin, are incompressible and thus form matter, inducing a universal fractal complexity, via the non-linearity of the electromagnetic and other quantum forces. The fermionic quantum structures are small, discrete and divisible, so the material world can be analysed in great detail. Given the quantum universe and the fact that brain processes are highly uncertain, given changing contexts and unstable tipping points at the edge of chaos, objective science has no evidential basis to claim the brain is causally closed and thus falsely conclude that we therefore have no agency to apply our subjective and consciousness to affect the physical world around us. By agency here I mean full subjective conscious volition, not just objective causal functionality (Brizio & Tirassa 2016, Moreno & Mossio 2015), or even autopoiesis (Maturana & Varela 1972).

The nature of conscious experience remains the most challenging enigma in the scientific description of reality, to the extent that we not only do not have a credible theory of how this comes about but we don't even have an idea of what shape or form such a theory might take. While physical cosmology is an objective quest, leading to theories of grand unification, in which symmetry-breaking of a common super-force led to the four forces of nature in a big-bang origin of the universe, accompanied by an inflationary beginning, the nature of conscious experience is entirely subjective, so the foundations of objective replication do not apply. Yet for every person alive today, subjective conscious experiences constitute the totality of all our experience of reality, and physical reality of the world around us is established through subjective consciousness, as a consensual experience of conscious participants.

Erwin Schrödinger: *Consciousness cannot be accounted for in physical terms. For consciousness is absolutely fundamental.*

Arthur Eddington: *The stuff of the world is mind stuff.*

J. B. S. Haldane: *We do not find obvious evidence of life or mind in so-called inert matter...; but if the scientific point of view is correct, we shall ultimately find them, at least in rudimentary form, all through the universe.*

Julian Huxley: *Mind or something of the nature as mind must exist throughout the entire universe. This is, I believe, the truth.*

Freeman Dyson: *Mind is already inherent in every electron, and the processes of human consciousness differ only in degree and not in kind from the processes of choice between quantum states which we call "chance" when they are made by electrons.*

David Bohm: *It is implied that, in some sense, a rudimentary consciousness is present even at the level of particle physics.*

Max Planck: *"I regard consciousness as fundamental. I regard matter as derivative from consciousness. We cannot get behind consciousness."*

Werner Heisenberg: *Is it utterly absurd to seek behind the ordering structures of this world a "consciousness" whose "intentions" were these very structures?*

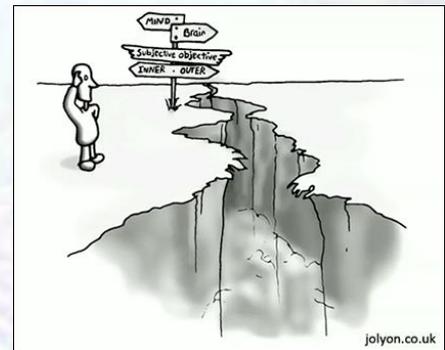

Andrei Linde: *Will it not turn out, with the further development of science, that the study of the universe and the study of consciousness will be inseparably linked, and that ultimate progress in the one will be impossible without progress in the other?*

The **hard problem** of consciousness (Chalmers 1995) is the problem of explaining why and how we have phenomenal first-person subjective experiences sometimes called "qualia" that feel "like something", and more than this, evoke the entire panoply of all our experiences of the world around us. Chalmers comments (201) *"Why should physical processing give rise to a rich inner life at all? It seems objectively unreasonable that it should, and yet it does."*

By comparison, we assume there are no such experiences for inanimate things such as a computer, or a sophisticated form of artificial intelligence. Two extensions of the hard problem are the **hard problem extended to volition** and the **hard manifestation problem** how is experience manifested in waking perception, dreams and entheogenic visions?

Fig 71b: The hard problem's explanatory gap – an uncrossable abyss.

Although there have been significant strides in both electrodynamic (EEG and MEG), chemodynamic (fMRI) and connectome imaging of active conscious brain states, we still have no idea of how such collective brain states evoke the subjective experience of consciousness to form the internal model of reality we call the conscious mind, or for that matter volitional will. In Jerry Fodor's words: *"Nobody has the slightest idea how anything material could be conscious. Nobody even knows what it would be like to have the slightest idea about how anything material could be conscious."*

Nevertheless, opinions about the hard problem and whether consciousness has any role in either perception or decision-making remain controversial and unresolved. The hard problem is contrasted with easy, functionally definable problems, such as explaining how the brain integrates information, categorises and discriminates environmental stimuli, or focuses attention. Subjective experience does not seem to fit this explanatory model. Reductionist materialists, who are common in the brain sciences, particularly in the light of the purely computational world views induced by artificial intelligence, see consciousness and the hard problem as issues to be eliminated by solving the easy problems. Daniel Dennett (2005) for example argues that, on reflection, consciousness is functionally definable and hence can be corralled into the objective description. Arguments against the reductionist position often cite that there is an explanatory gap (Levine 1983) between the physical and the phenomenal. This is also linked to the conceivability argument, whether one can conceive of a micro-physical "zombie" version of a human that is identical except that it lacks conscious experiences. This, according to most philosophers (Howell & Alter 2009), indicates that physicalism, which holds that consciousness is itself a physical phenomenon with solely physical properties, is false.

David Chalmers (1995), speaking in terms of the hard problem, comments: *"The only form of interactionist dualism that has seemed even remotely tenable in the contemporary picture is one that exploits certain properties of quantum mechanics."* He then goes on to cite (a) John Eccles' (1986) citing of consciousness providing the extra information required to deal with quantum uncertainty thus not interrupting causally deterministic processes, if they occur, in brain processing and (b) the possible involvement of consciousness in "collapse of the wave function" in quantum measurement. We next discuss both of these loopholes in the causal deterministic description.

Two threads in our cosmological description indicate how the complementary subjective and objective perspectives on reality might be unified. Firstly, the measurement problem in the quantum universe, appears to involve interaction with a conscious observer. While the quantum description involves an overlapping superposition of wave functions, the **Schrödinger cat paradox**, fig 71(d), shows that when we submit a cat in a box to a quantum measurement, leading to a 50% probability of a particle detection smashing a flask of cyanide, killing the cat, when the conscious observer opens the box, they do not find a superposition of live and dead cats, but one cat, either stone dead or very alive. This leads to the idea that subjective consciousness plays a critical role in collapsing the superimposed wave functions into

a single component, as noted by John von Neumann, who stated that collapse could occur at any point between the precipitating quantum event and the conscious observer, and others likewise (Greenstein 1988, Stapp 1995, 2007).

Wigner & Margenau (1967) used a variant of the cat paradox to argue for conscious involvement. In this version, we have a box containing a conscious friend who reports the result later, leading to a paradox about when the collapse occurs – i.e. when the friend observes it or when Wigner does. Wigner discounted the observer being in a superposition themselves as this would be preceded by being in a state of effective “suspended animation”. As this paradox does not occur if the friend is a non-conscious mechanistic computer, it suggests consciousness is pivotal. Henry Stapp (2009) in “Mind, Matter and Quantum Mechanics” has an overview of the more standard theories.

While systems as large as 2000 atoms (Fein et al. 2019) that of gramicidin A1, a linear antibiotic polypeptide composed of 15 amino acids (Shayeghi et al. 2020), and even a deep-frozen tardigrade (Lee et al. 2021) have been found in a superposition of states resulting in interference fringes, indicating that the human body or brain could be represented as a quantum superposition, it is unclear that subjective experience can. More recent experiments involving two interconnected Wigners’ friend laboratories also suggest the quantum description “cannot consistently describe the use of itself” (Frauchiger & Renner 2018). An experimental realisation (Bong et al. 2020) implies that there is no such thing as objective reality, as quantum mechanics allows two observers to experience different, conflicting realities. These paradoxes underly the veridical fact that conscious observers make and experience a single course of history, while the physical universe of quantum mechanics is a multiverse of probability worlds, as in Everett’s many worlds description, if collapse does not occur. This postulates split observers, each unaware of the existence of the other, but what kind of universe they are then looking at seems inexorably split into multiverses, which we do not experience.

In this context Barrett (1999) presents a variety of possible solutions involving many worlds and many minds, or one mind and in the words of Saunders (2001) in review has resonance with existential cosmology:

Barrett’s tentatively favoured solution [is] the one also developed by Squires (1990). It is a one-world dualistic theory, with the usual double-standard of all the mentalistic approaches: whilst the physics is precisely described in mathematical terms, although it concerns nothing that we ever actually observe, the mental – in the Squires-Barrett case a single collective mentality – is imprecisely described in non-mathematical terms, despite the fact that it contains everything under empirical control.

In **quantum entanglement**, two or more particles can be prepared within the same wave function. For example, in a laser, an existing wave function can capture more and more photons in phase with a standing wave between two mirrors by stimulated emission from the excited medium. In other experiments pairs of particles can be generated inside a single wave function. For example an excited Calcium atom with two outer electrons can emit a blue and a yellow photon with complementary polarisations in a spin-0 to spin-0 transition, as shown in fig 72(8). In this situation when we sample the polarisation of one photon, the other instantaneously has the complementary polarisation even when the two detections take place, without there being time for any information to pass between the detectors at the speed of light. John Bell (1964) proved that the results predicted by standard quantum mechanics when the two detectors were set at varying angles violated the constraints defined by local Einsteinian causality, implying quantum non-locality, decried by Einstein, Rosen and Podolsky (1935) as an incomplete view:

In a complete theory there is an element corresponding to each element of reality. A sufficient condition for the reality of a physical quantity is the possibility of predicting it with certainty, without disturbing the system. In quantum mechanics in the case of two physical quantities described by non-commuting operators, the knowledge of one precludes the knowledge of the other. Then either (1) that the description of reality as given by a wave function in quantum mechanics is not complete, or (2) these two quantities cannot have simultaneous reality. Consideration of the problem of making predictions concerning a system on the basis of measurements made on another system that had previously interacted with it leads to the result that if (1) is false then (2) is also false. One is thus led to conclude one precludes the knowledge of the other. Then either (1) that the description of reality as given by a wave function is not complete.

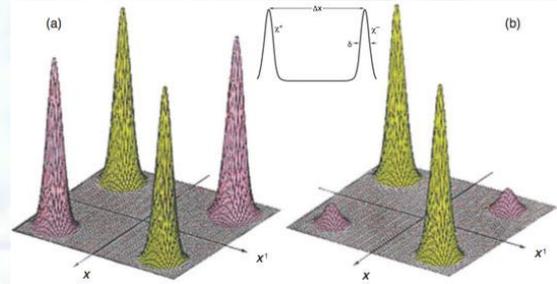

The experimental verification was confirmed by Alain Aspect and others (1982) over space-like intervals using rapidly time varying analysers (fig 72(8)), receiving a Nobel in 2022. There are other more complex forms of entanglement such as the W and GHZ states (Greenberger, Horne & Zeilinger 1989, Mermin 1990), used in quantum computing (Coecke et al. 2021), types of entangled state that involve at least three subsystems (particle states, or qubits). Extremely non-classical properties of the GWZ state have been observed.

Albert Einstein dubbed the phenomenon “spooky action at a distance” and proposed that the effect actually came about because the particles contained hidden variables, or instructions, which had already predetermined their

states. This doesn't mean that quantum mechanics is incomplete, superficial or wrong, but that a hidden variable theory we do not have direct access to within uncertainty may provide the complete description.

Other notions of collapse (see King [2020b](#) for details) involve interaction with third-party quanta and the world on classical scales. **Decoherence** is commonly attributed to entanglement with third party particles and all forms of quantum entanglement (Aspect et al. 1982), or its broader phase generalisation, **quantum discord** (Ollivier & Zurek 2002) involve decoherence (Zurek 1991, 2003) with respect to other particles, because the system of interest has become coupled to other wave-particles. But these can generate further entanglements, not wave function collapse. **Recoherence** (Bouchard et al. 2015) can reverse decoherence, consistent with quantum erasure, supporting the notion that all non-conscious physical structures can exist in superpositions. Another notion is **quantum darwinism** (Zurek 2009), in which some states survive because they are especially robust in the face of decoherence.

Fig 71c: Cancellation of off-diagonal entangled components in decoherence by damping, modelling extraneous collisions (Zurek 2003).

Penrose's objective-collapse theory, postulates the existence of an objective threshold governing the collapse of quantum-states, related to the difference of the spacetime curvature of these states in the universe's fine-scale structure. He suggested that at the Planck scale, curved spacetime is not continuous, but discrete and that each separated quantum superposition has its own piece of spacetime curvature, a blister in spacetime. Penrose suggests that gravity exerts a force on these spacetime blisters, which become unstable above the Planck scale and collapse to just one of the possible states. Atomic-level superpositions would require 10 million years to reach OR threshold, while an isolated 1 kilogram object would reach OR threshold in 10^{-37} s. Objects somewhere between these two scales could collapse on a timescale relevant to neural processing. An essential feature of Penrose's theory is that the choice of states when objective reduction occurs is selected neither randomly nor algorithmically. Rather, states are selected by a "non-computable" influence embedded in the Planck scale of spacetime geometry, which in "The Emperor's New Mind" (Penrose 1989) he associated with conscious human reasoning.

Spontaneous random collapse models GRW (Ghirardi, Rimini, & Weber 1986) include an extra factor complementing the Schrödinger equation forcing random collapse over a finite time. Both Penrose's gravitationally induced collapse and the variants of GRW theories such as continuous spontaneous localisation (CSL) involving gradual, continuous collapse rather than a sudden jump have recently been partially eliminated by experiments derived from neutrino research which have failed to detect the very faint x-ray signals the local jitter of physical collapse models imply.

Then we have **pilot waves**⁴⁰ (Bohm 1952), which identify particles as having real positions, thus not requiring wave function collapse, but have problems with handling creation of new particles. Images of such trajectories can be seen in weak quantum measurement and surreal Bohmian trajectories in [fig 57](#). However, the pilot wave theory has a fundamental problem with particle creation because stipulating a position for the particle doesn't work if a high energy photon then undergoes a creation event and then splits into an electron and a positron, where we have a potentially infinite number of possible trajectories of the ensuing particles. Attempts to solve this (Duerr et al. 2004, 2005, Nikolic, H 2010) involve two problems (1) the configuration space splits into a potentially infinite number of configurations and (2) A stochastic process is arbitrarily introduced for creation.

In the approach of SED (de la Peña et al. 2020), the stochastic aspect corresponds to the effects of the collapse process into the classical limit, but here consciousness has been represented by the zero point field (ZPF) (Keppler 2018).

David Albert (1992), in "Quantum Mechanics and Experience", cites objections to virtually all descriptions of collapse of the wave function. In terms of von Neumann's original definition, which allowed for collapse to take place any point

⁴⁰David Bohm's (1952) pilot wave theory posits a real position and momentum for a particle such as a photon guided by a particular non-local form of pilot wave. It illustrates a form of hidden variable theory which does not require collapse of the wave function, but the predictions hold only for a situation where no new particles are created with new degrees of freedom during the trajectory. Its interpretation is thus inconsistent with the Feynman approach, where the transition probability includes all paths and all possible virtual particles created and annihilated during the transition. To the extent that its predictions coincide with those of quantum mechanics, phenomena, from weak quantum measurement (Kocsis et al. 2011) to surreal Bohmian trajectories (Mahler et al. 2016) can also be interpreted correctly by entanglement using standard quantum mechanics.

from the initial event to the conscious observation of it, what he concluded was that there must be two fundamental laws about how the states of quantum-mechanical systems evolve:

Without measurements all physical systems invariably evolve in accordance with the dynamical equations of motion, but when there are measurements going on, the states of the measured systems evolve in accordance with the postulate of collapse. What these laws actually amount to will depend on the precise meaning of the word measurement. And it happens that the word measurement simply doesn't have any absolutely precise meaning in ordinary language; and it happens (moreover) that von Neumann didn't make any attempt to cook up a meaning for it, either.

However, if collapse always occurs at the last possible moment, as in Wigner's (1961) view, things get complicated:

All physical objects almost always evolve in strict accordance with the dynamical equations of motion. But every now and then, in the course of some such dynamical evolutions, the brain of a sentient being may enter a state wherein states connected with various different conscious experiences are superposed; and at such moments, the mind connected with that brain opens its inner eye, and gazes on that brain, and that causes the entire system (brain, measuring instrument, measured system, everything) to collapse, with the usual quantum-mechanical probabilities, onto one or another of those states; and then the eye closes, and everything proceeds again in accordance with the dynamical equations of motion.

We thus end up with either purely physical systems, which evolve in accordance with the dynamical equations of motion or conscious systems which do contain sentient observers. These systems evolve in accordance with the more complicated rules described above. ... So in order to know precisely how things physically behave, we need to know precisely what is conscious and what isn't. What this "theory" predicts will hinge on the precise meaning of the word conscious; and that word simply doesn't have any absolutely precise meaning in ordinary language; and Wigner didn't make any attempt to make up a meaning for it; and so all this doesn't end up amounting to a genuine physical theory either.

But he also discounts related theories relating to macroscopic processes:

All physical objects almost always evolve in strict accordance with the dynamical equations of motion. But every now and then, in the course of some such dynamical evolutions (in the course of measurements, for example), it comes to pass that two macroscopically different conditions of a certain system (two different orientations of a pointer, say) get superposed, and at that point, as a matter of fundamental physical law, the state of the entire system collapses, with the usual quantum-mechanical probabilities, onto one or another of those macroscopically different states. But then we again have two sorts of systems microscopic and macroscopic and again we don't precisely know what macroscopic is.

He even goes to the trouble of showing that no obvious empirical test can distinguish between such variations, including decoherence e.g. from air molecules, and with the GRW theory above, where other problems arise about the nature and consequences of collapse on future evolution.

Tipler (2012, 2014), using quantum operators, shows that, in the many worlds interpretation, quantum non-locality ceases to exist because the first measurement of an entangled pair, e.g. spin up or down, splits the multiverse into two deterministic branches, in each of which the state of the second particle is determined to be complementary in each multiverse branch, so no nonlocal "spooky action a distance" needs, or can take place.

This also leads to a fully-deterministic multiverse:

Like the electrons, and like the measuring apparatus, we are also split when we read the result of the measurement, and once again our own split follows the initial electron entanglement. Thus quantum nonlocality does not exist. It is only an illusion caused by a refusal to apply quantum mechanics to the macroworld, in particular to ourselves.

Many-Worlds quantum mechanics, like classical mechanics is completely deterministic. So the observers have only the illusion of being free to chose the direction of spin measurement. However, we know my experience that there are universes of the multiverse in which the spins are measured in the orthogonal directions, and indeed universes in which the pair of directions are at angles ϑ at many values between 0 and $\pi/2$ radians. To obtain the Bell Theorem quantum prediction in this more general case, where there will be a certain fraction with spin in one direction, and the remaining fraction in the other, requires using Everett's assumption that the square of the modulus of the wave function measures the density of universes in the multiverse.

There is a fundamental problem with Tipler's explanation. The observer is split into one that observes the cat alive and the other observes it dead. So everything is split. Nelson did and didn't win the battle of Copenhagen by turning his blind eye, so Nelson is also both a live and dead Schrödinger cat. The same for every idiosyncratic conscious decision we make, so history never gets made. Free will ceases to exist and quantum measurement does not collapse the wave function. So we have a multiverse of multiverses with no history at all. Hence no future either.

This simply isn't in any way how the real universe manifests. The cat IS alive or dead. The universe is superficially classical because so many wave functions have collapsed or are about to collapse that the quantum universe is in a dynamical state of creating superpositions and collapsing nearly all of them, as the course of history gets made. This edge of chaos dynamic between collapse and wave superposition allows free will to exist within the cubic centimetre of quantum uncertainty. We are alive. Subjective conscious experience is alive and history is being unfolded as I type.

Nevertheless the implications of the argument are quite profound in that both a fully quantum multiverse and a classical universe are causally deterministic systems, showing that the capacity of subjectively conscious free-will to throw a spanner in the works comes from the interface we experience between these two deterministic extremes.

Transactional Interpretations: Another key interpretation, which extends the Feynman description, to real particle exchanges, is the **transactional interpretation** TI (Cramer 1986, King 1989, Kastner 2012, Cramer & Mead 2020) where real quanta are also described as a hand-shaking between retarded (usual time direction) and advanced (retrocausal) waves from the absorber, called "offer" and "confirmation" waves. TI arose from the Wheeler-Feynman (WF) time-symmetric theory of classical electrodynamics (Wheeler and Feynman 1945, 1949, Feynman 1965), which proposed that radiation is a time-symmetric process, in which a charge emits a field in the form of half-retarded, half-advanced solutions to the wave equation, and the response of absorbers combines with that primary field to create a radiative process that transfers energy from an emitter to an absorber.

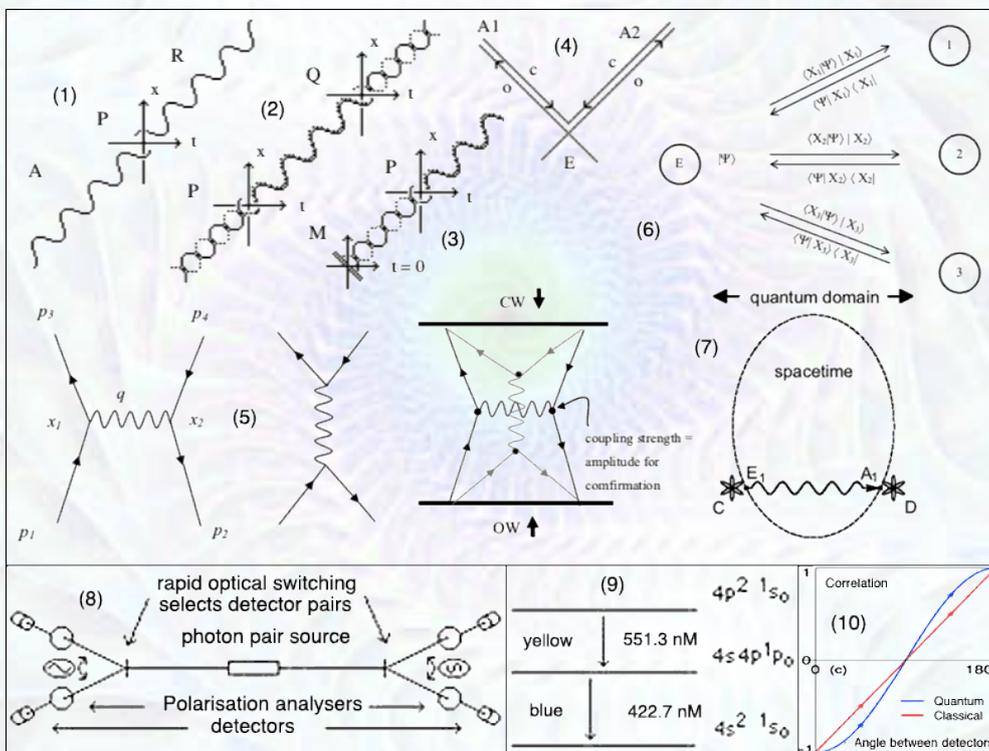

Fig 72: (1) In TI a transaction is established by crossed phase advanced and retarded waves. (2) The superposition of these between the emitter and absorber results in a real quantum exchanged between emitter P and future absorber Q. (3) The origin of the positive energy arrow of time envisaged as a phase reflecting boundary at the cosmic origin (Cramer 1983). (4) Pair splitting entanglement can be explained by transactional handshaking at the common emitter. (5) The treatment of the quantum field in PTI is explained by assigning a different status to the internal virtual particle transactions (Kastner 2012). (6) A real energy emission in which time has broken symmetry involves multiple transactions between the emitter and many potential absorbers with collapse modelled as a symmetry breaking, in which the physical weight functions as the probability of that particular process as it 'competes' with other possible processes (Kastner 2014). (7) Space time emerging from a transaction (Kastner 2021a). (8) Entanglement experiment with time varying analysers (Aspect et al. 1982). A calcium atom emits two entangled photons with complementary polarisation each of which travels to one of two detectors oscillating so rapidly there is no time to send information at the speed of light between the two detector pairs. (9) The blue and yellow photon transitions. (10) The quantum correlations blue exceed Bell's limits of communication between the two at the speed of light. The experiment is referred to as EPR after Einstein, Podolsky and Rosen who first suggested the problem of spooky action at a distance.

The only non-paradoxical way entanglement and its collapse can be realised physically, especially in the case of space-like separated detectors, as in fig 72(8) is this:

- (A) The closer detector, say No. 1 destructively collapses the entanglement at (1) sending a non-entangled advanced confirmation wave back in time to the source.
- (B) The arrival of the advanced wave at the source collapses the wave right at source, so that the retarded wave from the source is no longer entangled although it was prepared as entangled by the experimenter. This IS instantaneous but entirely local.
- (C) The retarded offer wave from the Bell experiment is no longer actually entangled and is sent at light speed to detector 2 where if it is detected it immediately has complementary polarisation to 1.
- (D) If detector 1 does not record a photon at the given angle no confirmation wave is sent back to the source, so no coincidence measurement can be made.
- (E) The emitted retarded wave will remain entangled unless photon 1 is or has been absorbed by another atom but then no coincidence counts will be made either.
- (F) The process is relativistically covariant. In an experimenter frame if relative motion results in detector 2 sampling first, the roles of 1 and 2 become exchanged and the same explanation follows.

Every detection at (2) either collapses the entangled wave, or the already partially collapsed single particle wave function as in (B): If no detection has happened at 1, or anywhere else, the retarded source wave is still entangled, and detector 2 may sample it and collapse the entanglement. If a detection of photon 1 has happened elsewhere or at detector 1 the retarded source wave is no longer entangled, as in B above and then detector 2, if it samples photon 2, also collapses this non-entangled single particle wave function.

So there is no light-speed violating information transfer directly from 1 to 2 resulting in paradox, but there is a deeper paradox about advanced and retarded waves in space time in the transactional principle. This as far as I can see gives the complete true real time account of how the universe actually deals with entanglement, not the fully collapsed statistical result the experimenter sees, and conveniently figures the case is already closed.

The standard account of the Bell theorem experiment, as in (8) cannot explain how the universe actually does it, only that the statistical correlation agrees with the sinusoidal angular dependence of quantum reality and violates the Bell inequality. The experimenter is in a privileged position to overview the total data and can conclude this with no understanding of how an entangled wave function they prepared can arrive at detector 2 unentangled when photon 1 has already been absorbed.

Richard Feynman's (1965) Nobel Lecture "The Development of the Space-Time View of Quantum Electrodynamics" opened the whole transactional idea of advanced and retarded waves twenty years before Cramer (1983) did. It enshrines the very principle before QED got completed as the most accurate theory ever.

The same applies to single particle wave functions, where collapse of the wave function on absorption has to paradoxically result in a sudden collapse of the wave function to zero even at space-like intervals from the emission and absorption loci, but the advanced and retarded confirmation and offer waves. Quantum mechanics also allows events to happen with no definite causal order (Goswami et al. 2018).

As just noted, the process of wave function collapse has generally been considered to violate Lorenz relativistic invariance (Barrett 1999 p44-45):

The standard collapse theory, at least, really is incompatible with the theory of relativity in a perfectly straightforward way: the collapse dynamics is not Lorentz-covariant. When one finds an electron, for example, its wave function instantaneously goes to zero everywhere except where one found it. If this did not happen, then there would be a nonzero probability of finding the electron in two places at the same time in the measurement frame. The problem is that we cannot describe this process of the wave function going to zero almost everywhere simultaneously in a way that is compatible with relativity. In relativity there is a different standard of simultaneity for each inertial frame, but if one chooses a particular inertial frame in order to describe the collapse of the wave function, then one violates the requirement that all physical processes must be described in a frame-independent way.

However Kastner (2021a,b) elucidates the relativistic transactional interpretation, which claims to resolve this through causal sets (Sorkin 2003) invoking a special-relativistic theory encompassing both real particle exchange and collapse:

In formal terms, a causal set C is a finite, partially ordered set whose elements are subject to a binary relation $<$ that can be understood as precedence; the element on the left precedes that on the right. It has the following properties:

- (i) transitivity: $(\forall x, y, z \in C)(x < y < z \Rightarrow x < z)$ (ii) irreflexivity: $(\forall x \in C)(x \not\sim x)$*
- (iii) local finiteness: $(\forall x, z \in C)$ (cardinality $\{y \in C \mid x < y < z\} < \infty$)*

Properties (i) and (ii) assure that the set is acyclic, while (iii) assures that the set is discrete. These properties yield a directed structure that corresponds well to temporal becoming, which Sorkin describes as follows:

In Sorkin's construct, one can then have a totally ordered subset of connected links (as defined above), constituting a chain. In the transactional process, we naturally get a parent/child relationship with every transaction, which defines a link. Each actualized transaction establishes three things: the emission event E, the absorption event A, and the invariant interval I(E,A) between them, which is defined by the transferred photon. Thus, the interval I(E,A) corresponds to a link. Since it is a photon that is transferred, every actualized transaction establishes a null interval, i.e., $ds^2 = c^2t^2 - r^2 = 0$. The emission event E is the parent of the absorption event A (and A is the child of E).

A major advantage of the causal set approach as proposed by Sorkin and collaborators ... is that it provides a fully covariant model of a growing spacetime. It is thus a counterexample to the usual claim (mentioned in the previous section) that a growing spacetime must violate Lorentz covariance. Specifically, Sorkin shows that if the events are added in a Poissonian manner, then no preferred frame emerges, and covariance is preserved (Sorkin 2003, p. 9). In RTI, events are naturally added in a Poissonian manner, because transactions are fundamentally governed by decay rates (Kastner and Cramer, 2018).

Ruth Kastner comments in private communication in relation to her development of the transactional interpretation:

The main problem with the standard formulation of QM is that consciousness is brought in as a kind of 'band-aid' that does not really work to resolve the Schrodinger's Cat and Wigner's Friend of paradoxes. The transactional picture, by way of its natural non-unitarity (collapse under well-quantified circumstances), resolves this problem and allows room for consciousness to play a role as the acausal/volitional influence that corresponds to efficacy (Kastner 2016). My version of TI, however, is ontologically different from Cramer's and it also is fully relativistic (Kastner 2021a,b). For specifics on why many recent antirealist claims about the world as alleged implications of Wigner's Friend are not sustainable, see Kastner (2021c). In particular, standard decoherence does not yield measurement outcomes, so one really needs real non-unitarity in order to have correspondence with experience. I have also shown that the standard QM formulation, lacking real non-unitarity, is subject to fatal inconsistencies (Kastner 2019, 2021d). These inconsistencies appear to infect Everettian approaches as well.

Kastner (2011) explains the arrow of time as a foundational quantum symmetry-breaking:

Since the direction of positive energy transfer dictates the direction of change (the emitter loses energy and the absorber gains energy), and time is precisely the domain of change (or at least the construct we use to record our experience of change), it is the broken symmetry with respect to energy propagation that establishes the directionality or anisotropy of time. The reason for the 'arrow of time' is that the symmetry of physical law must be broken: 'the actual breaks the symmetry of the potential.' It is often viewed as a mystery that there are irreversible physical processes and that radiation diverges toward the future. The view presented herein is that, on the contrary, it would be more surprising if physical processes were reversible, because along with that reversibility we would have time-symmetric (isotropic) processes, which would fail to transfer energy, preclude change, and therefore render the whole notion of time meaningless.

Kastner is a possibilist who argues that OWs and CWs are possibilities that are "real." She says that they are less real than actual empirically measurable events, but more real than an idea or concept in a person's mind. She suggests the alternate term "potentia," Aristotle's term that she found Heisenberg had cited. For Kastner, the possibilities are physically real as compared to merely conceptually possible ideas that are consistent with physical law. But she says the "possibilities" described by offer and confirmation waves are "sub-empirical" and pre-spatiotemporal (i.e., they have not shown up as actual in spacetime). She calls these "incipient transactions." She calls for a new metaphysical category to describe "not quite actual...possibilities."

Kastner (2012, 2014b) sets out the basis for extending the possibilist transactional interpretation or PTI, to the relativistic domain in relativistic transactional interpretation or RTI. This modified version proposes that offer and confirmation waves (OW and CW) exist in a sub-empirical, pre-spacetime realm (PST) of possibilities, and that it is actualised transactions which establish empirical spatiotemporal events. PTI proposes a growing universe picture, in which actualised transactions are the processes by which spacetime events are created from a substratum of quantum possibilities. The latter are taken as the entities described by quantum states (and their advanced confirmations); and, at a subtler relativistic level, the virtual quanta. PTI proposes a growing universe picture, in which actualised transactions are the processes by which spacetime events are created from a substratum of quantum possibilities.

The basic idea is that offers and confirmations are spontaneously elevated forms of virtual quanta, where the probability of elevation is given by the decay rate for the process in question. In the direct action picture of PTI, an excited atom decays because one of the virtual photon exchanges ongoing between the excited electron and an external absorber (e.g. electron in a ground state atom) is spontaneously transformed into a photon offer wave that generates a confirming response. The probability for this occurrence is the product of the QED coupling constant α and the associated transition probability. In quantum field theory terms, the offer wave corresponds to a 'free photon' or excited state of the field, instantiating a Fock space state (Kastner 2014b).

In contrast, with standard QFT where the amplitudes over all interactions are added and then squared under the Born rule, according to PTI, the absorption of the offer wave generates a confirmation (the 'response of the absorber'), an advanced field. This field can be consistently reinterpreted as a retarded field from the vantage point of an 'observer' composed of positive energy and

experiencing events in a forward temporal direction. The product of the offer (represented by the amplitude) and the confirmation (represented by the amplitude's complex conjugate) corresponds to the Born Rule.

Kastner (2014a, 2021c,d) deconstructs decoherence as well as quantum Darwinism, refuting claims that the emergence of classicality proceeds in an observer-independent manner in a unitary-only dynamics, noting that quantum Darwinism holds that the emergence of classicality is not dependent on any inputs from observers, but that it is the classical experiences of those observers that the decoherence program seeks to explain from first principles:

"in the Everettian picture, everything is always coherently entangled, so pure states must be viewed as a fiction -- but that means that it is also fiction that the putative 'environmental systems' are all randomly phased. In helping themselves to this phase randomness, Everettian decoherentists have effectively assumed what they are trying to prove: macroscopic classicality only 'emerges' in this picture because a classical, non-quantum-correlated environment was illegitimately put in by hand from the beginning. Without that unjustified presupposition, there would be no vanishing of the off-diagonal terms"

She extends this to an uncanny observation concerning the Everett view:

"That is, MWI does not explain why Schrodinger's Cat is to be viewed as 'alive' in one world and 'dead' in another, as opposed to 'alive + dead' in one world and 'alive – dead' in the other."

Kastner (2016a) notes that the symmetry-breaking of the advanced waves provides an alternative explanation to von Neumann's citing of the consciousness of the observer in quantum measurement:

Von Neumann noted that this Process 1 transformation is acausal, nonunitary, and irreversible, yet he was unable to explain it in physical terms. He himself spoke of this transition as dependent on an observing consciousness. However, one need not view the measurement process as observer-dependent. ... The process of collapse precipitated in this way by incipient transactions [competing probability projection operator weightings of the] absorber response(s) can be understood as a form of spontaneous symmetry breaking.

Kastner & Cramer (2018) confirm this picture:

And since not all competing possibilities can be actualized, symmetry must be broken at the spacetime level of actualized events. The latter is the physical correlate of non-unitary quantum state reduction.

However, in Kastner (2016b), she considers observer participation as integral, rejecting two specific critiques of libertarian, agent-causal free will: (i) that it must be anomalous or "antiscientific"; and (ii) that it must be causally detached from the choosing agent. She asserts that notwithstanding the Born rule, quantum theory may constitute precisely the sort of theory required for a nomic grounding of libertarian free will.

Kastner cites Freeman Dyson's comment rejecting epiphenomenalism:

I think our consciousness is not just a passive epiphenomenon carried along by the chemical events in our brains, but is an active agent forcing the molecular complexes to make choices between one quantum state and another. In other words, mind is already inherent in every electron, and the processes of human consciousness differ only in degree but not in kind from the processes of choice between quantum states which we call "chance" when they are made by electrons."

Kastner then proposes, not just a panpsychic quantum reality but a pan-volitional basis for it:

Considering the elementary constituents of matter as imbued with even the minutest propensity for volition would, at least in principle, allow the possibility of a natural emergence of increasingly efficacious agent volition as the organisms composed by them became more complex, culminating in a human being. And allowing for volitional causal agency to enter, in principle, at the quantum level would resolve a very puzzling aspect of the indeterminacy of the quantum laws—the seeming violation of Curie's Principle in which an outcome occurs for no reason at all. This suggests that, rather than bearing against free will, the quantum laws could be the ideal nomic setting for agent-causal free will.

Kastner, Kauffman & Epperson (2018) formalise the relationship between potentialities and actualities into a modification of Descartes *res cogitans* (purely mental substance) and *res extensa* (material substance) to *res potentiae* and *res extensa* comprising the potential and actual aspects of ontological reality. Unlike Cartesian dualism these are not separable or distinct but are manifest in all situations where the potential becomes actual, particularly in the process of quantum measurement in PTI, citing (McMullin 1984) on the limits of imagination of the *res potentiae*:

... imaginability must not be made the test for ontology. The realist claim is that the scientist is discovering the structures of the world; it is not required in addition that these structures be imaginable in the categories of the macroworld.

They justify this by noting that human evolutionary survival has depended on dealing with the actual, so the potential may not be imaginable in our conscious frame of reference, however one can note that the strong current of animism in human cultural history suggests a strong degree of focus on the potential, and its capacity to become actual in hidden unpredictable sources of accident or misfortune. In addition to just such unexpected real world examples, they note the applicability of this to a multiplicity of quantum phenomena:

Thus, we propose that quantum mechanics evinces a reality that entails both actualities (res extensa) and potentia (res potentia), wherein the latter are as ontologically significant as the former, and not merely an epistemic abstraction as in classical mechanics. On this proposal, quantum mechanics IS about what exists in the world; but what exists comprises both possibles and actuals. Thus, while John Bell's insistence on "beables" as opposed to just "observables" constituted a laudable return to realism about quantum theory in the face of growing instrumentalism, he too fell into the default actualism assumption; i.e., he assumed that to 'be' meant 'to be actual,' so that his 'beables' were assumed to be actual but unknown hidden variables.

What the EPR experiments reveal is that while there is, indeed, no measurable nonlocal, efficient causal influence between A and B, there is a measurable, nonlocal probability conditionalization between A and B that always takes the form of an asymmetrical internal relation. For example, given the outcome at A, the outcome at B is internally related to that outcome. This is manifest as a probability conditionalization of the potential outcomes at B by the actual outcome at A.

Nonlocal correlations such as those of the EPR entanglement experiment below can thus be understood as a natural, mutually constrained relationship between the kinds of spacetime actualities that can result from a given possibility – which itself is not a spacetime entity. She quotes Anton Zellinger (2016):

...it appears that on the level of measurements of properties of members of an entangled ensemble, quantum physics is oblivious to space and time .

Kastner (2021b), considers how the spacetime manifold emerges from a quantum substratum through the transactional process (fig 72(6)), in which spacetime events and their connections are established. The usual notion of a background spacetime is replaced by the quantum substratum, comprising quantum systems with non-vanishing rest mass, corresponding to internal periodicities that function as internal clocks defining proper times and in turn, inertial frames that are not themselves aspects of the spacetime manifold.

Three years after John Cramer published the transactional interpretation, I wrote a highly speculative paper, "Dual-time Supercausality (King 1989, Vannini 2006), based on John's description which says many of the same things emergent in Ruth Kastner's far more comprehensive development. Summing up the main conclusions we have:

- (1) **Symmetric-Time:** *This mode of action of time involves a mutual space-time relationship between emitter and absorber. Symmetric-time determines which, out of the ensemble of possibilities predicted by the probability interpretation of quantum mechanics is the actual one chosen. Such a description forms a type of hidden-variable theory explaining the selection of unique reduction events from the probability distribution. We will call this bi-directional causality transcausality.*
- (2) **Directed-time:** *Real quantum interaction is dominated by retarded-time, positive-energy particles. The selection of temporal direction is a consequence of symmetry-breaking, resulting from energy polarization, rather than time being an independent parameter. The causal effects of multi-particle ensembles result from this dominance of retarded radiation, as an aspect of symmetry-breaking.*

Dual-time is thus a theory of the interaction of two temporal modes, one time-symmetric which selects unique events from ensembles, and the other time-directed which governs the consistent retarded action of the ensembles. These are not contradictory. Each on their own form an incomplete description. Temporal causality is the macroscopic approximation of this dual theory under the correspondence principle. The probability interpretation governs the incompleteness of directed-causality to specify unique evolution in terms of initial conditions.

Quantum-consciousness has two complementary attributes, sentience and intent:

- (a) **Sentience** *represents the capacity to utilise the information in the advanced absorber waves and is implicitly transcausal in its basis. Because the advanced components of symmetric-time cannot be causally defined in terms of directed-time, sentience is complementary to physically-defined constraints.*
- (b) **Intent** *represents the capacity to determine a unique outcome from the collection of such absorber waves, and represents the selection of one of many potential histories. Intent addresses the two issues of free-will and the principle of choice in one answer – free-will necessarily involves the capacity to select one out of many contingent histories and the principle of choice manifests the essential nature of free-will at the physical level.*

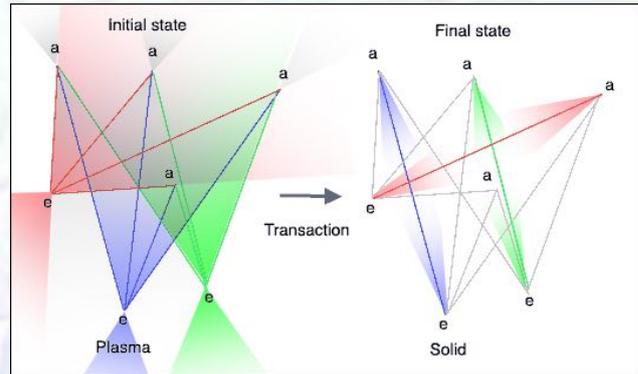

The transactional interpretation presents a unique view of cosmology, involving an implicit space-time anticipation in which a real exchange, e.g. a photon emitted by a light bulb and absorbed on a photographic plate or elsewhere, or a

Bell type entanglement experiment with two detectors, is split into an offer wave from the emitter and retro-causal confirmation waves from the prospective absorbers that, after the transaction is completed, interfere to form the real photon confined between the emission and absorption vertices. We also experience these retro-causal effects in weak quantum measurement, and delayed choice experiments.

To get a full picture of this process, we need to consider the electromagnetic field as a whole, in which these same absorbers are also receiving offer waves from other emitters, so we get a network of virtual emitter-absorber pairs.

There is a fundamental symmetry between creation and annihilation, but there is a sting in the measurement tail. When we do an interference experiment, with real positive energy photons, we know each photon came from the small region within the light source, but the locations of the potential absorbers affected by the wave function are spread across the world at large. The photon could be absorbed anywhere on the photographic plate, or before it, if it hits dust in the apparatus, or after if it goes right through the plate and out of the apparatus altogether, just as radioactive particles escape the exponential potential barrier of the nucleus. The problem concerning wave function collapse is which absorber?

Fig 73: A transaction modelled by a phase transition from a virtual plasma to a real interactive solid spanning space-time, in which the wave functions have now become like the harmonic phonons of solid state physics.

In all these cases once a potential absorber becomes real, all the other potential absorbers have zero probability of absorption, so the change occurs instantaneously across space-time to other prospective absorbers, relative to the successful one. This is the root problem of quantum measurement. Special relativistic quantum field theory is time symmetric, so solving wave function collapse is thus most closely realised in the transactional interpretation, where the real wave function is neither the emitter's spreading linear retarded wave, nor any of the prospective absorbers' linear advanced waves, but the results of a phase transition, in which all these hypothetical offer and confirmation waves resolve into one or more real wave functions linking creation and annihilation vertices. It is the nature of this phase transition and its non-linearity which holds the keys to life the universe and everything and potentially the nature of time itself.

The entire notion in Bell experiments, where communication between absorbers appears to be impossibly instantaneous, invoking super-luminal communication, is unnecessary because the retrocausal confirmation wave perfectly cancels the time elapse of the offer wave, so if detector 1 samples first, its confirmation goes back to the source photon-splitter arriving at the same time as the original emission and the offer wave collapses to a single photon emission to detector 2 which arrives there at exactly the time when 2 should have sampled the complementary polarisation, with this information as required. No superluminal interactions between absorbers occurs even if it looks like the process was instantaneous and would have to involve infinite velocity. This looks instantaneous without contradiction because of the time elapse cancellations, but if we follow it as a process, it is some kind of non-linear phase transition from a "plasma" state of offers and confirmations collapsing into a set of real photons with phonon like real excitations connecting them.

In Symbiotic Existential Cosmology this is envisaged as allowing a form of prescience because the collapse has implicit information about the future state of the universe in which the absorber exist. This may appear logically paradoxical but no classical information is transferred, so there is no inconsistency. Modelling the collapse appears to happen outside space-time, but actually it is instantaneous, so dual-time is just a core part of the heuristic to understand the non-linear process. This depends on transactional collapse being a non-random hidden-variable theory in which non-local correlations of the universal wave function manifest as a complex system during collapse in a way that looks deceptively like randomness because it is a complex chaotic ergodic process.

My perspective is that subjective conscious physical volition has to imbue an evolutionary advantage, or it would be evolutionarily unstable and ultimately be discarded by evolution, but this advantage has to involve real time anticipation of existential threats to survival. So I favour the transactional interpretation, in which a real particle e.g. a

photon is a superposition of a causal “offer wave” from an emitter complemented by potential retrocausal “confirmation waves” from absorbers. This is actually necessary, because the emission wave is a linear Schrödinger wave that spreads, but a real photon is an excitation between an emitter and an absorber, more like a simple harmonic phonon, non-linear in space with two foci as in fig 73.

I remain intrigued by the transactional principle because I am convinced that subjective consciousness is a successful form of quantum anticipation in space-time, (rather than classical prediction), that has enabled single-celled eucaryotes to conquer the biosphere before there were brains, which have evolved based on intimately-coupled societies of such cells (neurons and neuroglia) now forming the neural networks neuroscience tries to understand in classical causal terms. The eucaryote endo-symbiosis in this view marks a unique discrete topological transformation of the membrane to unfold attentive sentient consciousness invoking the second stage of cosmological becoming that ends up being us wondering what the hell is going on here? This is the foundation of emergence as quantum cosmology and it explains why we have the confounding existential dilemma we do have and why it all comes back to biospheric symbiosis being the centre of the cyclone of survival for us as a climax species.

The full picture of a transaction process is a population of real, or potential emitters in excited states and potential ground state absorbers, with their offer and confirmation wave functions extending throughout space time, as in the Feynman representation. As the transaction proceeds, this network undergoes a phase transition from a “virtual plasma” state to a “real solid”, in which the excited emitters are all paired with actual absorbers in the emitters’ future at later points in space-time. This phase transition occurs across space-time – i.e. **transcausally** – covering both space-like and time-like intervals. It has many properties of a phase transition from plasma to solid, with a difference – the strongest interactions don’t win, except with a probability determined by the relative power of the emitter’s wave amplitudes at the prospective absorption event. This guarantees the transaction conforms to the emitter’s probability distribution and the absorber’s one as well. If a prospective absorber has already interacted with another emitter, it will not appear in the transaction network at this space-time point, so ceases to be part of the collective transaction. Once this is the case, all other prospective absorbers of a given emitter scattered throughout space-time, both in the absorber’s past and future, immediately have zero probability of absorption from any of the emitters and no causal conflict, or time loop arises.

The transition is laterally across the whole of space-time, not along the arrow of time in either direction, so cannot exist within space-time and really needs a dual time parameter. This is why my 1989 paper was entitled “dual-time super-causality”. Now this doesn’t mean a transaction is just a random process. Rather, it is a kind of super-selection theory, in which the probability of absorption at an absorber conforms to the wave probability but the decision making process is spread between all the prospective absorbers distributed across space-time, not just an emitter-based random wave power normalised probability. The process is implicitly retro-causal in the same way weak quantum measurement and Wheeler’s delayed choice experiments are.

The fact that in the cat paradox experiment, we see only a live or dead cat and not a superposition doesn’t mean however, that conscious observers witness only a classical world view. There are plenty of real phenomena in which we do observe quantum superpositions, including quantum erasure and quantum recoherence, where entangled particles can be distinguished collapsing the entanglement, and then re-entangled. A laser consists of excited atoms above the ground state which can be triggered to coherently emit photons indistinguishably entangled in a superposition of in-phase states stimulated by a standing wave in the laser caught between pairs of reflecting mirrors, so we see the bright laser light and know it is a massive superimposed set of entangled photons.

In all forms of quantum entanglement experiment, when the state of one of the pair is detected, the informational outcome is “transmitted” instantaneously to the other detector so that the other particle’s state is definitively complementary, although the detectors can be separated by space-like as well as time-like intervals, and this transmission cannot be used to relay classical information. This again is explained by the transactional interpretation, because the confirmation wave of the first detector of the pair is transmitted retro-causally back to the source event where the splitting occurred and then causally out to the second detector where it now has obligately complementary spin or polarisation when detection occurs.

What the transactional interpretation does provide is a real collapse process in which the universe is neither stranded in an Everett probability multiverse, nor in a fully collapsed classical state, but can be anywhere in between, depending on which agents are doing the measuring in a given theory. Nor is collapse necessarily random and thus meaningless,

but is a space-time spanning non-linear phase transition, involving bidirectional hand-shaking between past and future. The absorbers are all in an emitter's future so there is a musical chairs dance happening in the future. And those candidates may also be absorbers of other emitters and so on, so one can't determine the ultimate boundary conditions of this problem. Somehow the "collapse", which we admit violates retarded causality, results in one future choice. This means that there is no prohibition on this being resolved by the future affecting the outcome because the actual choice has no relation to classical causality.

The only requirement is that repeated individual observations are asymptotic to the Born probability interpretation normalised by the wave function power $\phi \cdot \phi^*$, but this could arise from a variety of complex transcausal quasi- or pseudo-random processes, where multiple entanglements generate effective statistical noise, while having a basis in an explicit hidden variable theory. The reason for the Born asymptote could thus be simply that the non-linear phase transition of the transaction, like the cosmic wave function of the universe, potentially involves everything there is – the ultimate pseudo-random optimisation process concealing a predictive hidden variable theory. One should point out that that near universal assumption that the probability interpretation implies pure randomness normalised by the wave power has as much onus on scientific proof as does any hidden variable theory, such as transactional collapse.

It is also one in which subjective conscious volition and meaning can become manifest in cosmic evolution, in which the universe is in a state of dynamic ramification and collapse of quantum superpositions. The key point here is that subjective conscious volition needs to have an anticipatory property in its own right, independent of (although complementary to) brain based attention processes, or it will be discarded by natural selection, even if we do have free will, and would not have been selected for, all the way from founding eucaryotes to *Homo sapiens*. The transactional interpretation, by involving future absorbers in the collapse process, provides just such an anticipatory feature.

It is one thing to have free will and it's another to use free will for survival on the basis of (conscious) prediction, or anticipation. Our conscious brains are striving to be predictive to the extent that we are subject to flash-lag perceptual illusions where perceptual processes attempt, sometimes incorrectly, to predict the path of rapidly moving objects (Eagleman & Sejnowski 2000), so the question is pivotal. Anticipating future threats and opportunities is key to how we evolved as conscious organisms, and this is pivotal over short immediate time scales, like the snake's or tiger's strike which we survive. Anticipating reality in the present is precisely what subjective consciousness is here to do.

The **hardest problem of consciousness** is thus that, to be conserved by natural selection, subjective consciousness (a) has to be volitional i.e. affect the world physically to result in natural selection and (b) it has to be predictive as well. Free-will without predictivity is as neutral to evolution, as random behaviour, and it will not be selected for. If we are dealing with classical reality, we could claim this is merely a computational requirement, but why then do we have subjective experience at all? Why not just recursive predictive attention processes with no subjectivity?

Here is where the correspondence between sensitive dynamic instability at tipping points and quantum uncertainty comes into the picture. We know biology and particularly brain function is a dynamically unstable process, with sensitive instabilities that are fractal down to the quantum level of ion channels, enzyme molecules whose active sites are enhanced by quantum tunnelling and the quantum parallelism of molecular folding and interactive dynamics. We know that brain dynamics operating close to the edge of chaos is convergent to dynamic crisis during critical decision-making uncertainties that do not have an obvious computational, cognitive, or reasoned disposition. We also know at these points that the very processes of sensitivity on existing conditions and other processes, such as stochastic resonance, can allow effects at the micro level approaching quanta to affect the outcome of global brain states.

And those with any rational insight can see that, for both theoretical and experimental reasons, classical causal closure of the universe in brain dynamics is an unachievable quest. Notwithstanding Libet's attempt, there is no technological way to experimentally achieve verification that the brain is causally closed and it flies in the face of the fractal molecular nature of biological processes at the quantum level. Nevertheless we can understand that subjective conscious volition cannot enter into causal conflict with brain processes which have already established an effective computational outcome, as we do when we reach a prevailing reasoned conclusion, so free will is effectively restricted to situations where the environmental circumstances are uncertain, or not effectively computable, or perceived consciously to be anything but certain. This in turn means that the key role of free will is not applying it to rationally or emotionally foregone conclusions but to environmental and strategic uncertainties, especially involving other conscious agents whose outcomes become part of quantum uncertainty itself.

The natural conclusion is that conscious free will has been conserved by evolution because it provides an evolutionary advantage at anticipating root uncertainties in the quantum universe, including environmental and contextual uncertainties which are themselves products of quantum uncertainty amplified by unstable processes in the molecular universe such as quantum kinetic billiards. This seems almost repugnantly counter-intuitive, because we tend to associate quantum uncertainty and the vagaries of fate with randomness, but this is no more scientifically established than causal closure of the universe in brain function. All the major events of history that are not foregone conclusions, result from conscious free will applied to uncertainty, such as Nelson turning his blind eye to the telescope, in the eventually successful Battle of Copenhagen. So the question remains that when we turn to the role of subjective consciousness volition in quantum uncertainty, this comes down to not just opening the box of Schrödinger's cat, but to anticipating uncertain events more often than random chance would predict in real life.

That is where the transactional approach comes into its own, because, while the future at the time of casting the emission die is an indeterminate set of potential absorbers, the retro-causal information contained in the transaction is implicitly revealing which future absorbers are actually able to absorb the real emitted quantum and hence information about the real state of the future universe, not just its probabilities at emission. Therefore the transaction is carrying additional implicit "encoded" information about the actual future state of the universe and what its possibilities are that can be critical for survival in natural selection.

Although, like the "transmission" of a detection to the other detector in an entanglement experiment cannot be used to transfer classical information faster than the speed of light, the same will apply to quantum transactions, but this doesn't mean they are random or have no anticipatory value, just that they cannot be used for causal deduction.

Because the "holistic" nature of conscious awareness is an extension of the global unstable excitatory dynamics of individual eucaryote cells to brain dynamics, a key aspect of subjective consciousness may be that it becomes sensitive to the wave-particle properties of quantum transactions with the natural environment in the process of cellular quantum sentience, involving sensitivity to quantum modes, including photons, phonons and molecular orbital effects constituting cellular vision, audition and olfaction. Expanded into brain processes, this cellular quantum dynamics then becomes integral to the binding of consciousness into a coherent whole.

If we view neurodynamics as a fully quantum process, in the most exotic quantum material in the universe, in which the wave aspects consist of parallel excitation modes representing the competing possibilities of response to environmental uncertainties. If there is an open and shut case on logical, or tactical grounds, this mode will win out pretty much in the manner of Edelman's (1987) neural Darwinism or Dennett's (1991) multiple drafts. In terms of quantum evolution, the non-conscious processes form overlapping wave functions, proceeding according to deterministic Schrödinger solutions, (von Neumann type 2 processes), but in situations where subjective consciousness becomes critical to make an intuitive decision, the brain dynamic approaches an unstable tipping point, in which system uncertainty becomes pivotal (represented in instability of global states which are in turn sensitive to fractal scales of instability to the molecular level. Subjective consciousness then intervenes causing an intuitive decision through a (type 1 von Neumann) process of wave function collapse of the superimposed modes.

From the inside, this feels like and IS a choice of "free-will" aka subjective conscious volition over the physical universe. From the outside, this looks like collapse of an uncertain brain process to one of its eigenfunction states which then become apparent. There is a very deep mystery in this process because the physical process looks and remains uncertain and indeterminate, but from inside, in complete contradiction, it looks and feels like the exercise of intentional will determining future physical outcomes. So in a fundamental way it is like a Schrödinger cat experiment in which the cat survives more often than not, i.e. we survive. Now that is a really confounding issue at the very nub of what conscious existence is about and why SEC has the cosmological axiom of subjectivity to resolve it, because it is a fundamental cosmological paradox otherwise. So we end up with the ultimate paradox of consciousness how can we not only predict future outcomes that are quantum uncertain but capitalise on the ones that promote our survival, i.e. throw a live cat more often than chance would dictate!

This is the same dilemma that SEC addresses in primal subjectivity and is also in Cathy Reason's theorem ... from the physical point of view causal closure of the brain is an undecidable proposition because we can't physically prove conscious will has physical effect, but neither can we prove causal closure of the (classical) universe. On the other hand, as Cathy's theorem intimates, conscious self certainty implies we know we changed the universe. Certainty of will as well as certainty of self. So the subjective perspective is certain and the objective perspective is undecidable. In

exactly the same way, the cat paradox outcome is uncertain and can't be hijacked physically, but the autonomous intentional will used to tip the uncertain brain state has confidence of overall efficacy. This is the key to consciousness, free-will and survival in the jungle when cognition stops dead because of all the other conscious agents rustling in the grass and threatening to strike, which are uncomputable because they too are conscious! It's also the key to Psi, but in a more marginal way because it's trying to pass this ability back into the physical, where it drifts towards the probability interpretation. That's why I accept it, but don't abuse the siddhis by declaring them!

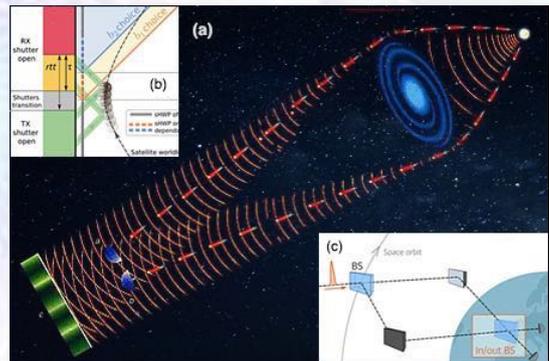

Consciousness is retained by evolution because it is a product of a Red Queen cognitive ⁴¹ race between predators and prey in a similar way to the way sexuality has become a self-perpetuating genetic race between parasites and hosts by creating individual variation, thus avoiding boom and bust epidemics.

Cramer (2022) notes a possible verifiable source of advanced waves:

In the 1940s, young Richard Feynman and his PhD supervisor John Wheeler decided to take the advanced solution seriously and to use it to formulate a new electromagnetism, now called Wheeler-Feynman absorber theory (WF). WF assumes that an oscillating electric charge produces advanced and retarded waves with equal strengths. However, when the retarded wave is subsequently absorbed (in the future), a cancellation occurs that erases all traces of the advanced waves and their time-backward "advanced effects." WF gives results and predictions identical to those of conventional electromagnetic theory. However, if future retarded-wave absorption is somehow incomplete, WF suggests that this absorption deficiency might produce experimentally observable advanced effects.

When Bajlo (2017) made measurements on cold, clear, dry days, he made the observations as the Earth rotated and the antenna axis swept across the galactic center, where wave-absorption variations might occur, in a number of these measurements, he observed strong advanced signals (6.94 to 26.5 standard deviations above noise) that arrived at the downstream antenna a time $2D/c$ before the main transmitted pulse signal. Variations in the advanced-signal amplitude as the antenna axis swept across the galactic center were also observed. The amplitude was reduced up to 50% of off-center maximum when pointed directly at the galactic center (where more absorption is expected.) These results constitute a credible observation of advanced waves.

Fig 74: Wheeler (1983) delayed choice experiment shows that different forms of measurement after light from a distant quasar has been gravitationally lensed around an intervening galaxy can be determined to have passed one or the other way around it or a superposition of both, depending on whether detection of one or other particle, or an interference is made when it reaches Earth. (b, c) An experimental implementation of Wheeler's idea along a satellite-ground interferometer that extends for thousands of kilometres in space (Vedovato et al. 2017), using shutters on an orbiting satellite.

Superdeterminism: There is another interpretation of quantum reality called super-determinism (Hossenfelder & Palmer 2020), which has an intriguing relationship with retro-causality and still can admit free will, despite the seeming contradiction in the title. Bell's theorem assumes that the measurements performed at each detector can be chosen independently of each other and of the hidden variables that determine the measurement outcome: $\rho(\lambda(ab)) = \rho(\lambda)$.

In a super-deterministic theory, this relation is not fulfilled $\rho(\lambda(ab)) \neq \rho(\lambda)$ because the hidden variables are correlated with the measurement settings. Since the choice of measurements and the hidden variable are predetermined, the results at one detector can depend on which measurement is done at the other without any need for information to travel faster than the speed of light. The assumption of statistical independence is sometimes referred to as the free choice or free will assumption, since its negation implies that human experimentalists are not free to choose which measurement to perform. But this is incorrect. What it depends on are the actual measurements made. For every possible pair of measurements a, b there is a predefined trajectory determined both by the particle emission and the measurement at the time absorption takes place. Thus in general the experimenter still has the free will to choose a, b or even to change the detector set up, as in the Wheeler delayed choice experiment in fig 74, and science proceeds as usual, but the outcome depends on the actual measurements made. In principle, super-determinism is untestable, as the correlations can be postulated to exist since the Big Bang, making the loophole impossible to eliminate. However this has an intimate relationship with the transactional interpretation and its implicit retro-causality, because it includes the absorbing conditions in the transaction, so the two are actually compatible.

⁴¹ the mental action or process of acquiring knowledge and understanding through thought, experience, and the senses.

Superdeterminism is distinct from theories which attempt to assert boundary conditions on the cosmic origin combined with time asymmetric laws about the cosmic wave function which would result in strong determinism, the notion that despite quantum uncertainty, the entire future of the universe is predetermined (Chen 2023).

Sabine (Hossenfelder 2020) points out exactly how superdeterminism can violate statistical independence:

I here want to explain how the strangeness disappears if one is willing to accept that one of the assumptions we have made about quantum mechanics is not realized in nature: Statistical Independence. Loosely speaking, Statistical Independence means that the degrees of freedom of spatially separated systems can be considered uncorrelated, so in a superdeterministic model they are generically correlated, even in absence of a common past cause. The way that Statistical Independence makes its appearance in superdeterminism is that the probability distribution of the hidden variables given the detector settings $\rho(\lambda|\vartheta)$ is not independent of the detector settings, ie $\rho(\lambda|\vartheta) \neq \rho(\lambda)$. What this means is that if an experimenter prepares a state for a measurement, then the outcome of the measurement will depend on the detector settings. The easiest way to think of this is considering that both the detector settings, ϑ , and the hidden variables, λ , enter the evolution law of the prepared state. As a consequence, ϑ and λ will generally be correlated at the time of measurement, even if they were uncorrelated at the time of preparation. Superdeterminism, then, means that the measurement settings are part of what determines the outcome of the time-evolution of the prepared state. What does it mean to violate Statistical Independence? It means that fundamentally everything in the universe is connected with everything else, if subtly so. You may be tempted to ask where these connections come from, but the whole point of superdeterminism is that this is just how nature is. It's one of the fundamental assumptions of the theory, or rather, you could say one drops the usual assumption that such connections are absent. The question for scientists to address is not why nature might choose to violate Statistical Independence, but merely whether the hypothesis that it is violated helps us to better describe observations.

However, the “toy” superdeterministic hidden variable theory (Donadi & Hossenfelder 2022) uses “the master equation for one of the most common examples of decoherence – amplitude damping in a two-level system”. But decoherence is a theory in which an additional term is added to model the increasing probability of a quantum getting hit by another quantum and literally uses forced damping to suppress the entangled “off diagonal” components of the wave function matrix.

Schreiber (1995) sums up the case for consciousness collapsing the wave function as follows:

“The rules of quantum mechanics are correct but there is only one system which may be treated with quantum mechanics, namely the entire material world. There exist external observers which cannot be treated within quantum mechanics, namely human (and perhaps animal) minds, which perform measurements on the brain causing wave function collapse.”

Henry Stapp’s (2001) comment is pertinent to the cosmology I am propounding, because it implies that the place where collapse occurs lies in the brain making quantum measurements of its own internal states:

“From the point of view of the mathematics of quantum theory it makes no sense to treat a measuring device as intrinsically different from the collection of atomic constituents that make it up. A device is just another part of the physical universe... Moreover, the conscious thoughts of a human observer ought to be causally connected most directly and immediately to what is happening in his brain, not to what is happening out at some measuring device... Our bodies and brains thus become ... parts of the quantum mechanically described physical universe. Treating the entire physical universe in this unified way provides a conceptually simple and logically coherent theoretical foundation...”

Quantum entanglement is another area where consciousness may have a critical role. Einstein, Podolsky and Rosen (1935) proposed a locally causal limitation on any hidden variable theories describing the situation when two particles were entangled coherently in a single wave function. For example an excited calcium atom, because of the two electrons in its outer shell, can emit two (yellow and blue) photons of complementary spin in a single transition from zero to zero spin outer shells. Bell’s (1966) theorem demonstrated a discrepancy between locally-causal theories, in which information between hidden sub-quantum variables could not be transferred faster than light. However, multiple experiments using Bell’s theorem have found the polarisations, or other quantum states of the particles, such as spin, are correlated in ways violating local causality which are not limited by the velocity of light (Aspect et al. 1982). This “spooky action at a distance” which Einstein disliked shows that the state of either particle remains indeterminate until we measure one of them, when the other’s state is the instantaneously determined to be complementary. This cannot however be used to send logical classical information faster than light, or backwards in time, but it indicates that the quantum universe is a highly entangled system in which potentially all particles in existence are involved.

Entanglement, Measurement and Phase Transition

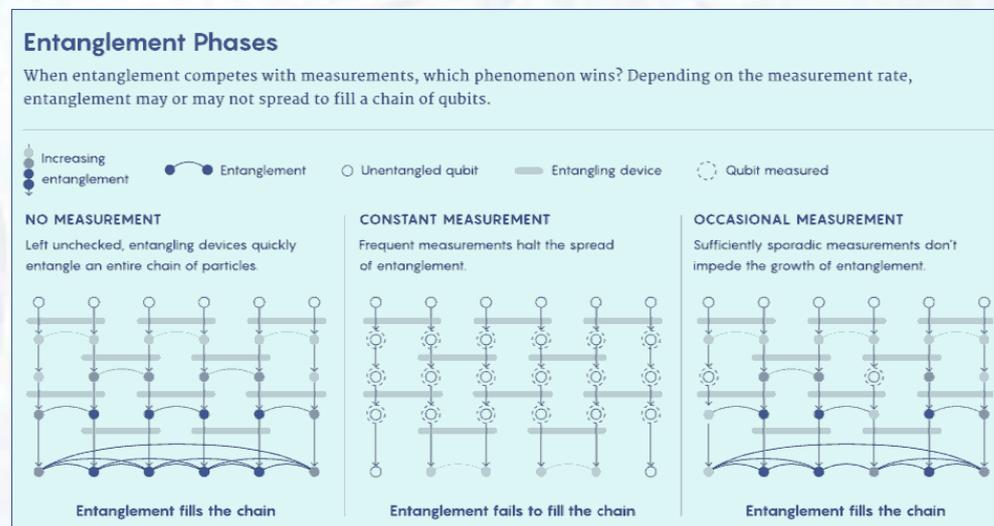

A flurry of theoretical and experimental research has uncovered a strange new face of entanglement, that shows itself not in pairs, but in constellations of particles (Wood 2023). Entanglement naturally spreads through a group of

particles, establishing an intricate web of contingencies. But if you measure the particles frequently enough, destroying entanglement in the process, you can stop the web from forming. In 2018, three groups of theorists (Chan A et al. 2019, Li et al. 2018, Skinner et al. 2019) showed that these two states — web or no web — are reminiscent of familiar states of matter such as liquid and solid. But instead of marking a transition between different structures of matter, the shift between web and no web indicates a change in the structure of information.

This is a phase transition in information, it's where the properties in information — how information is shared between things — undergo a very abrupt change. Brian Skinner

More recently, a separate trio of teams tried to observe that phase transition in action (Choi et al. 2020). They performed a series of meta-experiments to measure how measurements themselves affect the flow of information. In these experiments, they used quantum computers to confirm that a delicate balance between the competing effects of entanglement and measurement can be reached. The transition's discovery has launched a wave of research into what might be possible when entanglement and measurement collide. Matthew Fisher, a condensed matter physicist at the University of California, Santa Barbara, started studying the interplay of measurement and entanglement because he suspects that both phenomena could play a role in human cognition.

Fig 74b: Entanglement phase transition and Measurement

Since a measurement tends to destroy the "quantumness" of a system, it constitutes the link between the quantum and classical world. And in a large system of quantum bits of information, or qubits, the effect of measurements can induce emergence of

new phases of quantum information. When the qubits interact with one another, their information becomes shared non-locally in an entangled state, but under measurement, the entanglement is destroyed. The battle between measurement and interactions leads to two distinct phases: one where interactions dominate and entanglement is widespread, and one where measurements dominate, and entanglement is suppressed. Roushan et al. (2023) have now observed the crossover between these two regimes in a system of up to 70 qubits and also saw signatures of a novel form of "quantum teleportation"—in which an unknown quantum state is transferred from one set of qubits to another — that emerges as a result of these measurements. When measurements dominated over interactions (the "disentangling phase"), the strands of the web remained relatively short. The probe qubit was only sensitive to the noise of its nearest qubits. In contrast, when the measurements were weaker and entanglement was more widespread (the "entangling phase") the probe was sensitive to noise throughout the entire system. The crossover between these two sharply contrasting behaviours is a signature of the sought-after measurement-induced phase transition. Matsushita & Hofmann (2023) show this also depends on the strength of the back-action on the system of the measurement interaction. Eigenvalues emerge when the quantum interferences between different back-actions correspond to a Fourier transform in the back-action parameter.

The Greenberger–Horne–Zeilinger state (Greenberger, Horne & Zeilinger 1989, Mermin 1990) is one of several three-particle entanglements that have become pivotal in quantum computing (Hussein et al. 2023). There is no standard measure of multi-partite entanglement because different, not mutually convertible, types of multi-partite entanglement exist. Nonetheless, many measures define the GHZ state to be maximally entangled state. The GHZ state

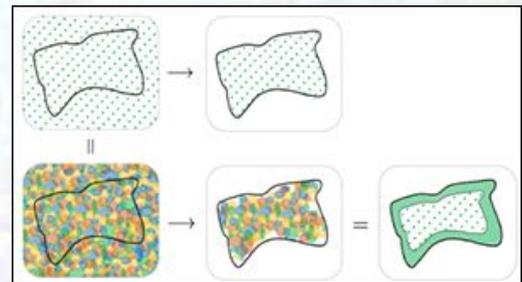

$|\text{GHZ}\rangle = \frac{|000\rangle + |111\rangle}{\sqrt{2}}$ and the W state $|\text{W}\rangle = \frac{1}{\sqrt{3}}(|001\rangle + |010\rangle + |100\rangle)$ represent two non-biseparable classes of 3-qubit states, which cannot be transformed (not even probabilistically) into each other by local quantum operations. This three particle entanglement problem is reminiscent of classical gravitation, which has a two body inverse square law, that in the three-body problem becomes intractably complex and chaotic as Henri Poincare found out. There is no general closed-form solution to the three-body problem, i.e. no general solution that can be expressed in terms of a finite number of standard mathematical operations.

Measuring Quantumness: Entanglement, Magic and Interactivity

Understanding how quantum entanglement can open new capacities for quantum computing (Wood 2023b), can help us understand the way biological conscious brains can anticipate reality revolves around the question of what kinds of quantum system can or can't be simulated by classical computers in polynomial time and not suffer the multiple exponential runaway, illustrated in Shor's (1994) quantum algorithm for cracking encryption problems.

Fig 74c: Using symmetry-protected magic to study the complexity of symmetry-protected topological (SPT) phases of matter (Ellison et al. 2021).

The ability of subsequently discovered classical computational algorithms to classically simulate quantum computing seemed like a bit of a miracle, but the first successful classical algorithm (Gottesman 1998) couldn't handle all quantum circuits, just those that stuck to Clifford gates. Jozsa & Linden (2002) then proved that, so long as their algorithm simulated a circuit that didn't entangle qubits, it could handle larger and larger numbers of qubits without taking an exponentially longer time, showing entanglement itself was a measure of quantumness.

"Nature isn't classical, dammit, and if you want to make a simulation of nature, you'd better make it quantum mechanical." Richard Feynman (1982)

Then entered "quantum magic". If you added a "T gate," a seemingly innocuous operation that rotates a qubit in a particular way, their algorithm would choke on it. The T gate seemed to manufacture something intrinsically quantum that can't be simulated on a classical computer. Bravyi and Gosset in 2016 developed a classical algorithm for simulating so-called low-magic circuits, giving the quantum essence produced by the forbidden T-gate rotation the catchy name: magic. But this configuration is not just confined to arcane quantum computing configurations. Ellison et al. (2021) identified certain phases of quantum matter that are guaranteed to have magic, just as many phases of matter have particular patterns of entanglement.

Yet another form of quantumness had already been discovered earlier. Much as Gottesman-Knill had focused on circuits without entangling gates, and Bravyi and Gosset could cut through circuits without too many T gates, Valiant's (2001) algorithm was restricted to circuits that lacked the "swap gate" – an operation that takes two qubits and exchanges their positions. As long as you don't exchange qubits, you can entangle them and infuse them with as much magic as you like, and you'll still find yourself on yet another distinct classical island. But as soon as you start shuffling qubits around, you can work wonders beyond the ability of any classical computer.

In 1984, Valiant's "probably approximately correct" (PAC) model mathematically defined the conditions under which a mechanistic system could be said to "learn" information. Valiant (2013) generalised his PAC learning framework to encompass biological evolution as well. He broadened the concept of an algorithm into an "ecorithm," which is a learning algorithm that "runs" on any system capable of interacting with its physical environment. Algorithms apply to computational systems, but ecorithms can apply to biological organisms or entire species. The concept draws a computational equivalence between the way that individuals learn and the way that entire ecosystems evolve. In both cases, ecorithms describe adaptive behaviour in a purely mechanistic way:

"An ecorithm is an algorithm, but its performance is evaluated against input it gets from a rather uncontrolled and unpredictable world. And its goal is to perform well in that same complicated world." (Leslie Valiant).

Valiant is a devoted mechanist who sees no difference between the conscious brain and AI, reducing everything to computational mathematics. When asked (Pavlus 2016): *"What if the ecorithms governing evolution and learning are*

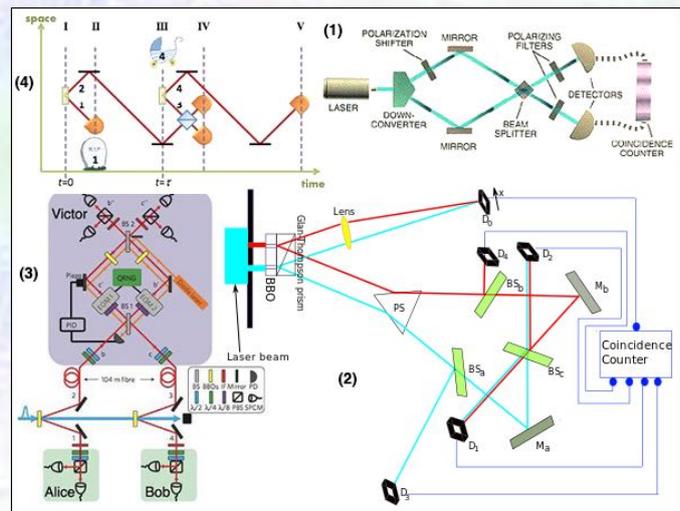

unlearnable?" He acknowledges: "It's a logical possibility, but I don't think it's likely at all. I think it's going to be something pretty tangible and reasonably easy to understand. We can ask the same question about fundamental unsolved problems in mathematics".

Terhal and DiVincenzo (2001) almost immediately uncovered the source of that power. They showed that Valiant's swap-gate-free "matchgate" circuits, were simulating a well-known class of physics problems, similar to how computers simulate growing galaxies or nuclear reactions. Matchgate circuits simulate a group of fermions. When swap gates are not used, the simulated fermions are noninteracting, or "free." Problems involving free electrons are relatively easy for physicists to solve, but when swap gates are used, the simulated fermions interact, crashing together and doing other complicated things. These problems are extremely hard, if not unsolvable. Conceptually, this resource corresponds to "interactivity" — or how much the simulated fermions can sense each other.

In the 1990s, the physical ingredient that made quantum computers powerful seemed obvious. It had to be entanglement, the "spooky" quantum link between distant particles that Erwin Schrödinger himself identified as "the characteristic trait of quantum mechanics." When Gottesman developed his method of simulating Clifford circuits, he based it on the "operator" quantum mechanics developed by Werner Heisenberg. Restricting one's view to free fermions involves viewing quantum mechanics through yet another mathematical lens. Each captures certain aspects of quantum states, but at the price of garbling some other quantum property.

If a collection of qubits is largely **unentangled**, has **little magic**, or simulates a bunch of **nearly free fermions**, then researchers know they can reproduce its output on a classical laptop. Any quantum circuit with a low score on one of these three quantum metrics lies in the shallows just off the shores of a classical island, in the space of possible phases of Matter (Wolchover 2018) and won't be the next Shor's algorithm.

Fig75: (1) Quantum Erasure shows it is also possible to 'uncollapse' or erase such losses of entangled correlation by re-interfering the wave functions so we can no longer tell the difference. The superposition choices of the delayed choice experiment fig 74, also do this. Erasure successfully recreates the lost correlations, detecting information about one of the particles and then erasing it again by re-interfering it back into the shared wave function provided we use none of its information. Pairs of identically polarised correlated photons produced by a 'down-converter', bounce off mirrors, converge again at a beam splitter and pass into two detectors. A coincidence counter observes an interference pattern in the rate of simultaneous detections by the two detectors, indicating that each photon has gone both ways at the beam splitter, as a wave. Adding a polarisation shifter to one path destroys the pattern, by making it possible to distinguish the photons' paths. Placing two polarising filters in front of the detectors makes the photons identical again, erasing the distinction, restoring the interference pattern. (2) Delayed choice quantum eraser configuration. An individual photon goes through one (or both) of the two slits. One of the photons - the "signal" photon (red and blue lines) continues to the target detector D0, which is scanned in steps along its x-axis. A plot of "signal" photon counts detected by D0 versus x can be examined to discover whether the cumulative signal forms an interference pattern. The other entangled photon - the "idler" photon (red and blue lines going downwards from the prism), is deflected by prism PS that sends it along divergent paths depending on whether it came from slit A or slit B. Detection of the idler photon by D3 or D4 provides delayed "which-path information" indicating whether the signal photon with which it is entangled had gone through slit A or B. On the other hand, detection of the idler photon by D1 or D2 provides a delayed indication that such information is not available for its entangled signal photon. Insofar as which-path information had earlier potentially been available from the idler photon, the information has been subjected to a "delayed erasure". (3) Delayed choice entanglement swapping, in which Victor is able to decide whether Alice's and Bob's photons are entangled or not after they have already been measured. (Ma et al. 2002). (4) A photon is entangled with a photon that has already died (been sampled) even though they never coexisted at any point in time (Megidish 2012).

Phenomena, including delayed choice quantum erasure and entanglement-swapping fig 75, demonstrate that the time of a quantum observation can be ambiguous or possibly stand outside space-time, as the transactional picture suggests. The Wigner's friend experiment of fig 76c likewise shows that quantum path information can also take the form of a quantum measurement 'observer'. Narasimhan, Chopra & Kafatos M (2019) draw particular attention to Kim et al. (2000) in regard to a "universal observer" integrating individual conscious observers and their observations:

While traditional double-slit experiments are usually interpreted as indicating that the collapse of the wave function involves choices by an individual observer in space-time, the extension to quantum eraser experiments brings in some additional subtle aspects relating to the role of observation and what constitutes an observer. Access to, and the interpretation of, information outside space and time may be involved. This directly ties to the question of where the Heisenberg-von Neumann cut is located and what its nature is. ... There is a possibility that individual observers making choices in space and time are actually aspects of the universal Observer, a state masked by assumptions about individual human minds that may need further development and re-examination.

Consciousness and Measurement

Summing up the position of physicists in a survey of participants in a foundations of quantum mechanics gathering, Schlosshauer et al. (2013) found that, while only 6% of physicists present believed consciousness plays a distinguished physical role in measurement, a majority believed it has a fundamental, although not distinguished role in the application of the formalism. They noted in particular that *“It is remarkable that more than 60% of respondents appear to believe that the observer is not a complex quantum system.”* Indeed on all counts queried there were wide differences of opinion, including which version of quantum mechanics they supported. Since all of the approaches are currently consistent with the predictions of quantum mechanics, these ambiguous figures are not entirely surprising.

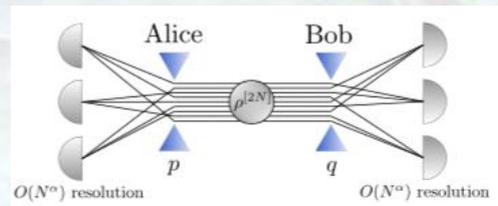

In an experiment to test the influence of conscious perception on quantum entanglement (Radin, Bancel & Delorme 2021), explored psychophysical (mind-matter) interactions with quantum entangled photons. Entanglement correlation strength measured in real-time was presented via a graph or dynamic images displayed on a computer monitor or web browser. Participants were tasked with mentally influencing that metric, with particularly strong results observed in three studies conducted ($p < 0.0002$). Radin, Michel & Delorme (2016) also reported a σ 5.72 ($p = 1.05 \times 10^{-8}$) deviation from a null effect in which participants focused their attention toward or away from a feedback signal linked in real time to the double-slit component of an interference pattern, suggesting consciousness affecting wave function collapse. For a review, see Milojevic & Elliot (2023). Radin (2023) has also reported σ 7.3 result beyond chance ($p=1.4 \times 10^{-13}$) deviations leaving little doubt that on average anomalous deviations in the random data emerged during events that attracted widespread attention, from a network of electronic random number generators located around the world that continuously recorded samples, used to explore a hypothesis that predicts the emergence of anomalous structure in randomness correlated with events that attract widespread human attention. Mossbridge et al. (2014) have also cited an organic unconscious anticipatory response to potential existential crises they term predictive anticipatory activity, which is similar to conscious quantum anticipation, citing anticipative entanglement swapping experiments such as Ma et al. (2002).

The tendency towards an implicitly classical view of causality is similar to that among neuroscientists, with an added belief in the irreducible nature of randomness, as opposed to a need for hidden variables supporting quantum entanglement, rejecting Einstein’s disclaimer *“God does not play dice with the universe.”* Belief in irreducible randomness means that the principal evidence for subjectivity in quanta – the idiosyncratic unpredictable nature of individual particle trajectories – is washed out in the bath water of irreducible randomness, converging to the wave amplitude on repetition, consistent with the correspondence principle, that the behaviour of systems described by the theory of quantum mechanics reproduces classical physics in the limit of large quantum numbers.

Non-IID interactions may Preserve Quantum Reality: In Born’s (1920) correspondence principle, systems described by quantum mechanics are believed to reproduce classical physics in the limit of large quantum numbers – if measurements performed on macroscopic systems have limited resolution and cannot resolve individual microscopic particles, then the results behave classically – the coarse-graining principle (Kofler & Brukner 2007). Subsequently Navascués & Wunderlich (2010) proved that in situations covered by IID (independent and identically distributed measurements) in which each run of an experiment must be repeated under exactly the same conditions and independently of other runs, we arrive at macroscopic locality. Similarly, temporal quantum correlations reduce to classical correlations and quantum contextuality reduces to macroscopic non-contextuality (Henson & Sainz 2015).

However Gallego & Dakić (2021) have shown that, surprisingly, quantum correlations survive in the macroscopic limit if correlations are not IID distributed at the level of microscopic constituents and that the entire mathematical structure of quantum theory, including the superposition principle is preserved in the limit. This macroscopic quantum behaviour allows them to show that Bell nonlocality is visible in the macroscopic limit.

Fig 76: Macroscopic Bell-Type experiment.

"The IID assumption is not natural when dealing with a large number of microscopic systems. Small quantum particles interact strongly and quantum correlations and entanglement are distributed everywhere. Given such a scenario, we revised existing calculations and were able to find complete quantum behavior at the macroscopic scale. This is completely against the correspondence principle, and the transition to classicality does not take place" (Borivoje Dakić).

"It is amazing to have quantum rules at the macroscopic scale. We just have to measure fluctuations, deviations from expected values, and we will see quantum phenomena in macroscopic systems. I believe this opens the door to new experiments and applications" (Miguel Gallego).

Their approach is described as follows:

In this respect, one important consequence of the correspondence principle is the concept of macroscopic locality (ML): Coarse-grained quantum correlations become local (in the sense of Bell) in the macroscopic limit. ML has been challenged in different circumstances, both theoretically and experimentally. However, as far as we know, nonlocality fades away under coarse graining when the number of particles N in the system goes to infinity. In a bipartite Bell-type experiment where the parties measure intensities with a resolution of the order of $N^{1/2}$ or, equivalently, $O(N^{1/2})$ coarse graining. Then, under the premise that particles are entangled only by independent and identically distributed pairs, Navascués & Wunderlich (2010) prove ML for quantum theory.

We generalize the concept of ML to any level of coarse graining $\alpha \in [0, 1]$, meaning that the intensities are measured with a resolution of the order of N^α . We drop the IID assumption, and we investigate the existence of a boundary between quantum (nonlocal) and classical (local) physics, identified by the minimum level of coarse graining α required to restore locality. To do this, we introduce the concept of macroscopic quantum behavior (MQB), demanding that the Hilbert space structure, such as the superposition principle, is preserved in the thermodynamic limit.

Conclusion: We have introduced a generalized concept of macroscopic locality at any level of coarse graining $\alpha \in [0, 1]$. We have investigated the existence of a critical value that marks the quantum-to-classical transition. We have introduced the concept of MQB at level α of coarse graining, which implies that the Hilbert space structure of quantum mechanics is preserved in the thermodynamic limit. This facilitates the study of macroscopic quantum correlations. By means of a particular MQB at $\alpha = 1/2$,

$$|W\rangle = \frac{1}{\sqrt{N}} (|100\dots 0\rangle + |010\dots 0\rangle + \dots + |000\dots 1\rangle)$$

we show that $\alpha_c \geq 1/2$, as opposed to the IID case, for which $\alpha_{IID} \leq 1/2$. An upper bound on α_c is, however, lacking in the general case. The possibility that no such transition exists remains open, and perhaps there exist systems for which ML is violated at $\alpha = 1$.

This means for example, that in (a) neural system processing, where the quantum unstable context is continually evolving as a result of edge-of-chaos processing, and so repeated IID measurements are not made and (b) biological evolution, where a sequence of unique mutations in quantum walks (Santiago-Alarcon et al. (2020)) become sequentially fixed by natural and sexual selection, which is also consciously mediated in eucaryote organisms, both inherit implicit quantum non-locality in their evolution.

Kerskens & Pérez (2022) have adapted an idea developed for experiments to prove the existence of quantum gravity, Marletto & Vedral (2017) and used it to infer that brain processes are intrinsically quantum in nature. When you take known quantum systems, which interact with an unknown system, if the known systems entangle, then the unknown must be a quantum system, too. It circumvents the difficulties to find measuring devices for something we know nothing about.

For our experiments we used proton spins of 'brain water' as the known system. 'Brain water' builds up naturally as fluid in our brains and the proton spins can be measured using MRI (Magnetic Resonance Imaging). Then, by using a specific MRI design to seek entangled spins, we found MRI signals that resemble heartbeat evoked potentials, a form of EEG signals. EEGs measure electrical brain currents, which some people may recognise from personal experience or simply from watching hospital dramas on TV.

Electrophysiological potentials like the heartbeat evoked potentials are normally not detectable with MRI and the scientists believe they could only observe them because the nuclear proton spins in the brain were entangled.

If entanglement is the only possible explanation here then that would mean that brain processes must have interacted with the nuclear spins, mediating the entanglement between the nuclear spins. As a result, we can deduce that those brain functions must be quantum. Because these brain functions were also correlated to short-term memory performance and conscious awareness, it is likely that those quantum processes are an important part of our cognitive and conscious brain functions.

This experiment was extremely challenging, and requires replication, but it suggests conscious brain processing as a whole is intrinsically quantum in nature. There are a number of quantum descriptions of conscious brain activity that invoke specific processes to invoke a link between conscious intentional activity and ongoing brain states.

The Quantum Measurement Problem May Contradict Objective Reality: In quantum theory, before collapse, the system is said to be in a superposition of two states, and this quantum state is described by the wave function, which evolves in time and space. This evolution is both deterministic and reversible: given an initial wave function, one can predict what it'll be at some future time, and one can in principle run the evolution backward to recover the prior state. Measuring the wave function, however, causes it to collapse, mathematically speaking, such that the system in our example shows up as either heads or tails. It's an irreversible, one-time-only and no one knows what defines the process or boundaries of measurement.

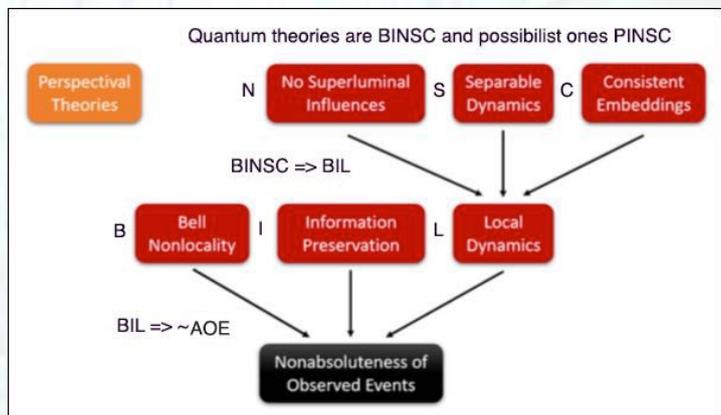

One model that preserves the absoluteness of the observed event — either heads or tails for all observers—is the GRW theory, where quantum systems exist in a superposition of states until the superposition spontaneously and randomly collapses, independent of an observer. Whatever the outcome—heads or tails in our example—it shall hold for all observers. But GRW, and the broader class of “spontaneous collapse” theories, run foul of a long-cherished physical principle: the preservation of information. By contrast, the “many worlds” interpretation of quantum mechanics allows for non-absoluteness of observed events, because the wave function branches into multiple contemporaneous realities, in which in one “world,” the system will come up heads, while in another, it'll be tails.

Ormrod, Venkatesh and Barrett (2023, Ananthaswamy 2023) focus on perspectival theories that obey three properties:

- (1) **Bell nonlocality (B).** Alice chooses her type of measurement freely and independently of Bob, and vice versa – of their own free will – an important assumption. Then, when they eventually compare notes, the duo will find that their measurement outcomes are correlated in a manner that implies the states of the two particles are inseparable: knowing the state of one tells you about the state of the other.
- (2) **The preservation of information (I).** Quantum systems that show deterministic and reversible evolution satisfy this condition. If you are wearing a green sweater today, in an information-preserving theory, it should still be possible, in principle, 10 years hence to retrieve the colour of your sweater even if no one saw you wearing it.
- (3) **Local dynamics (L).** If there exists a frame of reference in which two events appear simultaneous, then the regions of space are said to be “space-like separated.” Local dynamics implies that the transformation of a system that takes a set of input states and produces a set of output states in one of these regions cannot causally affect the transformation of a system in the other region any faster than the speed of light, and vice versa. Each subsystem undergoes its own transformation, and so does the entire system as a whole. If the dynamics are local, the transformation of the full system can be decomposed into transformations of its individual parts: the dynamics are said to be separable. In contrast, when two particles share a state that's Bell nonlocal (that is, when two particles are entangled, per quantum theory), the state is said to be inseparable into the individual states of the two particles. If transformations behaved similarly, in that the global transformation could not be described in terms of the transformations of individual subsystems, then the whole system would be dynamically inseparable.

Fig 76b: A graphical summary of the theorems. Possibilistic Bell Nonlocality is Bell Nonlocality that arises not only at the level of probabilities, but at the level of discrete possibilities.

Their work analyses how perspectival quantum theories are BINSNC, and that NSC implies L, so BINSNC is BIL. Such BIL theories are then required to handle a deceptively simple thought experiment. Imagine that Alice and Bob, each in their own lab, make a measurement on one of a pair of particles. Both Alice and Bob make one measurement each, and both do the exact same measurement. For example, they might both measure the spin of their particle in the up-down direction. Viewing Alice and Bob and their labs from the outside are Charlie and Daniela, respectively. In principle, Charlie and Daniela should be able to measure the spin of the same particles, say, in the left-right direction. In an information-preserving theory, this should be possible. Using this

scenario, the team proved that the predictions of any BIL theory for the measurement outcomes of the four observers contradict the absoluteness of observed events. This leaves physicists at an unpalatable impasse: either accept the non-absoluteness of observed events or give up one of the assumptions of a BIL theory.

Orrod says dynamical separability is “kind of an assumption of reductionism – you can explain the big stuff in terms of these little pieces.” Just like a Bell nonlocal state cannot be reduced to some constituent states, it may be that the dynamics of a system are similarly holistic, adding another kind of nonlocality to the universe. Importantly, giving it up doesn't cause a theory to fall afoul of Einstein's theories of relativity, much like physicists have argued that Bell nonlocality doesn't require superluminal or nonlocal causal influences but merely nonseparable states. Orrod, Venkatesh and Barrett note: “*Perhaps the lesson of Bell is that the states of distant particles are inextricably linked, and the lesson of the new ... theorems is that their dynamics are too.*” The assumptions used to prove the theorem don't explicitly include an assumption about freedom of choice because no one is exercising such a choice. But if a theory is Bell nonlocal, it implicitly acknowledges the free will of the experimenters.

An experimental realisation of non-absoluteness of observation has been devised (Proietti et al., 2019) as shown in fig 76c using quantum entanglement.

The experiment involves two people observing a single photon that can exist in one of two alignments, but until the moment someone actually measures it to determine which, the photon is in a superposition. A scientist analyses the photon and determines its alignment. Another scientist, unaware of the first's measurement, is able to confirm that the photon - and thus the first scientist's measurement - still exists in a quantum superposition of possible outcomes. As a result, each scientist experiences a different reality - both "true" even though they disagree with each other. In a subsequent experiment, Bong et al. (2020) transform the thought experiment into a mathematical theorem that confirms the irreconcilable contradiction at the heart of the Wigner scenario.

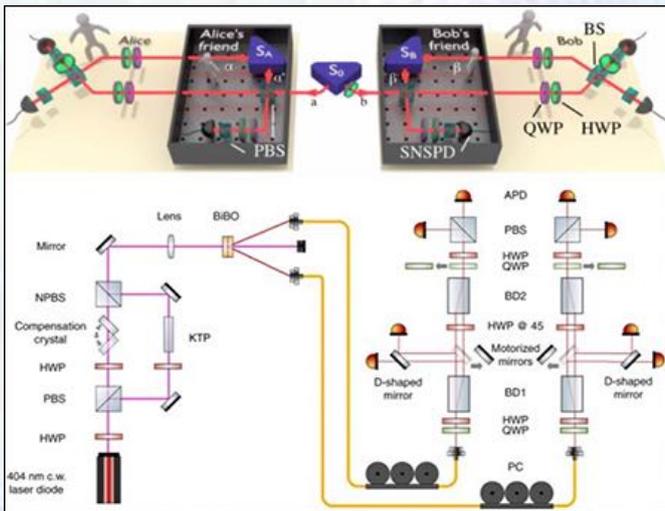

Fig 76c: Above An experimental realisation of the Wigner' friend setup showing there is no such thing as objective reality - quantum mechanics allows two observers to experience different, conflicting realities. Below the proof of principle experiment of Bong et al. (2020) demonstrating mutual inconsistency of 'No-Superdeterminism', 'Locality' and 'Absoluteness of Observed Events'.

The team also tests the theorem with an experiment, using photons as proxies for the humans, accompanied by new forms of Bell's inequalities, by building on a scenario with two separated but entangled friends. The researchers prove that if quantum evolution is controllable on the scale of an observer, then one of (a) **No-Superdeterminism** — the assumption of 'freedom of choice' used in derivations of Bell inequalities - that the experimental settings can be chosen freely — uncorrelated with any

relevant variables prior to that choice, (2) **Locality** or (3) **Absoluteness of Observed Events** — that every observed event exists absolutely, not relatively — must be false. Although the violation of Bell-type inequalities in such scenarios is not in general sufficient to demonstrate the contradiction between those three assumptions, new inequalities can be derived, in a theory-independent manner, that are violated by quantum correlations. This is demonstrated in a proof-of-principle experiment where a photon's path is deemed an observer. This new theorem places strictly stronger constraints on physical reality than Bell's theorem.

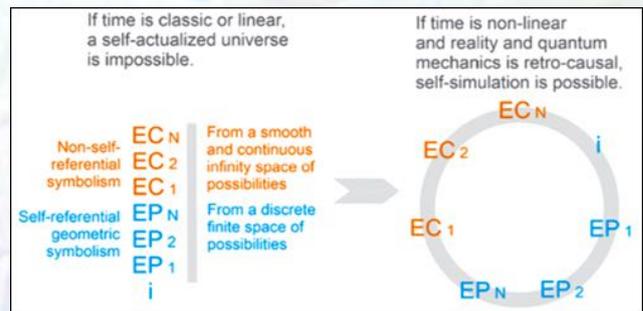

Self-Simulated Universe: Another theory put forward by gravitational theorists (Irwin, Amaral & Chester 2020) also uses retrocausality to try to explain the ultimate questions: Why is there anything here at all? What primal state of existence could have possibly birthed all that matter, energy, and time, all that everything? And the way that consciousness arose—is it some fundamental proto-state of the universe itself, or an emergent phenomenon that's purely neurochemical and material in nature?

This approach attempts to answer both questions in a way that weds aspects of Nick Bostrom’s Simulation Argument with “timeless emergentism.” termed the “panpsychism self-simulation model,” that says the physical universe may be a “strange loop” that may self-generate new sub-realities in an almost infinite hierarchy of tiers in-laid with simulated realities of conscious experience. In other words, the universe is creating itself through thought, willing itself into existence on a perpetual loop that efficiently uses all mathematics and fundamental particles at its disposal. The universe, they say, was always here (timeless emergentism) and is like one grand thought that makes mini thoughts, called “code-steps or actions”, again sort of a Matryoshka doll.

David Chester comments:

“While many scientists presume materialism to be true, we believe that quantum physics may provide hints that our reality could be a mental construct. Recent advances in quantum gravity, like seeing spacetime emergent via a hologram, is also a touch that spacetime isn’t fundamental. this can be also compatible with ancient Hermetic and Indian philosophy. In a sense, the mental construct of reality creates spacetime to efficiently understand itself by creating a network of subconscious entities that may interact and explore the totality of possibilities.”

Fig 77: Self-Simulated Universe: Humans are near the point of demarcation, where *EC* or thinking matter emerges into the choice-sphere of the infinite set of possibilities of thought, EC_{∞} . Beyond the human level, physics allows for larger and more powerful networks that are also conscious. At some stage of the simulation run, a conscious *EC* system emerges that is capable of acting as the substrate for the primitive spacetime code, its initial conditions, as mathematical thought, and simulation run, as a thought, to self-actualize itself. Linear time would not permit this logic, but non-linear time does.

They modify the *simulation hypothesis* to a *self-simulation hypothesis*, where the physical universe, as a strange loop, is a mental self-simulation that might exist as one of a broad class of possible code-theoretic quantum gravity models of reality obeying the *principle of efficient language* axiom, and discuss implications of the self-simulation hypothesis such as an informational arrow of time.

Fig 77b: This emphasis on coding is problematic, as it is trying to assert a consciousness-makes-reality loop through an apparently abstract coded representation based on discrete computation-like processes, assuming an "tit-from-bit" notion that reality is made from information, not just described by it.

The self-simulation hypothesis is built upon the following axioms:

1. **Reality, as a strange loop**, is a code-based self-simulation in the mind of a panpsychic universal consciousness that emerges from itself via the information of code-based mathematical thought or self-referential symbolism plus emergent non-self-referential thought. Accordingly, reality is made of information called thought.
2. **Non-local spacetime and particles are secondary** or emergent from this code, which is itself a pre-spacetime thought within a self-emergent mind.
3. **The panconsciousness has freewill** to choose the code and make syntactical choices. Emergent lower levels of consciousness also make choices through observation that influence the code syntax choices of the panconsciousness.
4. **Principle of efficient language** (Irwin 2019) The desire or decision of the panconscious reality is to generate as much meaning or information as possible for a minimal number of primitive thoughts, i.e., syntactical choices, which are mathematical operations at the pre-spacetime code level.

It from bit: Otherwise put, every it — every particle, every field of force, even the space-time continuum itself — derives its function, its meaning, its very existence entirely — even if in some contexts indirectly — from the apparatus-elicited answers to yes-or-no questions, binary choices, bits. It from bit symbolizes the idea that every item of the physical world has at bottom — at a very deep bottom, in most instances — an immaterial source and explanation; that which we call reality arises in the last analysis from the posing of yes-no questions and the registering of equipment-evoked responses; in short, that all things physical are information-theoretic in origin and that this is a **participatory universe** (Wheeler 1990).

John Eccles (1986) proposed a quantum theory involving psychon quasi-particles mediating uncertainty of synaptic transmission to complementary dendrons cylindrical bundles of neurons arranged vertically in the six outer layers or laminae of the cortex. Eccles proposed that each of the 40 million dendrons is linked with a mental unit, or “*psychon*”, representing a unitary conscious experience. In willed actions and thought, psychons act on dendrons and, for a

moment, increase the probability of the firing of selected neurons through quantum tunnelling effect in synaptic exocytosis, while in perception the reverse process takes place. This model has been elaborated by a number of researchers (Eccles 1990, 1994, Beck & Eccles 1992, Georgiev 2002, Hari 2008). The difficulty with the theory is that the psychons are then physical quasi-particles with integrative mental properties. So it's a quasi-physical description that doesn't manifest subjectivity except by its integrative physical properties. In the last chapter of his book *The Neurophysiological Basis of Mind* (1953), Eccles not only hypothesized the existence of a "self-conscious mind" relatively independent of the cerebral structures, but also supposed that a very weak influence of will on a few neurons of the cerebral cortex could cause remarkable changes in brain activity leading to the notion of volition being a form of "psychokinesis" (Giroladini 1991), supported also by Wilder Penfield (1960).

Schwartz, Stapp & Beauregard (2005) advance a quantum theory of conscious volition, in which attentive will can influence physical brain states using quantum principles, in particular von Neumann's process 1 or collapse of the wave function, complementing process 2, the causal evolution of the Schrödinger wave function. They cite specific cognitive processes leading the physical changes in the manner of ongoing brain function:

There is at least one type of information processing and manipulation that does not readily lend itself to explanations that assume that all final causes are subsumed within brain, or more generally, central nervous system mechanisms. The cases in question are those in which the conscious act of wilfully altering the mode by which experiential information is processed itself changes, in systematic ways, the cerebral mechanisms used. There is a growing recognition of the theoretical importance of applying experimental paradigms that use directed mental effort to produce systematic and predictable changes in brain function. ... Furthermore, an accelerating number of studies in the neuroimaging literature significantly support the thesis that, with appropriate training and effort, people can systematically alter neural circuitry associated with a variety of mental and physical states.

They point out that it is necessary in principle to advance to the quantum level to achieve an adequate theory of the neurophysiology of volitionally directed activity. The reason, essentially, is that classic physics is an approximation to the more accurate quantum theory, and that this classic approximation eliminates the causal efficacy of our conscious efforts that these experiments empirically manifest.

They explain how structural features of ion conductance channels critical to synaptic function entail that the classical approximation to quantum reality fails in principle to cover the dynamics of a human brain, so that quantum dynamics must be used. The principles of quantum theory must then link the quantum physical description of the subject's brain to their stream of conscious experiences. The conscious choices by human agents thereby become injected non-trivially into the causal interpretation of neuroscience and neuropsychology experiments, through type 1 processes performing quantum measurement operations. This particularly applies to those experimental paradigms in which human subjects are required to perform decision-making or attention-focusing tasks that require conscious effort.

Conscious effort itself can, justifiably within science, be taken to be a primary variable whose complete causal origins may be untraceable in principle, but whose causal efficacy in the physical world can be explained on the basis of the laws of physics.

The mental act of clear-minded introspection and observation, variously known as mindfulness, mindful awareness, bare attention, the impartial spectator, etc., is a well-described psychological phenomenon with a long and distinguished history in the description of human mental states. ... In the conceived approach, the role played by the mind, when one is observing and modulating one's own emotional states, is an intrinsically active and physically efficacious process in which mental action is affecting brain activity in a way concordant with the laws of physics.

They propose a neurobiological interpretation where calcium channels play a pivotal role in type 1 processes at the synaptic level:

At their narrowest points, calcium ion channels are less than a nanometre in diameter. This extreme smallness of the opening in the calcium ion channels has profound quantum mechanical implications. The narrowness of the channel restricts the lateral spatial dimension. Consequently, the lateral velocity is forced by the quantum uncertainty principle to become large. This causes the quantum cloud of possibilities associated with the calcium ion to fan out over an increasing area as it moves away from the tiny channel to the target region where the ion will be absorbed as a whole, or not absorbed at all, on some small triggering site. ... This spreading of this ion wave packet means that the ion may or may not be absorbed on the small triggering site. Accordingly, the contents of the vesicle may or may not be released. Consequently, the quantum state of the brain has a part in which the neurotransmitter is released and a part in which the neurotransmitter is not released. This quantum splitting occurs at every one of the trillions of nerve terminals. ... In fact, because of uncertainties on timings and locations, what is generated by the physical processes in the brain will be not a single discrete set of non-overlapping physical possibilities but rather a huge smear of classically conceived possibilities. Once the physical state of the brain has evolved into this huge smear of possibilities one must appeal to the

quantum rules, and in particular to the effects of process 1, in order to connect the physically described world to the streams of consciousness of the observer/participants.

However, they note that this focus on the motions of calcium ions in nerve terminals is not meant to suggest that this particular effect is the only place where quantum effects enter into the brain process, or that the quantum process 1 acts locally at these sites. What is needed here is only the existence of some large quantum of effect.

A type 1 process beyond the local deterministic process 2 is required to pick out one experienced course of physical events from the smeared-out mass of possibilities generated by all of the alternative possible combinations of vesicle releases at all of the trillions of nerve terminals. This process brings in a choice that is not determined by any currently known law of nature, yet has a definite effect upon the brain of the chooser.

They single out the quantum zeno effect, in which rapid multiple measurements can act to freeze a quantum state and delay its evolution and cite James (1892 417): The essential achievement of the will, in short, when it is most 'voluntary,' is to attend to a difficult object and hold it fast before the mind. Effort of attention is thus the essential phenomenon of will. ... Consent to the idea's undivided presence, this is effort's sole achievement. Everywhere, then, the function of effort is the same: to keep affirming and adopting the thought which, if left to itself, would slip away." This coincides with the studies already cited on wilful control of the emotions to imply evidence of effect.

Much of the work on attention since James is summarized and analysed in Pashler (1998). He emphasizes that the empirical 'findings of attention studies argue for a distinction between perceptual attentional limitations and more central limitations involved in thought and the planning of action. A striking difference that emerges from the experimental analysis is that the perceptual processes proceed essentially in parallel, whereas the post-perceptual processes of planning and executing actions form a single queue, is in line with the distinction between 'passive' and 'active' processes. A passive stream of essentially isolated process 1 events versus active processes involving effort-induced rapid sequences of process 1 events that can saturate a given capacity.

There is in principle, in the quantum model, an essential dynamic difference between the unconscious processing done by the Schrödinger evolution, which generates by a local process an expanding collection of classically conceivable experiential possibilities and the process associated with the sequence of conscious events that constitute the wilful selection of action. The former are not limited by the queuing effect, because process 2 simply develops all of the possibilities in parallel. Nor is the stream of essentially isolated passive process 1 events thus limited. It is the closely packed active process 1 events that can, in the von Neumann formulation, be limited by the queuing effect.

This quantum model accommodates naturally all of the complex structural features of the empirical data that he describes. Chapter 6 emphasizes a specific finding: strong empirical evidence for what he calls a central processing bottleneck associated with the attentive selection of a motor action. This kind of bottleneck is what the quantum-physics-based theory predicts: the bottleneck is precisely the single linear sequence of mind-brain quantum events that von Neumann quantum theory describes.

Hameroff and Penrose (2014, Hameroff 2022) have also proposed a controversial theory that consciousness originates at the quantum level inside neurons, rather than the conventional view that it is a product of connections between neurons, coupling orchestrated objective reduction (OOR) to hypothetical quantum cellular automata in the microtubules of neurons. The theory is regarded as implausible by critics, both physicists and neuroscientists, who consider it to be a poor model of brain physiology on multiple grounds. Orchestration refers to the hypothetical process by which microtubule-associated proteins, influence or orchestrate qubit state reduction by modifying the spacetime-separation of their superimposed states. The latter is based on Penrose's objective-collapse theory for interpreting quantum mechanics. Derakhshani et al. (2022) discount gravitational collapse theory experimentally:

We perform a critical analysis of the Orch OR consciousness theory at the crossroad with the newest experimental results coming from the search for spontaneous radiation predicted by the simplest version of gravity-related dynamical collapse models. We conclude that Orch OR theory, when based on the simplest version of gravity-related dynamical collapse [Diósi 2019, Penrose 1996, 2014a,b], is highly implausible in all the cases analyzed.

The tubulin protein dimers of the microtubules have hydrophobic pockets that may contain delocalised π electrons. Hameroff claims that this is close enough for the tubulin π electrons to become quantum entangled. This would leave these quantum computations isolated inside neurons. Hameroff then proposed, although this idea was rejected by Reimers (2009), that coherent Frolich condensates in microtubules in one neuron can link with microtubule condensates in other neurons and glial cells via the gap junctions of electrical synapses claiming these are sufficiently small for quantum tunnelling across, allowing them to extend across a large area of the brain. He further postulated that the action of this large-scale quantum activity is the source of 40 Hz gamma waves, building upon the theory that

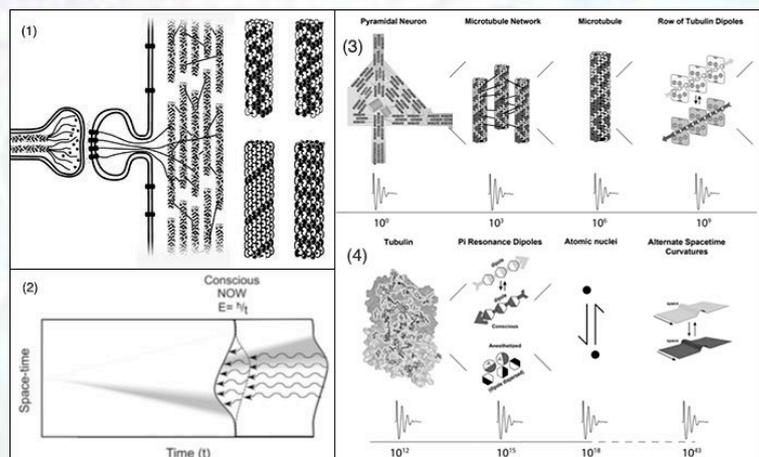

gap junctions are related to the gamma oscillation. Craddock et. al. (2017) make claims about anaesthetics based on the exclusive action of halothane types on microtubules, which focus on halothane type molecules lack consistency with the known receptor-based effects of ketamine and N₂O on NMDA receptors, also shared by halothanes and that of propofol on GABA receptors. Evidence for anaesthetic disruption of microtubules, Kelz & Mashour's (2019) review, applies indiscriminately to all anaesthetics, from halothane to ketamine widely across the tree of life, from paramecium to humans, including both synaptic and ion-channel effects, indicating merely that microtubular integrity is necessary for consciousness and does not indicate microtubules have a key role in consciousness itself, other than their essential architectural and transport roles.

Because of its dependence on Penrose's idea of gravitational quantum collapse, the theory is confined to objective reduction, at face value crippling the role of free-will in conscious experience. However Hameroff (2012) attempts to skirt this by applying notions of retro-causality, as illustrated in fig 77(2), in which a dual-time approach (King 1989) is used to invoke a quantum of the present, the Conscious NOW. We will see that retrocausality is a process widely cited also in this work. Hameroff justifies such retrocausality from three sources. Firstly he cites an open brain experiment of Libet. Peripheral stimulus, e.g., of the skin of the hand, resulted in an "EP" spike in the somatosensory cortical area for the hand ~30ms after skin contact, consistent with the time required for a neuronal signal to travel from hand to spinal cord, thalamus, and brain. The stimulus also caused several 100 ms of ongoing cortical activity following the EP. Subjects reported conscious experience of the stimulus (using Libet's rapidly moving clock) near-immediately, e.g., at the time of the EP at 30ms, hinting at retro-causality of the delayed "readiness potential".

Secondly, he cites a number of well-controlled studies using electrodermal activity, fMRI and other methods to look for emotional responses, e.g., to viewing images presented at random times on a computer screen. Surprisingly, the changes occurred half a second to two seconds before the images appeared. They termed the effect pre-sentiment because the subjects were not consciously aware of the emotional feelings. Non-conscious emotional sentiment (i.e., feelings) appeared to be referred backward in time. Bem (2012, 2016) reported on studies showing statistically significant backward time effects, most involving non-conscious influence of future emotional effects (e.g., erotic or threatening stimuli) on cognitive choices. Studies by others have reported both replication, and failure to replicate, the controversial results. Thirdly he cites a number of delayed choice experiments widely discussed in this work.

Sahu S, et al. (2013) found that electronic conductance along microtubules, normally extremely good insulators, becomes exceedingly high, approaching quantum conductance, at certain specific resonance frequencies of applied alternating current (AC) stimulation. These resonances occur in gigahertz, megahertz and kilohertz ranges, and are particularly prominent in low megahertz (e.g. 8.9 MHz). Hameroff & Penrose (2014) suggest that EEG rhythms (brain waves) also derive from deeper level microtubule vibrations.

Fig 77c: (1) An axon terminal releases neurotransmitters through a synapse and are received by microtubules in a neuron's dendritic spine. (2) A superposition develops over time, e.g., a particle separating from itself, shown as simultaneous curvatures in opposite directions. The magnitude of the separation is related to E , the gravitational self-energy. At a particular time t , E reaches threshold by $E = h\bar{v}/t$, and spontaneous OR occurs, one particular curvature is selected. This OR event is accompanied by a moment of conscious experience ("NOW"), its intensity proportional to E . Each OR event also results in temporal non-locality, referring quantum information backward in classical time (curved arrows). (3,4) Scale dependent resonances from the pyramidal neuron, through microtubules, to π -orbitals and gravitational effects.

However none of these Hameroff-Penrose quantum processes have been empirically verified and the complex tunnelling invoked is far from being a plausible neurophysiological process. The model requires that the quantum state of the brain has macroscopic quantum coherence, which needs to be maintained for around a tenth of a second. But, according to calculations made by Max Tegmark (2000), this property ought not to hold for more than about 10^{-13} s. Hameroff and co-workers (Hagen et al. 2002) have advanced reasons why this number should actually be of the order

of a tenth of a second. But 12 orders of magnitude is a very big difference to explain away and serious doubts remain about whether the Penrose–Hameroff theory is technically viable.

Two experiments (Lewton 2022, Tangerman 2022), presented at The Tucson Science of Consciousness conference merely showed that anaesthetics hastened delayed luminescence and that under laser excitation prolonged excitation diffused through microtubules further than expected when not under anaesthetics. There is no direct evidence for the cellular automata proposed and microtubules are critically involved in neuronal architecture, and are also involved in molecular transport, so functional conflict would result from adding another competing function. Hameroff (2022) cites processes, from the pyramidal neuron, down through microtubules, to π -orbital resonances and gravitational space-time effects, but the linkage to microtubules is weak.

OOR would force collapse, but it remains unestablished how conscious volition is invoked, because collapse is occurring objectively in terms of Penrose’s notion of space-time blisters. It remains unclear how these hypothetical objective or “platonic” entities, as Penrose puts it, relate to subjective consciousness or volition. Hameroff (2012) in “How quantum brain biology can rescue conscious free will” attempts an explanation, but this simply comes down to objective OOR control:

Orch OR directly addresses conscious causal agency. Each reduction/conscious moment selects particular microtubule states which regulate neuronal firings, and thus control conscious behavior. Regarding consciousness occurring “too late,” quantum state reductions seem to involve temporal non-locality, able to refer quantum information both forward and backward in what we perceive as time, enabling real-time conscious causal action. Quantum brain biology and Orch OR can thus rescue free will.

For this reason Symbiotic Existential Cosmology remains agnostic about such attempts to invoke unestablished, exotic quantum effects, and instead points to the non-IID nature of brain processes generally, meaning that neurodynamics is a fractal quantum process not required to be adiabatically isolated, as decoherence limits of technological quantum computing suggest.

QBism and the Conscious Consensus Quantum Reality

QBism (von Bayer 2016) is an acronym for “quantum Bayesianism” a founding idea from which it has since moved on. It is a version of quantum physics founded on the conscious expectations of each physicist and their relationships with other physicists. According to QBism, experimental measurements of quantum phenomena do not quantify some feature of an independently existing natural structure. Instead, they are actions that produce experiences in the person or people doing the measurement.

“When I take an action on the world, something genuinely new comes out.”

This is very similar to the way Symbiotic Existential Cosmology presents **consciousness as primary**, in the sense that we all experience subjective consciousness and infer the real world through the consensus view between conscious observers of our experiences of what we come to call the physical world. So although we know the physical world is necessary for our biological survival – **the universe is necessary**, we derive our knowledge of it exclusively and only through our conscious experiences of it.

The focus is on how to gain knowledge in a probabilistic universe... In this probabilistic interpretation, collapse of the quantum wave function has little to do with the object observed/measured. Rather, the crux of the matter is change in the knowledge of the observer based on new information acquired through the process of observing. Klaus Fuchs explains: “When a quantum state collapses, it’s not because anything is happening physically, it’s simply because this little piece of the world called a person has come across some knowledge, and he updates his knowledge... So the quantum state that’s being changed is just the person’s knowledge of the world, it’s not something existent in the world in and of itself.”

QBism is agnostic about whether there is a world that is structured independently of human thinking. It doesn’t assume we are measuring pre-existing structures, but nor does it pretend that quantum formalism is just a tool. Each measurement is a new event that guides us in formulating more accurate rules for what we will experience in future events. These rules are not just subjective, for they are openly discussed, compared and evaluated by other physicists. QBism therefore sees physicists as permanently connected with the world they are investigating. Physics, to them, is an open-ended exploration that proceeds by generating ever new laboratory experiences that lead to ever more successful, but revisable, expectations of what will be encountered in the future. In QBism the wave function is no longer an aspect of physical reality as such, but a feature of how the observer’s expectations will be changed by an act of quantum measurement.

The principal thesis of QBism is simply this: quantum probabilities are numerical measures of personal degrees of belief. According to QBism, experimental measurements of quantum phenomena do not quantify some feature of an independently existing natural structure. Instead, they are actions that produce experiences in the person or people doing the measurement. In the conventional version of quantum theory, the immediate cause of the collapse is left entirely unexplained, or "miraculous" although sometimes assumed to be essentially random. QBism solves the problem as follows. In any experiment the calculated wave function furnishes the prior probabilities for empirical observations that may be made later. Once an observation has been made new information becomes available to the agent performing the experiment. With this information the agent updates their probability and their wave function, instantaneously and without magic.

So in the Wigner's friend experiment, the friend reads the counter while Wigner, with his back turned to the apparatus, waits until he knows that the experiment is over. The friend learns that the wave function has collapsed to the up outcome. Wigner, on the other hand, knows that a measurement has taken place but doesn't know its result. The wave function he assigns is a superposition of two possible outcomes, as before, but he now associates each with a definite reading of the counter and with his friend's knowledge of that reading — a knowledge that Wigner does not share. For the QBist there is no problem: Wigner and his friend are both right. Each assigns a wave function reflecting the information available to them, and since their respective compilations of information differ, their wave functions differ too. As soon as Wigner looks at the counter himself or hears the result from his friend, he updates his wave function with the new information, and the two will agree once more—on a collapsed wave function.

According to the conventional interpretation of quantum mechanics, in the Schrödinger's cat experiment, the value of a superimposed wave function is a blend of two states, not one or the other. What is the state of the cat after one half-life of the atom, provided you have not opened the box? The fates of the cat and the atom are intimately entangled. An intact atom implies a living cat; a decayed atom implies a dead cat. It seems to follow that since the atom's wave function is unquestionably in a superposition so is the cat: it is both alive and dead. As soon as you open the box, the paradox evaporates: the cat is either alive or dead. But while the box is still closed — what are we to make of the weird claim that the cat is dead and alive at the same time? According to QBism, the state of an unobserved atom, or a cat, has no value at all. It merely represents an abstract mathematical formula that gives the odds for a future observation: 0 or 1, intact or decayed, dead or alive. Claiming that the cat is dead and alive is as senseless as claiming that the outcome of a coin toss is both heads and tails while the coin is still tumbling through the air. Probability theory summarises the state of the spinning coin by assigning a probability of $1/2$ that it will be heads. So QBism refuses to describe the cat's condition before the box is opened and thus rescues it from hovering in a limbo of living death.

If the wave-function, as QBism maintains, says nothing about an atom or any other quantum mechanical object except for the odds for future experimental outcomes, the unperformed experiment of looking in the box before it is opened has no result at all, not even a speculative one. The bottom line: According to the QBist interpretation, the entangled wave-function of the atom and the cat does not imply that the cat is alive and dead. Instead, it tells an agent what she can reasonably expect to find when they open the box. This makes QBism compatible with phenomenologists, for whom experience is always "intentional" — i.e. directed towards something — and these intentionalities can be fulfilled or unfulfilled. Phenomenologists ask questions such as: what kind of experience is laboratory experience? How does laboratory experience — in which physicists are trained to see instruments and measurements in a certain way — differ from, say, emotional or social or physical experiences? And how do lab experiences allow us to formulate rules that anticipate future lab experiences?

Another overlap between QBism and phenomenology concerns the nature of experiments. Experiments are performances. They're events that we conceive, arrange, produce, set in motion and witness, yet we can't make them show us anything we wish. That doesn't mean there is a deeper reality "out there" — just as, with Shakespeare, there is no "deep Hamlet" of which all other Hamlets we produce are imitations. In physics as in drama, the truth is in performance. However, there is one devastating caveat. It reduces Process 1 to simple probabilities and preempts any interaction between consciousness and wave function collapse. We simply don't know any way consciousness itself can be associated with collapsed probabilities. If it is steeped in the spooky world of entanglement, reducing the entirety of physics to collapsed probabilities may not represent in any way the degree to which conscious experiences correspond to unstable brain states at the edge of chaos making phase coherence measurements analogous to or homologous with quantum measurements may mean this picture is more complicated than meets the QBist's eye.

The Born Probability Interpretation and the Notion of Quantum “Randomness”

The Born rule provides a link between the mathematical formalism of quantum theory and experiment, and as such is almost single-handedly responsible for practically all predictions of quantum physics (Landsman 2008). The rule projects the superimposed vector $|\phi\rangle$ with a basis of eigenvectors in an inner product space onto the eigenvector of one of its eigenvalues λ_i , as a purely algebraic operation.

It states that if an observable corresponding to a self-adjoint operator A with discrete spectrum is measured in a system with normalised wave function $|\phi\rangle$ then:

- (1) the measured result will be one of the eigenvalues λ_i of A , and
- (2) the probability of measuring a given eigenvalue λ_i will equal $\langle\phi|P_i|\phi\rangle$, where P_i is the projection onto the eigenspace of A corresponding to λ_i .

Equivalently, the probability can be written as $\langle\lambda_i|\phi\rangle \cdot \overline{\langle\lambda_i|\phi\rangle} = |\langle\lambda_i|\phi\rangle|^2$.

Born's rule for calculating probabilities was really just an intuitive guess by the German physicist Max Born. So was Schrödinger's equation itself. Neither was supported by rigorous derivation. It is simply a probability law on the Hilbert space representation (Griffiths 2014) and says nothing about whether quantum uncertainty is purely random or whether there is a hidden variable theory governing it. Broadly speaking the rule is postulated, as derived above, and not proven experimentally, but assumed theoretically in experimental work:

It's not clear what exactly is meant by an experimental verification of the Born rule - the Born rule says how the quantum state relates to the probability of measurement, but "the quantum state" itself is a construct of the quantum theory that is rarely, if ever, experimentally accessible other than running repeated tests and inferring which state it was from the results assuming the Born rule is valid.

This is because we start initially with a Schrödinger wave equation as a Hamiltonian energy operator

$E|\phi\rangle = H(|\phi\rangle) = i\hbar \frac{\partial}{\partial t} |\phi\rangle$, but the wave function is experimentally inaccessible to classical observation, so we have to use the Born probability interpretation to get a particle probability we can sample e.g. in the pattern of photons on the photographic plate in the two-slit interference experiment in fig 71(f).

There are obvious partial demonstrations, but these just lead to averages that statistically approach the Probability interpretation, but don't tell us anything about the underlying process which generates these indeterminacies.

Born's rule has been verified experimentally numerous times. However, only the overall averages have been verified. For example if the prediction is 60% probability, then over large number of trials, the average outcome will approach the predicted value of 60%. This has been verified by measuring particle spin at angle A relative to the angle of its previously known spin angle. The prediction is square of $\cos(A/2)$. These predictions have also been verified with entangled pairs (Bell's state) where the same spin prediction is square of $\sin(A/2)$. What has not been verified is whether the outcomes are due to independent probability, or they are guided by some balancing mechanism.

Landsman (2008) confirms this picture:

The pragmatic attitude taken by most physicists is that measurements are what experimentalists perform in the laboratory and that probability is given the frequency interpretation (which is neutral with respect to the issue whether the probabilities are fundamental or due to ignorance). Given that firstly the notion of a quantum measurement is quite subtle and hard to define, and that secondly the frequency interpretation is held in rather low regard in the philosophy of probability, it is amazing how successful this attitude has been!

Heisenberg (1958), notes that, in the Copenhagen interpretation, probabilities arise because we look at the quantum world through classical glasses:

One may call these uncertainties [i.e. the Born probabilities] objective, in that they are simply a consequence of the fact that we describe the experiment in terms of classical physics; they do not depend in detail on the observer. One may call them subjective, in that they reflect our incomplete knowledge of the world.

Landsman (2008) clarifies:

In other words, one cannot say that the Born probabilities are either subjective (Bayesian, or due to ignorance) or objective (fundamentally ingrained in nature and independent of the observer). Instead, the situation is more subtle and has no counterpart in

classical physics or probability theory: the choice of a particular classical description is subjective, but once it has been made the ensuing probabilities are objective and the particular outcome of an experiment compatible with the chosen classical context is unpredictable. Or so Bohr and Heisenberg say. ... In most interpretations of quantum mechanics, some version of the Born rule is simply postulated.

Roger Penrose (foreword vi in Wupuluri & Doria 2018) notes:

Current quantum mechanics, in the way that it is used, is not a deterministic scheme, and probabilistic behaviour is taken to be an essential feature of its workings. Some would contend that such indeterminism is here to stay, whereas others argue that there must be underlying 'hidden variables' which may someday restore a fully deterministic underlying ontology. ... Personally, I do not insist on taking a stand on this issue, but I do not think it likely that pure randomness can be the answer. I feel that there must be something more subtle underlying it all.

John von Neumann (1951) is highly critical of both physical and algorithmic sources of randomness:

We see then that we could build a physical instrument to feed random digits directly into a high-speed computing machine and could have the control call for these numbers as needed. The real objection to this procedure is the practical need for checking computations. If we suspect that a calculation is wrong, almost any reasonable check involves repeating something done before. At that point the introduction of new random numbers would be intolerable. I think that the direct use of a physical supply of random digits is absolutely unacceptable for this reason and for this reason alone. ... Anyone who considers arithmetical methods of producing random digits is, of course, in a state of sin. For, as has been pointed out several times, there is no such thing as a random number – there are only methods to produce random numbers, and a strict arithmetic procedure of course is not such a method.

Ruth Kastner (2013) claims that the transactional interpretation is unique in giving a physical explanation for the Born rule. Zurek (2005) has made a derivation from entanglement and Sebens and Carroll have done so for an Everett perspective, although this is not strictly meaningful, since every branch of the multiverse is explored.

Because wave interference is measured through particle absorption, experiments have been made (Sinha et al. 2010) to eliminate higher-order processes which might violate the two signal interference implied by the Born interpretation because Born's rule predicts that quantum interference, as shown by a double-slit diffraction experiment, occurs from pairs of paths. Therefore using a three slit apparatus and sampling all combinations of slits we can confirm additive two wave interference, so Born applies.

Other experiments and theories attempt to derive the Born interpretation from more basic quantum properties. Masanes, Galley & Müller (2019) show Born's rule and the post-measurement state-update, can be deduced from the other quantum postulates, referred to as unitary quantum mechanics, and the assumption that ensembles on finite-dimensional Hilbert spaces are characterised by finitely many parameters. Others such as Cabelo (2018) use graph theory. The movement to regenerate the whole of quantum theory from more basic axioms e.g. of information, or probability itself is called quantum reconstruction, of which Qbism is an example (Ball 2017).

Zurek (1991, 2003, 2005) has introduced the notions of decoherence, quantum Darwinism and enviance – environment – assisted invariance, to explain the transition from quantum reality to the classical. Decoherence is the way third-party quanta disrupt the off-diagonal wave amplitudes of entanglement resulting in projection onto the "observed" classical states through exponential damping as in fig 71c. Quantum Darwinism enriches this picture by developing the notion that some quantum "pointer" states can be more robust to decoherence by replicating their information into the environment. Enviance describes this process in terms of quantum measurement, in which the environment becomes entangled with the apparatus of ideal von Neumann measurement, again promoting the transition to the classical. While these do not deal with the question of hidden variable theories versus randomness of uncertainty they have been claimed to derive the Born probabilities (Zurek 2005, Harris et al 2016) through multiple environmental interactions, illustrated by Laplace playing card probabilities in fig 77d. However all the approaches to independent derivation of the Born rule including enviance have been criticised as being logically circular (Schlosshauer & Fine 2005, Landsman 2008).

Illustrating the difficulty of the problem, John Wheeler in 1983 proposed that statistical regularities in the physical world might emerge from such a situation, as they sometimes do from unplanned crowd behaviour (Ball 2019):

"Everything is built higgledy-piggledy on the unpredictable outcomes of billions upon billions of elementary quantum phenomena", Wheeler wrote. But there might be no fundamental law governing those phenomena — indeed, he argued, that was the only scenario in which we could hope to find a self-contained physical explanation, because otherwise we're left with an infinite regression in which any fundamental equation governing behavior needs to be accounted for by some even more fundamental

principle. "In contrast to the view that the universe is a machine governed by some magic equation, ... the world is a self-synthesizing system," Wheeler argued. He called this emergence of the lawlike behavior of physics "law without law."

However the probability interpretation leads to the incorrect notion that quantum reality is somehow just a random process. Common opinions of processes like radioactive decay are treated as random by default, simply because they are indeterminate and don't obey a fixed law. Study smarter, for example, states:

Radioactive decay is a random process, meaning it is impossible to predict when an atom will emit radiation. By the random nature of radioactive decay, we mean that for every atom, there are known probabilities that they will emit radiation (and thus decay radioactively) in the next second. Still, the fact that all we have is a probability makes this a random process. We can never determine ahead of time if an atom will decay in the next second or not. This is just like throwing a (fair, cubic) dice every second.

In effect, this is equating the quantum tunnelling of individual atoms to a dice throw, which is a chaotic classical process with geometric constraints, so it is equating quantum uncertainty with classical chaotic butterfly effect systems which might also have a quantum sensitivity.

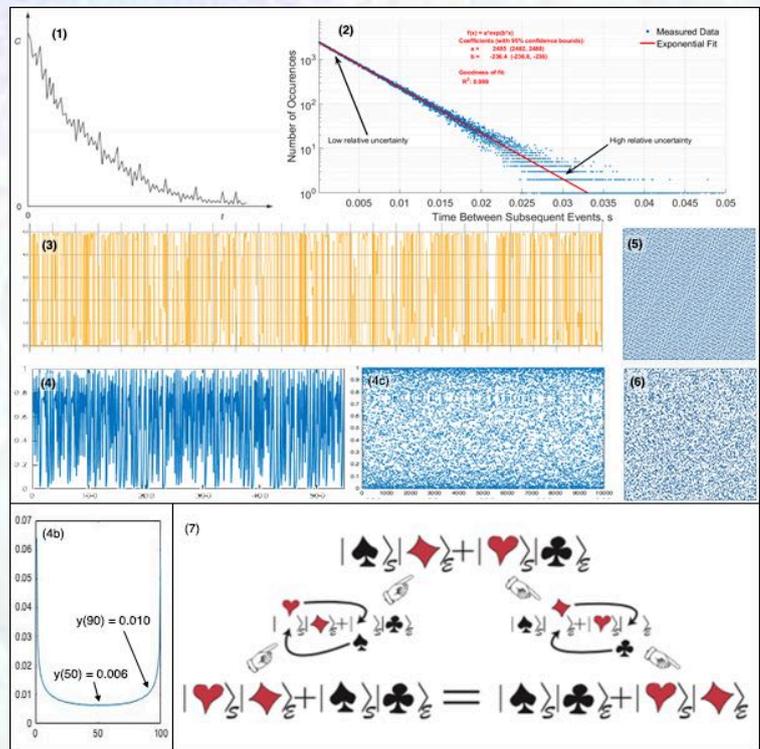

Santha & Vazirani (1986) note:

Unfortunately, the available physical sources of randomness (including zener diodes and geiger counters) are imperfect. Their output bits are not only biased but also correlated.

Geiger counters measure quantum tunnelling in individual radioactive nuclei that reflect quantum uncertainty but are emitted very slowly over long periods, so the process is not random but one of erratic exponential decay over time. Zener diodes at high voltage undergo avalanche breakdown, which is a solid state feature that lets through a flood of electrons with a fixed relaxation time, so again it is not directly measuring uncertainty, but its compounded effects.

This is remarkably similar to chaotic molecular systems displaying a butterfly effect. Very simple algorithmic chaotic systems such as the logistic iteration, where x_1 is chosen on (0,1) as a seed and the sequence is generated by $x_{n+1} = r \cdot x_n \cdot (1 - x_n)$, modelling rabbit reproduction in a finite pasture (May 1976), where the chaotic phase is ergodic and asymptotic to an interval-filling stochastic process, when $r = 4$. This is shown in fig 77d, where this iteration generates an asymptotic frequency distribution, which has been normalised over its integral to produce a probability function playing the same role as as the squared wave function to give a probability interpretation parallel to the Born rule for an elementary deterministic discrete iteration, confirming the Born rule does not in any way imply that the basis of quantum uncertainty lies in randomness.

Fig 77d: (1,2) Exponential decay of erratic radioactivity as the population of radioactive atoms becomes depleted. (3) Zener diode avalanche output. (4) Graph of the chaotic logistic iteration displaying interval-filling ergodicity in the frequency graph (4b), point plot 4(c). One can make a Born interpretation of this as a pseudo-wave function showing the relative probabilities of finding an iteration point at 0.5 and 0.9 by normalising the function over its integral, yet the process is deterministic. Therefore a probability interpretation does not imply randomness. (5,6) Quasi-random and pseudo-random or random 2-D distributions. (7) Sketch derivation of the Born formula derivation using Laplace probabilities of concealed and revealed playing cards (Zurek 2005).

The point distribution (4c) shows us closer detail that confirms this deterministic dynamical process displays pseudo-random features akin to (6), modulated by the overall probability distribution (4b), but there is a subtle anomaly in (4c) in the horizontal strip neighbouring $y = 0.75$. This does not appear in the probability distribution, which is asymptotically smooth for large n . The reason is that the

iteration has two fixed point solutions to $x = f(x)$: 0 a point attractor, and 0.75 a chaotic repelling point. There are 2^{n+1} periodic points of period n , so in a classical chaotic iteration the unstable periodic points are dense, but these have measure zero, as a countable subset of $[0, 1]$, so their probability of occurrence is zero, but their neighbouring points can be seen in (4c) as stationary butterfly effect exponential trajectories neighbouring the fixed point. None of this can happen in a quantum system and this detail is not accessible in the quantum situation either, because we have recourse only to the Born rule, so the interference experiment reflects only what we see in (4b) – the macroscopic experimental arrangement, as a statistical particle approximation to the wave power, not the underlying process governing the individual outcomes. In [fig 57](#), we see that the classical chaotic stadium billiard (1), becomes scarred by such repelling periodic orbits in the quantum situation, although open quantum systems like the quantum kicked top (2) become entangled.

Algorithmic processes approximating randomness for experimental purposes are classified as either pseudo-random, or quasi-random. **Pseudo-random** numbers more closely simulate randomness, as in the pseudorandom number generator (PRNG), or deterministic random bit generator (DRBG) used in computational random functions. An example pseudo-random number generator is $A_{n+1} = (Z * A_n + I) \bmod M$ where A_n is the previous pseudo number generated, Z is a constant multiplier, I is a constant increment, and M is a constant modulus. **Quasi-random** processes, also called low-discrepancy sequences, approach an even distribution more rapidly, but less faithfully than true randomness, because they lack larger improbable fluctuations. They are generated by a number of [algorithms](#) including Fauré, Halton and Sobol, each of which have short arithmetic computational procedures.

This leaves us in a position where the assumption of quantum randomness remains unestablished and in which a complex many-body non-local interaction, given the vast number of particles in the universe, could approximate the Born interpretation to the limits of any experimental error.

Summarising the interplay between the notion of “random” probabilistic wave function collapse and hidden variable theories, Symbiotic Existential Cosmology favours the latter on the basis that:

(1) The verification of [Bell entanglement](#) was a confirmation of the EPR claim and Einstein’s quote:

God does not play dice with the universe.

(2) The transcausal view of [quantum transactions](#) being a complex underlying hidden variable process, which is also shared by (3) [superdeterminism](#) violating statistical independence, and involving additional non-local processes (4) [non-IID processes](#) in biology not converging to the classical and (5) theories in which quantum measurement may [contradict objective reality](#) through process entanglements extending beyond Bell state entanglements.

The intrinsic difficulty that all such theories since the Bohm’s pilot wave formulation face, is that expectations are for a master equation like Schrödinger’s, when any system is likely to be a vastly complex non-local many-body problem. This criticism of the assumption of randomness applies equally to molecular dynamics, mutational evolution and neurodynamics.

The Neuroscience Perspective

Complementing this description of the quantum world at large is the actual physics of how the brain processes information. By contrast with a digital computer, the brain uses both pulse coded action potentials and continuous gradients in an adaptive parallel network. Conscious states tend to be distinguished from subconscious processing by virtue of coherent phase fronts of the brain’s wave excitations. Phase coherence of beats between wave functions [fig 71\(c\)](#), is also the basis of quantum uncertainty.

In addition, the brain uses edge-of-chaos dynamics, involving the butterfly effect – arbitrary sensitivity to small fluctuations in bounding conditions – and the creation of strange attractors to modulate wave processing, so that the dynamics doesn’t become locked into a given ordered state and can thus explore the phase space of possibilities, before making a transition to a more ordered state representing the perceived solution. Self-organised criticality is also a feature, as is neuronal threshold tuning. Feedback between the phase of brain waves on the cortex and the discrete action potentials of individual pyramidal cells, in which the phase is used to determine the timing of action potentials, creates a feedback between the continuous and discrete aspects of neuronal excitation. These processes, in combination, may effectively invoke a state where the brain is operating as an edge-of-chaos quantum computer by

making internal quantum measurements of its own unstable dynamical evolution, as cortical wave excitons, complemented by discrete action potentials at the axonal level.

Chaotic sensitivity, combined with related phenomena such as stochastic resonance (Liljenström et al. 2005), mean that fractal scale-traversing handshaking (Grosu 2023) can occur between critically poised global brain states, neurons at threshold, ion-channels and the quantum scale, in which quantum entanglement of excitons can occur (King 2014). At the same time these processes underpin why there is ample room in physical brain processing for quantum uncertainty to become a significant factor in unstable brain dynamics, fulfilling Eccles (1986) notion that this can explain a role for consciousness, without violating any classically causal processes.

This means that brain function is an edge-of-chaos quantum dynamical system which, unlike a digital computer, is far from being a causally deterministic process which would physically lock out any role for conscious decision-making, but leaves open a wide scope for quantum uncertainty, consistent with a role for consciousness in tipping critical states. The key to the brain is thus it's quantum physics, not just its chemistry and biology. This forms a descriptive overview of possible processes involved rather than an empirical proof, in the face of the failure of promissory materialistic neuroscience (Popper & Eccles 1984) to demonstrate physical causal closure of the universe, so Occam's razor cuts in the direction which avoids conflict with empirical experience of conscious volitional efficacy over the physical universe.

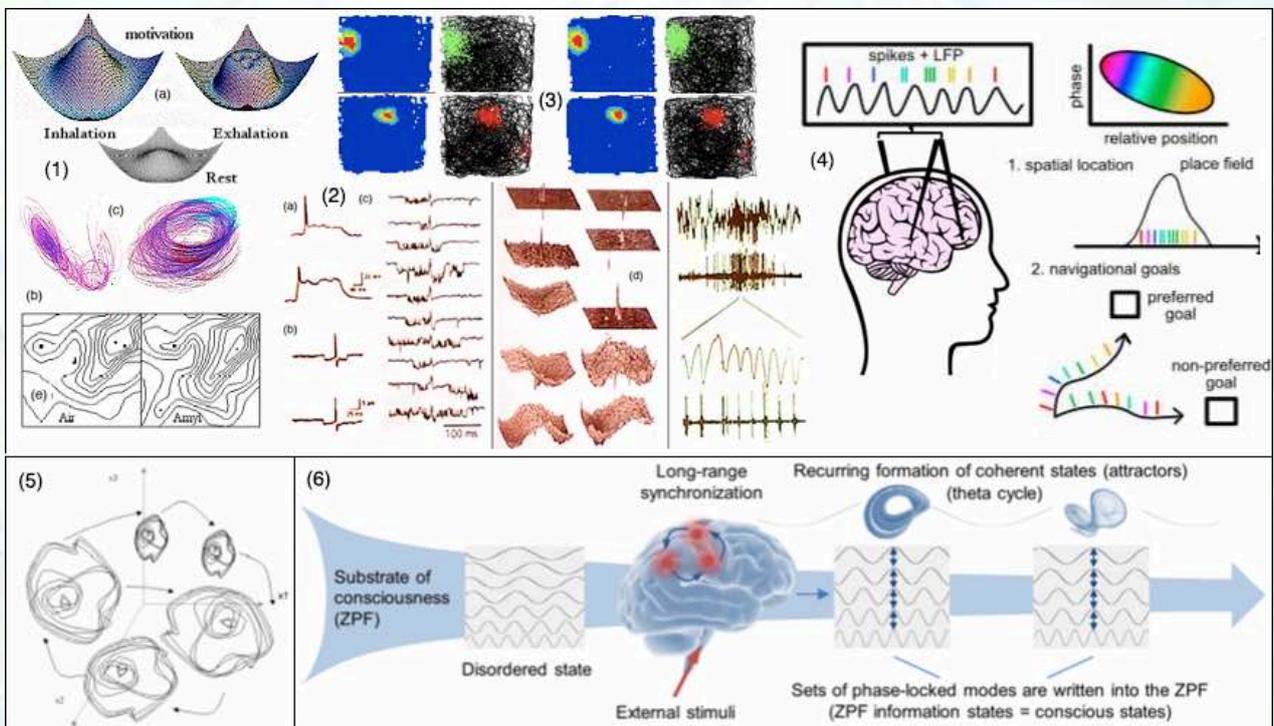

Fig 78: (1) Edge of chaos transitions model of olfaction (Freeman 1991). (2) Stochastic resonance as a hand-shaking process between the ion channel and whole brain states (Liljenström & Svedin 2005). (3) Hippocampal place maps (erdiklab.technion.ac.il). Hippocampal cells have also been shown to activate in response to desired locations in an animals anticipated future they have observed but not visited (Olafsdottir et al. 2015). (4) Illustration of micro-electrode recordings of local wave phase precession (LFP) enabling correct spatial and temporal encoding via discrete action potentials in the hippocampus (Qasim et al. 2021). This shows that the EEG is not just an epiphenomenal artefact of collective action potentials but an active continuous wave to which neurons respond with phase modulation. Delta, theta, alpha beta and gamma bands appear to have distinct functions and dynamics and metastable and spiral waves have been noted as having neurocognitive function (Roberts et al. 2019, Xu et al. 2023,). (5) Living systems are dynamical systems. They show ensembles of eigenbehaviours, which can be seen as unstable dynamical tendencies in the trajectory of the system. Francisco Varela's neurophenomenology (Varela 1996, Rudrauf et al. (2003) is a valid attempt to bridge the hard and easy problems, through a biophysics of being, by developing a complementary subjective account of processes corresponding to objective brain processing. While these efforts help to elucidate the way brain states correspond to subjective experiences, using an understanding of resonant interlocking dynamical systems, they do not of themselves solve the subjective nature of the hard problem. (6) Joachim Keppler's (2018, 2021, James et al. 2022) view of conscious neural processing uses the framework of stochastic electrodynamics (SED), a branch of physics that affords a look behind the uncertainty of quantum field theory (QFT), to derive an explanation of the neural correlates of consciousness, based on the notion that all conceivable shades of phenomenal awareness are woven into the frequency spectrum of a universal background field, called zero-point field (ZPF), implying that the fundamental mechanism underlying conscious systems rests upon the access to information available in the ZPF. This gives an effective interface description of how dynamical brain states correspond to subjective conscious experiences, but like the other dynamical descriptions, does not solve the hard problem itself of why the zero point field becomes subjective.

Diverse Theories of Consciousness

Descriptions of the actively conscious brain revolve around extremely diverse conceptions. The neural network approach conceives of the brain as a network of neurons connected by axonal-dendritic synapses, with action potentials as discrete impulses travelling down the long pyramidal cell axons through which activity is encoded as a firing rate. In this view the notions of “brain waves” as evidenced in the EEG (electroencephalogram) and MEG (magnetoencephalogram) are just the collective averages of these spikes, having no function in themselves, being just an accessory low intensity electromagnetic cloud associated with neuronal activity, which happens to generate a degree of coupled synchronisation through the averaged excitations of the synaptic web. At the opposite extreme are field theories of the conscious brain in which fields have functional importance in themselves and help to explain the “binding” problem of how conscious experiences emerge from global brain dynamics. Into the mix are also abstract theories of consciousness such as Tononi and Koch’s (2015) IIT or integrated information theory and Graziano’s (2016) AST or attention schema theory, which attempt to formulate an abstract basis for consciousness that might arise in biological brains or synthetic neural networks given the right circumstances.

Fig 79: Overview of Theories of Consciousness reviewed, with rough comparable positions.

Field or field-like theories are in

blue/magenta. Explicit AI support **magenta/red**. Horizontal positions guided by specific author statements.

The mushroom experience that triggered Symbiotic Existential Cosmology caused a reversal of world view from my original point of view, King (1996), looking for the neurodynamic and quantum basis of consciousness in the brain, to realising

that no such theory is possible because a pure physicalist theory cannot bridge the hard problem explanatory gap in the quantum universe, due to the inability to demonstrate causal closure.

No matter how fascinating and counter-intuitive the complexities of the quantum, physical and biological universe are, no purely physicalist description of the neurodynamics of consciousness can possibly succeed, because it is scientifically impossible to establish a theoretical proof, or empirical demonstration, of the causal closure of the physical universe in the context of neurodynamics. The bald facts are that, no matter to what degree we use techniques, from optogenetics, through EcoG, to direct cell recording, there is no hope within the indeterminacies of the quantum universe of making an experimental verification of classical causal closure. Causal closure of the physical universe thus amounts to a formally undecidable cosmological proposition from the physical point of view, which is heralded as a presumptive 'religious' affirmative belief without scientific evidence, particularly in neuroscience. The hard problem of consciousness is thus cosmological, not biological, or neurodynamic alone. Symbiotic Existential Cosmology corrects this by a minimal extension of quantum cosmology by adding the axiom of primal subjectivity, as we shall see below.

In stark contrast, the subjective experiential viewpoint perceives conscious volition over the physical universe as an existential certainty that is necessary for survival. When any two live human agents engage in a frank exchange of experiences and communications, such as my reply to you all now, which evidences my drafting of a consciously considered opinion and intentionally sending it to you in physical form, this can be established beyond reasonable doubt by mutual affirmation of our capacity to consciously and intentionally respond with a physical communication. This is the way living conscious human beings have always viewed the universe throughout history and it is a correct veridical empirical experience and observation of existential reality, consistent with personal responsibility, criminal and civil law on intent, all long-standing cultural traditions and the fact that 100% of our knowledge of the physical world comes through our conscious experience of it. Neuroscientists thus contradict this direct empirical evidence at their peril.

However there is still a practical prospect of refining our empirical understanding of the part played by neurodynamics in generating subjective conscious experience and volition over the physical universe through current and upcoming techniques in neuroscience. What these can do is demonstrate experimentally the nature of the neurodynamics occurring, when conscious experiences are evoked, the so-called "neural correlate of consciousness", forming an interface with conscious experience our and ensuing decision-making actions.

To succeed at this scientific quest, we need to understand how quantum cosmology enters into the formation of biological tissues. The standard model of physics is symmetry broken, between the colour, weak, and EM forces and gravity, which ensures that there are a hundred positively charged atomic nuclei, with orbital electrons having both periodic quantum properties of the *s*, *p*, *d*, & *f*, orbitals and non-linear EM charge interactions, centred on first row covalent H-CNO modified by P & S and light ionic and transition elements, as shown in fig 51, to form a fractal cooperative bonding cascade from organic molecules like the amino acids and nucleotides, through globular proteins and nucleic acids, to complexes like the ribosome, and membrane, to cell organelles, cells and tissues. These constitute an interactive quantum form of matter – the most exotic form of matter in existence, whose negentropic thermodynamics in living systems is vastly more challenging than the quantum properties of solid state physics and its various excitons and quasi-particles. Although these are now genetically and enzymatically encoded, the underlying fractal dynamics is a fundamental property of cosmological symmetry-breaking and abiogenesis. It introduces a cascade of quantum effects, in protein folding, allosteric active sites with tunnelling, membrane ionic and electron transport and ultimately neurodynamics. Furthermore biological processes are non IID, not constituting identical independently distributed quantum measurements, so do not converge to the classical description and remain collectively quantum in nature throughout, spanning all or most aspects of neuronal excitability and metabolism.

This means that current theories of the interface between CNS neurodynamics and subjective conscious volition are all manifestly incomplete and qualitatively and quantitatively inadequate to model or explain the brain-experience interface. Symbiotic Existential Cosmology has thus made a comprehensive review of these, including GNW (Dehane et al.), ART (Grossberg), DQF (Freeman & Vitiello), ZPF (Keppler), AST (Graziano), CEMI (McFadden), FEM (Solms & Friston), IIT (Tononi & Koch), PEM (Poznanski et al.), as well as outliers like ORCH (Hameroff & Penrose). The situation facing TOEs of consciousness are, despite experimental progress, in a more parlous state than physical TOEs, from supersymmetric, superstring, and membrane theories to quantum loop gravity, that as yet show no signs of unification over multiple decades. In both fields, this requires a foundation rethink and a paradigm shift. Symbiotic Existential Cosmology provides this to both fields simultaneously.

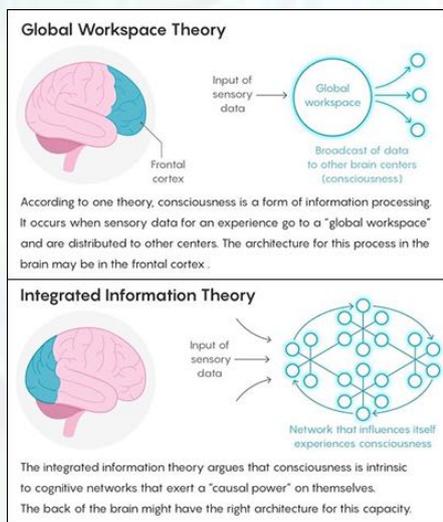

To understand this biologically, we need to understand that the nature of consciousness as we know it and all its key physical and biological features, arose in a single topological transition in the eucaryote endosymbiosis, when the cell membrane became freed for edge-of-chaos excitation and receptor-based social signalling, through the same processes that are key to human neurodynamics today, when respiration became sequestered in the mitochondria. This in turn led to the action potential via the flagellar escape reaction, and to the graded membrane potentials and neurotransmitter receptor-based synaptic neural networks we see in neuronal excitation. It took a billion years later before these purposive processes enabling sentience at the cellular level, in the quantum processes we now witness in vision, audition, olfaction and feeling sensation became linked in the colonial neural networks illustrated by hydra and later the more organised brains of arthropods, vertebrates and cephalopods. This means that a purely neural network view of cognition and consciousness is physically inadequate at the foundation. Moreover the brain derives its complexity not just from our genome which is vastly too small to generate the brain's complexity, but interactive processes of cell migration in the developing brain that form a self organising system through mutual neuronal recognition by neurotransmitter type and mutual excitation/inhibition.

Of these theories, GNW is the closest to a broad brush strokes, empirically researched account. Neural network theories like Grossman's ART generate crude necessary but insufficient conditions for consciousness because they lack almost all the biological principle involved. Pure abstract theories like IIT do likewise. Specialised quantum theories like Hameroff & Penrose are untenable both in current biology and fundamentally in evolutionary terms because they have been contrived as quantum back-pack of oddball quantum processes such as quantum microtubular CAs, not confluent with evolutionary processes, using increasingly contrived speculation to make up for inadequacies e.g. in linking cellular processes through condensates. ORCH is also objective reduction, so it cannot address conscious volition.

There is good empirical support for two processes in brain dynamics. (1) Edge-of-chaos transitions from a higher energy more disordered dynamic to a less disordered attractor dynamic, which is also the basis of annealing in neural

network models of a potential energy landscape. (2) Phase tuning between action potential timing in individual neurons and continuous local potential gradients, forming an analogue with quantum uncertainty based measurement of wave beats.

These mean that field and field like-theories such as ZPF, DQF and PEM all have a degree of plausibility complementing bare neural network descriptions. However all these theories run into the problem of citing preferred physical mechanisms over the complex quantum system picture manifest in tissue dynamics. ZPF cites the zero-point field, effectively conflating a statistical semi-classical of QED with subjective consciousness as the quantum vacuum. It cites neurotransmitter molecular resonances at the synapse and periodic resonances in the brain as providing the link. DQF is well grounded in Freeman dynamics, but cites water molecule structures, which are plausible but accessory and not easy to test. PEM cites quasi-polaritonic waves involving interaction between charges and dipoles, with an emphasis on delocalised orbitals, which are just one of many quantum level processes prominently involved in respiration and photosynthesis and makes a claim to "microfeels" as the foundation of a definition of precognitive information below the level of consciousness. It also restricts itself to multiscale thermodynamic holonomic processes, eliminating the quantum level, self organised criticality and fractality.

Philosopher wins 25 year long bet with Neuroscientist (Lenharo 2023): In 1998, neuroscientist Christof Koch bet philosopher David Chalmers that the mechanism by which the brain's neurons produce consciousness would be discovered by 2023. Both scientists agreed publicly on 23 June, at the annual meeting of the Association for the Scientific Study of Consciousness that it is an ongoing quest — and declared Chalmers the winner.

What ultimately helped to settle the bet was a study testing two leading hypotheses about the neural basis of consciousness – IIT and GNW (Cogitate Consortium et al. 2023). Consciousness is everything that a person experiences — what they taste, hear, feel and more. It is what gives meaning and value to our lives, Chalmers says. However, despite a vast effort, researchers still don't understand how our brains produce it. "It started off as a very big philosophical mystery," Chalmers adds. "But over the years, it's gradually been transmuting into, if not a 'scientific' mystery, at least one that we can get a partial grip on scientifically." It tested two of

the leading hypotheses: integrated information theory (IIT) and global network workspace theory (GNWT). IIT proposes that consciousness is a 'structure' in the brain formed by a specific type of neuronal connectivity that is active for as long as a certain experience, such as looking at an image, is occurring. This structure is thought to be found in the posterior cortex, at the back of the brain. GNWT, by contrast, suggests that consciousness arises when information is broadcast to areas of the brain through an interconnected network. The transmission, according to the theory, happens at the beginning and end of an experience and involves the prefrontal cortex, at the front of the brain. The results didn't perfectly match either of the theories. This has since resulted in an open letter treating IIT, in particular as pseudoscience (Fleming et al. 2023 Lenharo 2023b, 2024).

The position of Symbiotic Existential Cosmology is that none of these theories, and particularly those that depend on pure physical materialism, have any prospect of solving the hard problem and particularly the hard problem extended to volition. Symbiotic Existential Cosmology therefore adopts a counter strategy to add an additional axiom to quantum cosmology that associates primal subjectivity and free will with an interface in each quantum, where "consciousness" is manifested in the special relativistic space-time extended wave function and "free will" is manifested in the intrinsic uncertainty of quantum collapse to the particle state. This primal subjectivity exists in germinal forms in unstable quantum-sensitive systems such as butterfly effect systems and becomes intentional consciousness as we know it in the eucaryote transition.

This transforms the description of conscious dynamics into one in which subjectivity is compliant with determined perceived and cognitive factors but utilises the brain state as a contextual environmental filter to deal with states of existential uncertainty threatening the survival of the organism. This is similar to AST, but without the utopian artificial intelligence emphasis it shares with others such as ART, IIT, and PEM. Key environmental survival questions are both computationally intractable and formally uncomputable, because the tiger that may pounce is also a conscious agent who can adapt their volitional strategy to unravel any computational "solution". This provides a clean physical cut, in

which subjective consciousness remains compliant with the determined boundary conditions realised by the cognitive brain, but has decision-making ability in situations when cellular or brain dynamics becomes unstable and quantum sensitive. No causal conflict thus arises between conscious intent restricted to uncertainty and physical causes related to the environmental constraints. It invokes a model of quantum reality where uncertainty is not merely random, but is a function of unfolding environmental uncertainty as a whole. This is the survival advantage cellular consciousness fixed in evolution through anticipating existential crises and has conserved ever since, complementing cerebral cognition in decision-making. This is reflected experientially in how we make intuitive "hunch" overall decisions and physically in certain super-causal forms of the transactional QM interpretation and super-determinism, both of which can have non-random quasi-ergodic hidden variable interpretations and are compatible with free will.

The final and key point is that Symbiotic Existential Cosmology is biospherically symbiotic. Through this, the entire cosmology sees life and consciousness as the ultimate interactive climactic crisis of living complexity interactively consummating the universe, inherited from cosmological symmetry-breaking, in what I describe as conscious paradise on the cosmic equator in space-time. Without the symbiosis factor, humanity as we stand, will not survive a self-induced Fermi extinction, caused by a mass extinction of biodiversity, so the cosmology is both definitively and informatively accurate and redemptive, in long-term survival of the generations of life over evolutionary time scales.

Susan Pockett (2013) explains the history of the diverging synaptic neural network and field theoretic views:

Köhler (1940) did put forward something he called "field theory". Köhler only ever referred to electric fields as cortical correlates of percepts. His field theory was a theory of brain function. Lashley's test was to lay several gold strips across the entire surface of one monkey's brain, and insert about a dozen gold pins into a rather small area of each hemispheric visual cortex of another monkey. The idea was that these strips or pins should short-circuit the hypothesized figure currents, and thereby (if Köhler's field theory was correct) disrupt the monkeys' visual perception. The monkeys performed about as well on this task after insertion of the pins or strips as they had before (although the one with the inserted pins did "occasionally fail to see a small bit of food in the cup") and Lashley felt justified in concluding from this that "the action of electric currents, as postulated by field theory, is not an important factor in cerebral integration." Later Roger Sperry did experiments similar to Lashley's, reporting similarly negative results.

Intriguingly, she notes that Libet, whom we shall meet later despite declaring the readiness potential preceded consciousness, also proposed a near-supernatural field theory:

Libet proposed in 1994 that consciousness is a field which is "not ... in any category of known physical fields, such as electromagnetic, gravitational etc" (Libet 1994). In Libet's words, his proposed Conscious Mental Field "may be viewed as somewhat analogous to known physical fields ... however ... the CMF cannot be observed directly by known physical means."

Pockett (2014) describes what she calls "process theories":

The oldest classification system has two major categories, dualist and monist. Dualist theories equate consciousness with abstracta. Monist (aka physicalist) theories equate it with concreta. A more recent classification (Atkinson et al., 2000) divides theories of consciousness into process theories and vehicle theories: it says "Process theories assume that consciousness depends on certain functional or relational properties of representational vehicles, namely, the computations in which those vehicles engage. The relative number of words devoted to process and vehicle theories in this description hints that at present, process theories massively dominate the theoretical landscape. But how sensible are they really?"

She then discusses both Tononi & Koch's (2015) IIT integrated information theory and Chalmers' (1996) multi-state "information spaces". And lists the following objections:

First, since information is explicitly defined by everyone except process theorists as an objective entity, it is not clear how process theorists can reasonably claim either that information in general, or that any subset or variety of information in particular, is subjective. No entity can logically be both mind-independent and the very essence of mind. Therefore, when process theorists use the word "information" they must be talking about something quite different from what everyone else means by that word. Exactly what they are talking about needs clarification. **Second**, since information is specifically defined by everybody (including Chalmers) as an abstract entity, any particular physical realization of information does not count as information at all. **Third**, it is a problem at least for scientists that process theories are untestable. The hypothesis that a particular brain process **correlates with** consciousness can certainly be tested empirically. But the only potentially testable prediction of theories that claim identity between consciousness and a particular kind of information or information processing is that this kind of information or information processing will be conscious no matter how it is physically instantiated.

These critiques will apply to a very broad range of theories of consciousness we shall explore, including many in fig 79 that do not limit themselves to the neural correlate of consciousness.

Theories of consciousness have, in the light of our understanding of brain processes gained from neuroscience, become heavily entwined with the objective physics and biology of brain function. Michel & Doerig (2021), in reviewing local and global theories of consciousness summarise current thinking, illustrating this dependence on neuroscience for understanding the enigmatic nature of consciousness.

Localists hold that, given some background conditions, neural activity within sensory modules can give rise to conscious experiences. For instance, according to the local recurrence theory, reentrant activity within the visual system is necessary and sufficient for conscious visual experiences. **Globalists** defend that consciousness involves the large-scale coordination of a variety of neuro-cognitive modules, or a set of high-level cognitive functions such as the capacity to form higher-order thoughts about one's perceptual states. Localists tend to believe that consciousness is rich, that it does not require attention, and that phenomenal consciousness overflows cognitive access. Globalists typically hold that consciousness is sparse, requires attention, and is co-extensive with cognitive access.

According to local views, a perceptual feature is consciously experienced when it is appropriately represented in sensory systems, given some background conditions. As localism is a broad family of theories, what "appropriately" means depends on the local theory under consideration. Here, we consider only two of the most popular local theories: the micro-consciousness theory, and the local recurrence theory, focusing on the latter. According to the micro-consciousness theory "processing sites are also perceptual sites". This theory is extremely local. The simple fact of representing a perceptual feature is sufficient for being conscious of that feature, given some background conditions. One becomes conscious of individual visual features before integrating them into a coherent whole. According to the local recurrence theory, consciousness depends on "recurrent" activity between low- and higher-level sensory areas. Representing a visual feature is necessary, but not sufficient for being conscious of it. The neural vehicle carrying that representation must also be subject to the right kind of recurrent dynamics. For instance, consciously perceiving a face consists in the feedforward activation of face selective neurons, quickly followed by a feedback signal to lower-level neurons encoding shape, color, and other visual features of the face, which in turn modulate their activity as a result.

The authors also stress post-dictive effects as a necessary non-local condition for consciousness, which may last a third of a second after an event:

In postdictive effects, conscious perception of a feature depends on features presented at a later time. For instance, in feature fusion two rapidly successive stimuli are perceived as a single entity. When a red disk is followed by a green disk after 20ms, participants report perceiving a single yellow disk, and no red or green disk at all. This is a postdictive effect. Both the red and green disks are required to form the yellow percept. The visual system must store the representation of the first disk until the second disk appears to integrate both representations into the percept that subjects report having. Many other postdictive effects in the range of 10-150ms have been known for decades and are well documented. Postdictive effects are a challenge for local theories of consciousness. Features are locally represented in the brain but the participants report that they do not see those features.

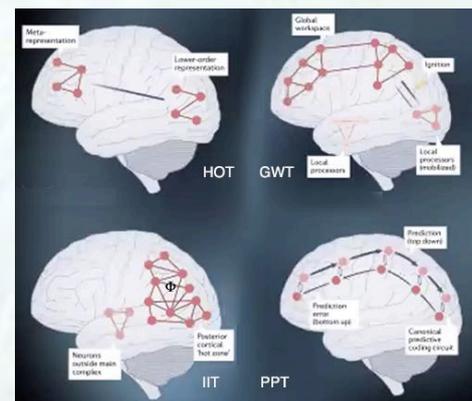

This can have the implication that unconscious brain processes always precede conscious awareness, leading to the conclusion that our conscious awareness is just a post-constructed account of unconscious processes generated by the brain and that subjective consciousness, along the experience of volition have no real basis, leading to a purely physically materialist account of subjective consciousness as just an internal model of reality constructed by the brain.

Pockett (2014) in supporting her own field theory of consciousness, notes structural features that may exclude certain brain regions from being conscious in their own right:

It is now well accepted that sensory consciousness is not generated during the first, feed-forward pass of neural activity from the thalamus through the primary sensory cortex. Recurrent activity from other cortical areas back to the primary or secondary sensory cortex is necessary. Because the feedforward activity goes through architectonic Lamina 4 of the primary sensory cortex (which is composed largely of stellate cells and thus does not generate synaptic dipoles) while recurrent activity operates through synapses on pyramidal cells (which do generate dipoles), the conscious em patterns resulting from recurrent activity in the 'early' sensory cortex have a neutral area in the middle of their radial pattern. The common feature of brain areas that can not generate conscious experience – which are now seen to include motor cortex as well as hippocampus, cerebellum and any sub-cortical area – is that they all lack an architectonic Lamina 4 [layer 4 of the cortex].

Seth & Bayne (2022) provide a detailed review of theories of consciousness from the perspective of neuroscience. They investigate four key types of TOC as listed below and also provide table 1 below listing a diverse range of TOCs.

(1) **Higher-order theories HOT** The claim uniting all these is that a mental state is conscious in virtue of being the target of a certain kind of meta-representational state. These are not representations that occur higher or deeper in a processing hierarchy but are those that have as their targets

other (implicitly subjective) representations.

- (2) **Global workspace theories GWT** originate from architectures, in which a “blackboard” is a centralised resource through which specialised processors share and receive information. The **first** was framed at a cognitive level and proposed that conscious mental states are those that are ‘globally available’ to a wide range of cognitive processes – attention, evaluation, memory and verbal. They claim that it is wide accessibility of information to such systems that constitutes conscious experience. This has been developed into **GNW** ‘global neuronal work space theory’.
- (3) **Integrated information theory IIT** advances a mathematical approach to characterising phenomenology. It starts by proposing axioms about the phenomenological character of conscious experiences (that is, properties that are taken to be self-evidently true and general to consciousness), and from these, it derives claims about the properties that any physical substrate of consciousness must satisfy, proposing that physical systems that instantiate these properties necessarily also instantiate consciousness.
- (4) **Re-entry and predictive processing theories PPT** The first associate conscious perception with topdown (recurrent, reentrant) signalling. The second group are not primarily ToCs but more general accounts of brain (and body) function that can be used to formulate explanations and predictions regarding properties of consciousness.

| | |
|--|--|
| Higher-order theory (HOT) | Consciousness depends on meta-representations of lower-order mental states |
| Self-organizing meta-representational theory | Consciousness is the brain’s (meta-representational) theory about itself |
| Attended intermediate representation theory | Consciousness depends on the attentional amplification of intermediate-level representations |
| Global workspace theories (GWTs) | Consciousness depends on ignition and broadcast within a neuronal global workspace where fronto-parietal cortical regions play a central, hub-like role |
| Integrated information theory (IIT) | Consciousness is identical to the cause–effect structure of a physical substrate that specifies a maximum of irreducible integrated information |
| Information closure theory | Consciousness depends on non-trivial information closure with respect to an environment at particular coarse-grained scales |
| Dynamic core theory | Consciousness depends on a functional cluster of neural activity combining high levels of dynamical integration and differentiation |
| Neural Darwinism | Consciousness depends on re-entrant interactions reflecting a history of value-dependent learning events shaped by selectionist principles |
| Local recurrency | Consciousness depends on local recurrent or re-entrant cortical processing and promotes learning |
| Predictive processing | Perception depends on predictive inference of the causes of sensory signals; provides a framework for systematically mapping neural mechanisms to aspects of consciousness |
| Neuro-representationalism | Consciousness depends on multilevel neurally encoded predictive representations |
| Active inference | Although views vary, in one version consciousness depends on temporally and counterfactually deep inference about self-generated actions |
| Beast machine theory | Consciousness is grounded in allostatic control-oriented predictive inference |
| Neural subjective frame | Consciousness depends on neural maps of the bodily state providing a first-person perspective |
| Self comes to mind theory | Consciousness depends on interactions between homeostatic routines and multilevel interoceptive maps, with affect and feeling at the core |
| Attention schema theory | Consciousness depends on a neurally encoded model of the control of attention |
| Multiple drafts model | Consciousness depends on multiple (potentially inconsistent) representations rather than a single, unified representation that is available to a central system |
| Sensorimotor theory | Consciousness depends on mastery of the laws governing sensorimotor contingencies |
| Unlimited associative learning | Consciousness depends on a form of learning which enables an organism to link motivational value with stimuli or actions that are novel, compound and non-reflex inducing |
| Dendritic integration theory | Consciousness depends on integration of top-down and bottom-up signalling at a cellular level |
| Electromagnetic field theory | Consciousness is identical to physically integrated, and causally active, information encoded in the brain’s global electromagnetic field |
| Orchestrated objective reduction | Consciousness depends on quantum computations within microtubules inside neurons |

Table 1: The full spread of TOCs, as listed in Seth & Bayne (2022).

They note a version of the measurement problem, that to test a theory of consciousness (ToC), we need to be able to reliably detect both consciousness and its absence. At present, experimenters tend to rely on a subject's introspective capacities to identify their states of consciousness. However, they claim this approach is problematic. Firstly they claim reliability of introspection is questionable. This is a debatable claim, which tends to lead to devaluing subjective reports, possibly unfairly, in an emphasis on "objective observations", which render subjective consciousness as having an orphan status, defeating the very purpose of TOCs in relation to the hard problem. They also note infants, individuals with brain damage and non-human animals, who might be conscious, but are unable to produce introspective reports, claiming there is a pressing need to identify non-introspective 'markers' or 'signatures' of consciousness — such as the perturbational complexity index (PCI) and the optokinetic nystagmus response, or distinctive bifurcations in neural dynamics, as markers of either general, or specific kinds of conscious contents. These however are purely functional measures of what consciousness actually is, as experienced phenomena.

In addressing the 'hard problem' they distinguish the easy problems concerned with the functions and behaviours associated with consciousness, from the hard problem, which concerns the experiential dimensions of consciousness, noting that what makes the hard problem hard is the 'explanatory gap' — the intuition that there seems to be no prospect of a fully reductive explanation of experience in physical or functional terms. Integrated information theory and certain versions of higher-order theory address the hard problem directly, while other theories such as global workspace theories focus on the functional and behavioural properties normally associated with consciousness, rather than the hard problem, noting that some predictive processing theorists aim to provide a framework in which various questions about the phenomenal properties of consciousness can be addressed, without attempting to account for the existence of phenomenology — an approach called the 'real problem'.

They posit that a critical question is whether the hard problem is indeed a genuine challenge that ought to be addressed by a science of consciousness, or whether it ought to be dissolved rather than solved as the solving easy problems first strategy invokes. The 'dissolvers' argue that the appearance of a distinctively hard problem derives from the peculiar features of the 'phenomenal concepts' that we employ in representing our own conscious states, citing illusionism, in which we do not have phenomenal states but merely represent ourselves as having such states, speculating that the grip of the hard problem may loosen as our capacity to explain, predict and control both phenomenological and functional properties of consciousness expands, thus effectively siding with the dissolvers.

In conclusion, they note that present, ToCs are generally used as 'narrative structures' within the science of consciousness. Although they inform the interpretation of neural and behavioural data, they demure that it is still rare for a study to be designed with questions of theory validation in mind. Although there is nothing wrong with employing theories in this manner, claiming future progress will depend on experiments that enable ToCs to be tested and disambiguated. This is the kind of ideal that we will expect physicalist neuroscientists to veer into, but it runs the risk of 'sanitising' consciousness, just as behaviourism has done in psychology to its nemesis.

Pivotal are two questions, one is the physicalist quest to use the easy functionalist notions of consciousness to explain away the hard problem of consciousness, which typifies Levine's explanatory gap, Nagel's what it is "to be like" something something conscious and Chalmers' notion "how we have phenomenal first-person subjective experiences". This is really not about the general questions of consciousness, such as "consciousness of" something, which can be viewed as a form of global attention that can be described functionally, and more specific notions like self-consciousness i.e. awareness of a form of functional agency, both of which could apply equally to artificial intelligence. This becomes clear when we examine the authors' choice of key theories of consciousness, several of which are not targeted at the hard problem at all, as they point out, knowing that Seth for example favours an ultimate functional explanation which will "dissolve" the hard problem, even if it is a form of identity theory, or dual aspect monism. Really we need to distinguish consciousness from subjective consciousness — the ability to have subjective experiences and thus subjectivity itself and its cosmological status, rather than the mere functionality of consciousness as a global attentive process. This is why Symbiotic Existential Cosmology deals directly with primal subjectivity as a cosmological complement to the physical universe to capture the notion of subjectivity squarely and independently of consciousness. This leaves full consciousness an emergent property of the eucaryote endo-symbiosis that results in the cellular mechanisms of edge-of-chaos excitable membrane and informational membrane signalling using

neurotransmitters, both of which are functionally emergent properties but with non-classical implications in the quantum universe.

We can immediately see this is a critically important step, when we see the above research being cited as a basis to determine whether future AI developments would be considered “conscious”, as Butlin et al. (2023) cite precisely the functional expressions of the same theories of consciousness as above, to provide criteria where a purely objective physical process could become “conscious”, in view of its functional properties in recurrent processing, global workspace, higher-order processes, attention schemas predictive processing and functional agency, none of which address the hard problem, let alone the extended hard problem of subjective volition over the physical universe.

| |
|---|
| Recurrent processing theory |
| RPT-1: Input modules using algorithmic recurrence |
| RPT-2: Input modules generating organised, integrated perceptual representations |
| Global workspace theory |
| GWT-1: Multiple specialised systems capable of operating in parallel (modules) |
| GWT-2: Limited capacity workspace, entailing a bottleneck in information flow and a selective attention mechanism |
| GWT-3: Global broadcast: availability of information in the workspace to all modules |
| GWT-4: State-dependent attention, giving rise to the capacity to use the workspace to query modules in succession to perform complex tasks |
| Computational higher-order theories |
| HOT-1: Generative, top-down or noisy perception modules |
| HOT-2: Metacognitive monitoring distinguishing reliable perceptual representations from noise |
| HOT-3: Agency guided by a general belief-formation and action selection system, and a strong disposition to update beliefs in accordance with the outputs of metacognitive monitoring |
| HOT-4: Sparse and smooth coding generating a “quality space” |
| Attention schema theory |
| AST-1: A predictive model representing and enabling control over the current state of attention |
| Predictive processing |
| PP-1: Input modules using predictive coding |
| Agency and embodiment |
| AE-1: Agency: Learning from feedback and selecting outputs so as to pursue goals, especially where this involves flexible responsiveness to competing goals |
| AE-2: Embodiment: Modeling output-input contingencies, including some systematic effects, and using this model in perception or control |

Table 2: Indicator Properties (Butlin et al. 2023).

Butlin et al. note: *This report argues for, and exemplifies, a rigorous and empirically grounded approach to AI consciousness: assessing existing AI systems in detail, in light of our best-supported neuroscientific theories of consciousness. We survey several prominent scientific theories of consciousness. From these theories we derive “indicator properties” of consciousness, elucidated in computational terms that allow us to assess AI systems for these properties. We use these indicator properties to assess several recent AI systems, and we discuss how future systems might implement them. Our analysis suggests that no current AI systems are conscious, but also suggests that there are no obvious technical barriers to building AI systems which satisfy these indicators.*

Polák & Marvan (2019), in a different kind of “dissolving” approach to the hard problem, attempt to assert dual theories, in which scientists study pairs of phenomenal mental states of which one is and the other is not conscious, the presence/absence of consciousness being their sole distinguishing feature, claiming this facilitates unpacking the unitary nature of the hard problem, thus partly decomposing it.

They note that Chalmers (2018 30) contains the acceptance of unconscious sensory qualities, saying such a move is: *perhaps most promising for deflating the explanatory gap tied to qualities such as redness: if these qualities [...] can occur unconsciously, they pose less of a gap. As before, however, the core of the hard problem is posed not by the qualities themselves but by our experience of these qualities: roughly, the distinctive phenomenal way in which we represent the qualities or are conscious of them.*

They cite two examples of separation of brain processes forming a neural correlate conscious experiences. The first is hemispheric visual neglect caused by localised brain damage such as a stroke, where information in the neglected hemisphere appears to unconsciously influence a person's choices:

Unilateral visual neglect, the inability to see objects in one half of the visual field, might serve as an illustration. In the most famous neglect example (Marshall and Halligan, 1988), a person cannot consciously discriminate between two depicted houses. The houses are identical except that one of them is on fire in that half of the visual field the person, due to neglect, cannot see. Although the person was constantly claiming that both houses look the same to her, she repeatedly said she would prefer to live in the house not consumed by the flames.

A second example cites Lamme's (2006, 2015) theory of brain processes which may constitute separate phases in the generation of a conscious experience, which permit clean separation of the brain mechanisms for the creation of phenomenal content from the mechanism that "pushes this content into consciousness":

The theory revolves around the notion of local recurrent neural activity within the cortex and decomposes the formation of conscious visual content into two phases. The first one is called fast feedforward sweep. It is a gradual activation of different parts of the visual system in the brain. The dual view interprets this process as the formation of the unconscious but phenomenal mental state. A later process, that may or may not occur, is called recurrent activity. It is a neural feedback processing during which higher visual centers send the neural signal back to the lower ones. The time delay between the initiation of the first and the second process might be seen as corresponding to the difference between processing of the phenomenal character (feedforward sweep) and making and maintaining this phenomenal character conscious (recurrent processing).

They note that in several other theories already listed, including Global Neural Workspace theory, thalamo-cortical circuits, and apical amplification within the cortical pyramidal neurons, the phase of phenomenal content creation and the phase of this content becoming conscious are distinguishable. But all these theories are describing purely physical brain processes, being imbued with subjective aspects only by inference. So we need to look carefully at how the authors treat subjectivity itself. Essentially they are making a direct attack on the unitary nature of subjective conscious experience by attempting to separate consciousness from phenomenal experience so subjectivity is being held hostage in the division:

What constantly fuels this worry, we believe, is taking the conscious subjective phenomenal experience to be something monolithic. The peculiar nature of subjective qualities and their being conscious comes as a package and it is difficult to conceive how science might begin explaining it. ... The conscious subjective experience is being felt as something unitary, we grant that. But that does not mean that if we look behind the subjective level and try to explain how such unitary experience arises, the explanation itself has to have unitary form. ... Awareness in this sense is simply the process, describable in neuroscientific terms, of making the sensory qualities conscious for the subject. We could then keep using the term "consciousness" for the subjectively felt unitary experience, while holding that in reality this seemingly unitary thing is the result of an interaction between the neural processes constituting the phenomenal contents and the neural processes constituting awareness.

This effectively a form of physicalist illusionism (Frankish 2017), because, the claim made is that subjective experience is falsely represented as integrated when the underlying physical reality is subdivided by the dual interpretation. It is an illustration of how functionalist theories of consciousness can be misused in an attempt to form a bridgehead decomposing the unitarity of subjective consciousness into interacting divisible physical systems, simply because multiple physical processes are held to be functional, or temporally sequential components, of the associated integrated brain processing state. The trouble with this is that these functional processes can invoke an integrated conscious experience only when they are functionally confluent, so we can't actually separate "the fast feedforward sweep" from the "recurrent activity" in generating a real conscious experience and in pathological cases like hemispherical visual neglect this provides no evidence that healthy integrated conscious brain processes can be so decomposed into dual states.

By contrast with theories of consciousness based on the physical brain alone, in Symbiotic Existential Cosmology, subjectivity is itself a primal cosmological complement to the physical universe. It thus explains subjective conscious experience as a cosmological, rather than just a purely biological or neuroscience phenomenon, thus giving validation and real meaning to our experience of subjective conscious volition over the physical universe, expressed in all our behavioural activities and our sense of personal responsibility for our actions and leads towards a state of biospheric symbiosis as climax living diversity across the generations of life as a whole, ensuring our continued survival.

Psychotic Fallacies of the Origin of Consciousness

Theories of consciousness that are poles apart from any notion of the subjectivity of conscious experience, or the hard problem of consciousness and the explanatory gap of the physical description, arise from treating consciousness merely as purely a type of culturally derived cognitive process. Such theories fall into the philosophers trap of confining the nature of the discourse to rational processes and arguments, which fail to capture the raw depths of subjective experience, characteristic of mystical, shamanic and animistic cultures.

In "The Origin of Consciousness in the Bicameral Mind", Julian Jaynes (1976, 1986) claimed human "ancestors", as late as the Ancient Greeks did not consider emotions and desires as stemming from their own minds but as the consequences of actions of gods external to themselves. The theory posits that the human mind once operated in a bicameral state in which cognitive functions were divided between one part of the brain which appears to be "speaking", and a second part which listens and obeys and that the breakdown of this division gave rise to "consciousness" in humans. He used the term "bicameral" metaphorically to describe a mental state in which the right hemisphere's experiences were transmitted to the left hemisphere through auditory hallucinations. In the assumed bicameral phase, individuals lacked self-awareness and introspection. Instead of conscious thought, they heard external voices or "gods" guiding their actions and decisions. Jaynes claimed this form of consciousness, devoid of meta-consciousness and autobiographical memory, persisted until about 3,000 years ago, when societal changes led to the emergence of our current conscious mode of thought. Auditory hallucinations experienced by those with schizophrenia, including command hallucinations, paralleled the external guidance experienced by bicameral individuals implying mental illness was a bicameral remnant.

To justify his claim, he highlighted instances in ancient texts like the Iliad and the Old Testament where he claimed there was no evidence of introspection or self-awareness and noted that gods in ancient societies were numerous and anthropomorphic, reflecting the personal nature of the external voices guiding individuals. However in the Epic of Gilgamesh, copies of which are many centuries older than even the oldest passages of the Old Testament, describes introspection and other mental processes.

According to Jaynes, language is a necessary but not sufficient condition for consciousness: language existed thousands of years earlier, but consciousness could not have emerged without language. Williams (2010) defends the notion of consciousness as a social-linguistic construct learned in childhood, structured in terms of lexical metaphors and narrative practice. Ned Block's (1981) review criticism is direct – that it is "ridiculous" to suppose that consciousness is a cultural construction.

Jaynes argued that the breakdown of the bicameral mind was marked by societal collapses and environmental challenges. As people lost contact with external voices, practices like divination and oracles emerged as attempts to reconnect with the guidance they once received. However this shows an ethnocentric rationalist lack of awareness and understanding of how earlier animistic cultures perceived the natural world, in which both humans and natural processes like storms, rivers and trees were imbued with spirits that were interacted with, but by no means were regarded as voices which humans had to blindly obey, but ones in which they were in dynamic interaction as sentient beings. There are diverse existing cultures, from the founding San to the highly evolved Maori, who practice animistic beliefs, actually and metaphorically who were not influenced by political upheavals at the periphery of founding urban cultures and can appreciate their world views in both rational and spiritual terms, while at all times being as fully integrated in their conscious experiences as modern dominant cultures. We know that doctrinal religions have evolved from mystical and animistic roots as means to hold together larger urban societies, but these are no more rational beliefs. Neither are polytheists more bicameral in their thinking than monotheists are, but less starkly absolute. Neither is it true that intelligent primates display evidence of a bicameral mind, but rather a fully adapted social intelligence, attuned by social evolution to facilitate their strategic survival as consciously aware intentional agents.

McGilchrist (2009) reviews scientific research into the complementary role of the brain's hemispheres, and cultural evidence, in his book "The Master and His Emissary", proposing that, since the time of Plato, the left hemisphere of the brain (the "emissary" in the title) has increasingly taken over from the right hemisphere (the "master"), to our detriment. McGilchrist felt that Jaynes's hypothesis was "the precise inverse of what happened" and that rather than a shift from bicameral mentality there evolved a separation of the hemispheres into bicameral mentality. This has far more reality value in the fact that the dominance of rational discourse over subjective conscious experience has risen to the degree that many people cannot rationally distinguish themselves from computational machines.

Field and Wave Theories of Consciousness v Connectome Networks and Action Potentials

Brain dynamics are a function of a variety of interacting processes. Major pyramidal neuron axon circuits functionally connect distant regions of the cortex to enable integrated processing forming the axonal connectome of the networked brain, driven by individual pulse-coded action potentials. Complementing this are waves of continuous potential in the cortical brain tissue indirectly sampled by electrodes on the scalp in the electroencephalogram or EEG and magnetic effects of currents in MEG. While the network view of brain activity is based on individual action potentials and regards the EEG brain waves as just tissue excitation averages, there is increasing evidence of phase coupling between between the two, so that both the discrete action potentials and the continuous tissue potentials are in mutual feedback. The complex interaction of these can be seen in Qasim et al. (2021), Cariani & Baker (2022) and Pinotsis et al. (2023). This leads to two views of brain dynamics the networked view based on the connectome and field theories centred on continuous tissue gradients and the folded tissue anatomy, as exemplified in the independent dynamics of the various EEG bands and spiral and metastable wave states (Roberts et al. 2019, Xu et al. 2023).

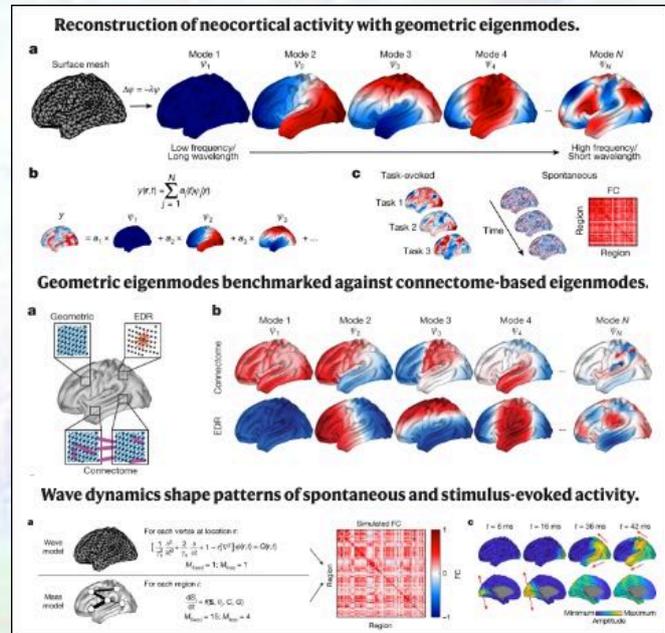

Fig 79b: Comparison of the influences of connectome network based processing, volumetric wave modes in the cortex and exponential distance rule (EDR) networks connectivity and found geometric eigenmodes to be predominant.

Pang et al. (2023) have compared the influence of these two physical features in the outer folds of the cerebral cortex, where most higher-level brain activity occurs — and the connectome, the web of nerves that links distinct regions of the cerebral cortex. Excited neurons in the cerebral cortex can communicate their state of excitation to their immediate neighbours on the surface. But each neuron also has a long axon that connects it to a far away region within or beyond the cortex, allowing neurons to send excitatory messages to distant brain cells. In the past two decades, neuroscientists have painstakingly mapped this web of connections — the connectome — in a raft of organisms, including humans. The brain's neuronal excitation can also come in waves, which can spread across the brain and travel back in periodic oscillations.

They found that the shape of the outer surface was a better predictor of brainwave data than was the connectome, contrary to the paradigm that the connectome has the dominant role in driving brain activity. Predictions from neural field theory, an established framework for modelling large-scale brain activity, suggest that the geometry of the brain may represent a more fundamental constraint on dynamics than complex interregional connectivity. They calculated the modes of brainwave propagation for the cortical surface and for the connectome. As a model of the connectome, they used information gathered from diffusion magnetic resonance imaging (MRI), which images brain anatomy. They then looked at data from more than 10,000 records of functional MRI, which images brain activity based on blood flow. The analysis showed that brainwave modes in the resting brain as well as during a variety of activities — such as during the processing of visual stimuli — were better explained by the surface geometry model than by the connectome. of activities — such as during the processing of visual stimuli — were better explained by the surface geometry model than by the connectome one, the researchers found.

Benjamin Libet (1994), the controversial discoverer of the readiness potential, notes the extreme contrast between the integral nature of conscious experience and the complex localised nature of network-based neurodynamics, leaning towards a field theory as the only plausible explanation:

One of the most mysterious and seemingly intractable problems in the mind-brain relationship is that of the unitary and integrated nature of conscious experience. We have a brain with an estimated 100 billion neurons, each of which may have thousands of interconnections with other neurons. It is increasingly evident that many functions of cerebral cortex are localized. This is not merely true of the primary sensory areas for each sensory modality, of the motor areas which command movement, and of the speech and

language areas, all of which have been known for some time. Many other functions now find other localized representations, including visual interpretations of colour, shape and velocity of images, recognition of human faces, preparation for motor actions, etc. Localized function appears to extend even to the microscopic level within any given area. The cortex appears to be organized into functional and anatomical vertical columns of cells, with discrete interconnections within the column and with other columns near and far, as well as with selective subcortical structures.

In spite of the enormously complex array of localized functions and representations, the conscious experiences related to or elicited by these neuronal features have an integrated and unified nature. Whatever does reach awareness is not experienced as an infinitely detailed array of widely individual events. It may be argued that this amazing discrepancy between particularized neuronal representations and unitary integrated conscious experiences should simply be accepted as part of a general lack of isomorphism between mental and neural events. But that would not exclude the possibility that some unifying process or phenomenon may mediate the profound transformation in question.

The general problem had been recognized by many others, going back at least to Sherrington (1940) and probably earlier. Eccles (in, Popper and Eccles, 1977, p. 362) specifically proposed that the experienced unity comes not from a neurophysiological synthesis but from the proposed integrating character of the self-conscious mind. This was proposed in conjunction with a dualist-interactionist view in which a separate non-material mind could detect and integrate the neuronal activities. Some more monistically inclined neuroscientists have also been arriving at related views, i.e. that integration seems to be best accountable for in the mental sphere even if one views subjective experience as an inner quality of the brain "substrate" (as in "identity theory" or as an emergent property of it. There has been a growing consensus that no single cell or group of cells is likely to be the site of a conscious experience, but rather that conscious experience is an attribute of a more global or distributed function of the brain.

A second apparently intractable problem in the mind-brain relationship involves the reverse direction. There is no doubt that cerebral events or processes can influence, control and presumably "produce" mental events, including conscious ones. The reverse of this, that mental processes can influence or control neuronal ones, has been generally unacceptable to many scientists on (often unexpressed) philosophical grounds. Yet, our own feelings of conscious control of at least some of our behavioural actions and mental operations would seem to provide prima facie evidence for such a reverse interaction, unless one assumes that these feelings are illusory. Eccles (1990; Popper and Eccles, 1977) proposed a dualistic solution, in which separable mental units (called psychons) can affect the probability of presynaptic release of transmitters. Sperry (1952, 1985, 1980) proposed a monistic solution, in which mental activity is an emergent property of cerebral function; although the mental is restrained within a macro-deterministic framework, it can "supervene", though not "intervene", in neuronal activity. However, both views remain philosophical theories, with explanatory power but without experimentally testable formats. As one possible experimentally testable solution to both features of the mind-brain relationship, I would propose that we may view conscious subjective experience as if it were a field, produced by appropriate though multifarious neuronal activities of the brain.

There are a number of field theories of conscious brain dynamics each with their own favoured process.

Joachim Keppler (2018, 2021) presents a field theoretic analysis drawing conscious experiences into the orbit of stochastic electrodynamics (SED) a form of quantum field theory, utilising the conception that the universe is imbued with an all-pervasive electromagnetic background field, the zero-point field (ZPF), which, in its original form, is a homogeneous, isotropic, scale-invariant and maximally disordered ocean of energy with completely uncorrelated field modes and a unique power spectral density. This is basically a stochastic treatment of the uncertainty associated with the quantum vacuum in depictions such as the Feynman approach to quantum electrodynamics (fig 71(e)). The ZPF is thus the multiple manifestations of uncertainty in the quantum vacuum involving virtual photons, electrons and positrons, as well as quarks and gluons, implicit in the muon's anomalous magnetic moment (Borsanyi et al. 2021). In the approach of SED (de la Peña et al. 2020), in which the stochastic aspect corresponds to the effects of the collapse process into the classical limit ⁴², consciousness is represented by the zero point field (ZPF) (Keppler 2018). This provides a basis to discuss the brain dynamics accompanying conscious states in terms of the zero-point field (ZPF):

The aforementioned characteristics and unique properties of the ZPF make one realize that this field has the potential to provide the universal basis for consciousness from which conscious systems acquire their phenomenal qualities. On this basis, I posit that all conceivable shades of phenomenal awareness are woven into the fabric of the background field. Accordingly, due to its disordered ground state, the ZPF can be looked upon as a formless sea of consciousness that carries an enormous range of potentially available phenomenal nuances. Proceeding from this postulate, the mechanism underlying quantum systems has all the makings of a truly fundamental mechanism behind conscious systems, leading to the assumption that conscious systems extract their phenomenal qualities from the phenomenal colour palette immanent in the ZPF.

⁴² The approach of SED is guided by the hypothesis of the existence of the (random) zero-point radiation field, ZPF. This rather more elaborate approach goes through a statistical evolution equation in phase space, to arrive at a description in x-space, in which the dissipative and diffusive terms are seen to bring about a definitive departure from the classical Hamiltonian dynamics.

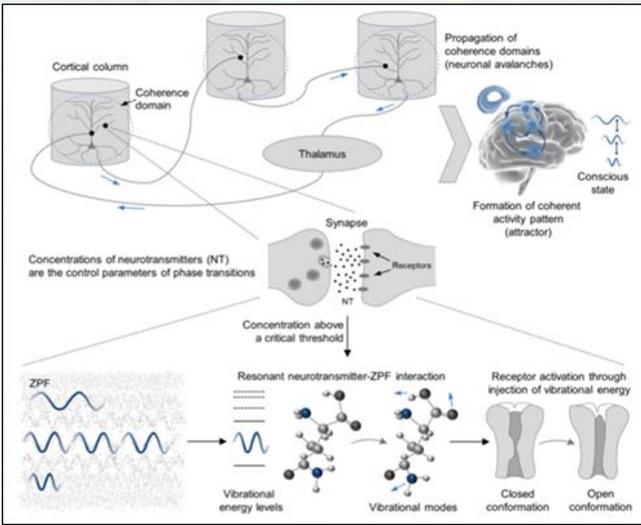

Fig 80: In Keppler's model, the phase transitions underlying the formation of coherent activity patterns (attractors) are triggered by modulating the concentrations of neurotransmitters. When the concentration of neurotransmitter molecules lies above a critical threshold and selected ZPF modes are in resonance with the characteristic transition frequencies between molecular energy levels, receptor activations ensue that drive the emergence of neuronal avalanches. The set of selected ZPF modes that is involved in the formation and stabilisation of an attractor determines the phenomenal properties of the conscious state.

His description demonstrates the kind of boundary conditions in brain dynamics likely to correspond to subjective states and thus provides a good insight into the stochastic uncertainties of brain dynamics of conscious states that would correspond to the subjective aspect, and it even claims to envelop all

possible modes of qualitative subjectivity in the features of the ZPF underlying uncertainty. But it would remain to be established that the ZPF can accommodate all the qualitative variations spanning the senses of sight, sound and smell, which may rather correspond to the external quantum nature of these senses.

The ZPF does not in my view solve the hard problem, because, at face value it is a purely physical manifestation of quantum uncertainty with no subjective manifestation, however Keppler claims to make this link clear as well:

A detailed comparison between the findings of SED and the insights of Eastern philosophy reveals not only a striking congruence as far as the basic principles behind matter are concerned. It also gives us the important hint that the ZPF is a promising candidate for the carrier of consciousness, suggesting that consciousness is a fundamental property of the universe, that the ZPF is the substrate of consciousness and that our individual consciousness is the result of a dynamic interaction process that causes the realization of ZPF information states. ... In that it is ubiquitous and equipped with unique properties, the ZPF has the potential to define a universally standardized substratum for our conscious minds, giving rise to the conjecture that the brain is a complex instrument that filters the varied shades of sensations and emotions selectively out of the all-pervasive field of consciousness, the ZPF (Keppler, 2013).

In personal communication regarding these concerns, Joachim responds as follows:

I understand your reservations about conventional field theories of consciousness. The main problem with these approaches (e.g., McFadden's approach) is that they cannot draw a dividing line between conscious and unconscious field configurations. This leads to the situation that the formation of certain field configurations in the brain is claimed to be associated with consciousness, while the formation of the same (or similar) field configurations in an electronic device would usually not be brought in relation with consciousness. This is what you call quite rightly a common category error. Now, the crucial point is that the ZPF, being the primordial basis of the electromagnetic interaction, offers a way to avoid this category error. According to the approach I propose, the ZPF (with all its field modes) is the substrate of consciousness, everywhere and unrestrictedly. The main difference between conscious and unconscious systems (processes) is their ability to enter into a resonant coupling with the ZPF, resulting in an amplification of selected ZPF modes. Only a special type of system has this ability (the conditions are described in my article). If a system meets the conditions, one must assume that it also has the ability to generate conscious states.

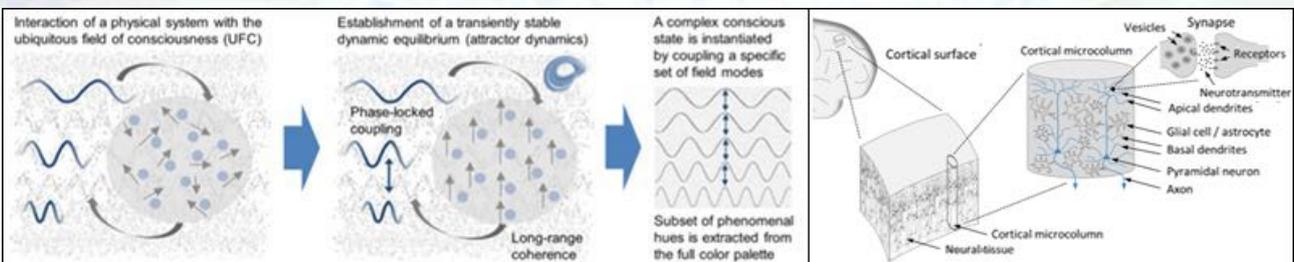

Fig 80b (Left): It is postulated that conscious systems must be equipped with a fundamental mechanism by means of which they are able to influence the basic structure of the ubiquitous field of consciousness (UFC). This requires the interaction of a physical system with the UFC in such a way that a transiently stable dynamic equilibrium, a so-called attractor state characterised by long-range coherence, is established in which the involved field modes enter into a phase-locked coupling. (Right) Cortical column coherence.

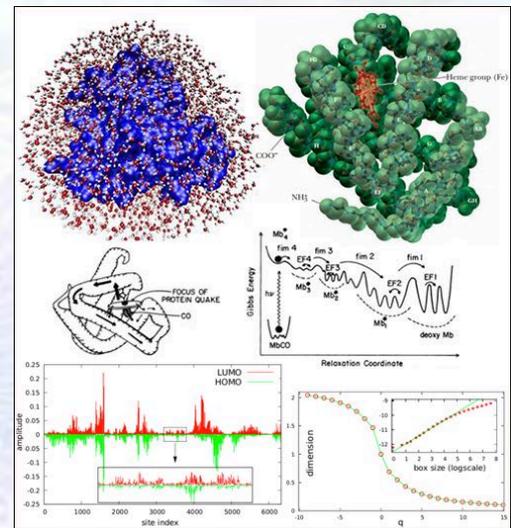

Keppler, and Shani (2020) link this process to a form of cosmopsychism confluent with Symbiotic Existential Cosmology:

The strength of the novel cosmopsychist paradigm presented here lies in the bridging of the explanatory gap the conventional materialist doctrine struggles with. This is achieved by proposing a comprehensible causal mechanism for the formation of phenomenal states that is deeply rooted in the foundations of the universe. More specifically, the sort of cosmopsychism we advocate brings a new perspective into play, according to which the structural, functional, and organizational characteristics of the NCC are indicative of the brain's interaction with and modulation of a UFC. In this respect, the key insights from SED suggest that this field can be equated with the ZPF and that the modulation mechanism is identical with the fundamental mechanism underlying quantum systems, resulting in our conclusion that a coherently oscillating neural cell assembly acquires its phenomenal properties by tapping into the universal pool of phenomenal nuances predetermined by the ZPF.

Keppler (2023) also proposes a model where long-range coherence is developed in the functioning of cortical microcolumns, based on the interaction of a pool of glutamate molecules, with the vacuum fluctuations of the electromagnetic field, involving a phase transition from an ensemble of initially independent molecules toward a coherent state, resulting in the formation of a coherence domain that extends across the full width of a microcolumn.

*John Archibald Wheeler put it greatly, along these lines:
The physics of the vacuum is the real physics – the rest are trivial aspects (Menas Kafatos).*

Fig 81: Molecular biology is a theme and variations on the polar and non-polar properties of organic molecules residing in an aqueous environment. Nucleotide double helices, protein folding and micelle structures, as well as membranes, are all energetically maintained by their surrounding aqueous structures. Water has one of the highest specific heats of all, because of the large number of internal dynamic quantum states. **Myoglobin (Mb)** the oxygen transporting protein in muscle, containing a heme active site illustrates this (Ansari et al. 1984), both in its functionally important movements (fim) and its equilibrium fluctuations invoking fractal energetics between its high and low energy states of Mb and MbCO. This activity in turn is stabilised both by non polar side chains maintaining the aqueous structure and polar side chains interacting with the aqueous environment to form water hydration structures (top left) The hydration shell of myoglobin (blue surface) with 1911 water molecules (CPK model), the approximate number needed for optimal function (Vajda & Perczel 2014). Lower: Here we show that molecules taking part in biochemical processes from small molecules to proteins are critical quantum mechanically. Electronic Hamiltonians of biomolecules are tuned exactly to the critical point of the metal-insulator transition separating the Anderson localized insulator phase from the conducting disordered metal phase. Left: The HOMO/LUMO orbitals for Myoglobin calculated with the Extended Hückel method. Right: Generalized fractal dimensions D_q of the wave functions (Vattay et al. 2015).

Without accepting any materialistic notion of quantum fields being identifiable with subjective consciousness, except as neural correlates of consciousness, this does provide a basis confluent with the description invoked in this article, which uses the infinite number of ground states in quantum field theory, as opposed to quantum mechanics to thermodynamically model memory states and the global amplitude and frequency-modulated binding in the EEG. Karl Pribram (2004) has noted both the similarity of wave coherence interactions as an analogy or manifestation of quantum measurement and the 'holographic' nature of wave potential fluctuations, in the dendritic web:

The holonomic brain theory of quantum consciousness was developed by neuroscientist Karl Pribram initially in collaboration with physicist David Bohm. Pribram suggests these processes involve electric oscillations in the brain's fine-fibered dendritic webs, which are different from the more commonly known action potentials involving axons and synapses. These wave oscillations create interference patterns in which memory is encoded naturally, and the wave function may be analyzed by a Fourier transform. Gabor, Pribram and others noted the similarities between these and the storage of information in a hologram, which can also be analyzed with a Fourier transform.

Coherent wave excitation of pyramidal action potentials has been cited as the basis of correlated potentiation of the glymphatic flow through the brain parenchyma during NREM and particularly REM sleep (Jiang-Xie et al. 2024).

The dissipative quantum model of brain dynamics (Freeman W & Vitiello 2006, 2007, 2016, Capolupo A, Freeman & Vitiello 2013, Vitiello 2015, Sabbadini & Vitiello 2019) provides another field theoretic description. I include below a shortened extract from Freeman & Vitiello (2015), which highlights to me the most outstanding quantum field theoretic description of the neural correlate of consciousness I know of, which also has the support of Freeman's attractor dynamics as illustrated in fig 78, and likewise has similar dual-time properties to the transactional interpretation discussed above, invoking complementary time directed-roles of emergence and imagination:

We began by using classical physics to model the dendritic integration of cortical dynamics with differential equations, ranging in complexity from single positive loops in memory through to simulated intentional behavior (Kozma and Freeman 2009). We identified the desired candidate form in a discrete electrochemical wave packet embedded in the electroencephalogram (EEG), often with the form of a vortex like a hurricane, which carried a spatial pattern of amplitude modulation (AM) that qualified as a candidate for thought content. ... Measurement of scalp EEG in humans (showed that the size and speed of the formation of wave packets were too big to be attributed to the classical neurophysiology of neural networks, so we explored quantum approaches. In order to use dissipative quantum field theory it is necessary to include the impact of brain and body on the environment. Physicists do this conceptually and formally by doubling the variables (Vitiello 1995, 2001, Freeman and Vitiello 2006) that describe dendritic integration in the action-perception cycle. By doing so they create a Double, and then integrate the equations in reverse time, so that every source and sink for the brain-body is matched by a sink or source for the Double, together creating a closed system.

On convergence to the attractor the neural activity in each sensory cortex condenses from a gas-like regime of sparse, disordered firing of action potentials at random intervals to a liquid-like macroscopic field of collective activity. The microscopic pulses still occur at irregular intervals, but the probability of firing is no longer random. The neural mass oscillates at the group frequencies, to which the pulses conform in a type of time multiplexing. The EEG or ECoG (electrocorticogram) scalar field during the liquid phase revealed a burst of beta or gamma oscillation we denoted as a wave packet. Its AM patterns provided the neural correlates of perception and action. The surface grain inferred that the information capacity of wave packets is very high. The intense electrochemical energy of the fields was provided everywhere by the pre-existing trans-membrane ionic concentration gradients.

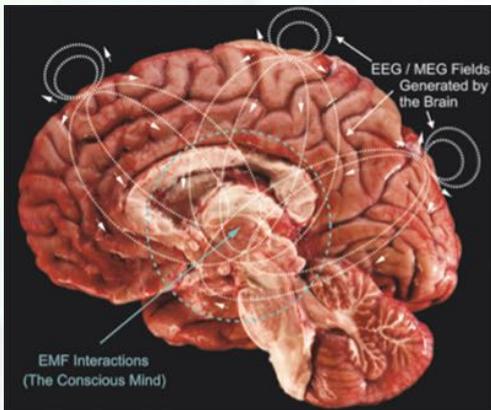

Fig 82: Field theory model of inward projecting electromagnetic fields overlapping in basal brain centres (Maclver 2022).

The theory cites water molecules and the cytosol as the basis for the quantum field description, a position supported at the molecular level by the polarisation of the cytoplasmic medium and all its constituents between aqueous polar and hydrophobic non-polar energetics as illustrated in fig 81. Maclver (2022) has a similar field theoretic model derived from the EEG and MEG. Mandell (2013) also cites chaotic neurodynamics consistent with Freeman's model:

Neurons, glia cells and other physiological units are [treated as] classical objects. The quantum degrees of freedom of the model are associated to the dynamics of the electrical dipoles of the molecules of the basic components of

the system, i.e. biomolecules and molecules of the water matrix in which they are embedded. The coherence of the long-range correlations is of the kind described by quantum field theory in a large number of physical systems, in the standard model of particle physics as well as in condensed matter physics, ranging from crystals to magnets, from superconductive metals to superfluids. The coherent states characterizing such systems are stable in a wide range of temperatures. In physiological terms the field consists of heightened ephaptic⁴³ excitability in an interactive region of neuropil, which creates a dominant focus by which every neuron is sensitized, and to which every neuron contributes its remembrance. In physical terms, the dynamical output of the many-body interaction of the vibrational quanta of the electric dipoles of water molecules and other biomolecules energize the neuropil, the densely compartmentalized tissue of axons, dendrites and glia through which neurons force ionic currents. The boson condensation provides the long-range coherence, which in turn allows and facilitates synaptic communication among neuron populations.

The stages of activation of the quantum field boson condensation correspond closely to stages of the Freeman attractor dynamics investigated empirically in the EEG and ECoG:

We conceive each action-perception cycle as having three stages, each with its neurodynamics and its psychodynamics (Freeman 2015). Each stage has at least one phase transition and may have two or more before the next stage. In the first stage a boson condensation forms a gamma wave packet by a phase transition in each of the primary sensory cortices. Only in stage one a phase transition would occur in a single cortex. In stage two the entorhinal cortex integrates all modalities before making a gestalt. When the boson condensation carrying its AM pattern invades and recruits the amygdala and hypothalamus, we propose that this correlates with awareness of emotion and value with incipient awareness of content. In the second stage a more extended boson condensation forms a larger wave packet in the beta range that extends through the entire limbic system including the entorhinal cortex, which is central in an AM pattern. We believe it correlates with a flash memory unifying the multiple primary percepts into a gestalt, for which the time and place of the subject forming the gestalt are provided by the hippocampus. A third phase transition forms a boson condensation that sustains a global AM pattern, the manifestations of which in the EEG extend over the whole scalp. We propose that the global AM pattern is accompanied by comprehension of the stimulus meaning, which constitutes an up-to-date status summary as the basis for the next intended action.

⁴³ Ephaptic coupling a form of communication within the nervous system involving the coupling of adjacent nerve fibers caused by the exchange of ions between the cells, or as a result of local electrical fields, but distinct from direct communication systems such as synapses.

The dual time representation of the quantum field and its double invokes the key innovative and anticipatory features of conscious imagination:

Open systems require an environment to provide the sink where their waste energy goes, and a source of free energy which feeds them. From the standpoint of the energy flux balance, brains describe the relevant restructured part of the environment using the time-reversed copy of the system, its complement or Double (Vitiello 2001). Where do the hypotheses come from? The answer is: from imagination. In theory the best sources for hypotheses are not memories as they appear in experience, but images mirrored backward in time. The imaginings are not constrained by thermodynamics. The mirror sinks and sources are imagined, not emergent. From this asymmetry we infer that the mirror copy exists as a dynamical system of nerve energy, by which the Double produces its hypotheses and predictions, which we experience as perception, and which we test by taking action. It is the Double that imagines the world outside, free from the shackles of thermodynamic reality. It is the Double that soars.

Johnjoe McFadden (2020) likewise has a theory of consciousness associated with the electromagnetic wave properties of the brain's EM field interacting with the matter properties of "unconscious" neuronal processing. In his own words he summarises his theory as follows:

I describe the conscious electromagnetic information (cemi) field theory which has proposed that consciousness is physically integrated, and causally active, information encoded in the brain's global electromagnetic (EM) field. I here extend the theory to argue that consciousness implements algorithms in space, rather than time, within the brain's EM field. I describe how the cemi field theory accounts for most observed features of consciousness and describe recent experimental support for the theory. ... The cemi field theory differs from some other field theories of consciousness in that it proposes that consciousness — as the brain's EM field — has outputs as well as inputs. In the theory, the brain's endogenous EM field influences brain activity in a feedback loop (note that, despite its 'free' adjective, the cemi field's proposed influence is entirely causal acting on voltage-gated ion channels in neuronal membranes to trigger neural firing.

The lack of correlation between complexity of information integration and conscious thought is also apparent in the common-place observation that tasks that must surely require a massive degree of information integration, such as the locomotory actions needed to run across a rugged terrain, may be performed without awareness but simple sensory inputs, such as stubbing your toe, will override your conscious thoughts. The cemi field theory proposes that the non-conscious neural processing involves temporal (computational) integration whereas operations, such as natural language comprehension, require the simultaneous spatial integration provided by the cemi field. ... Dehaene (2014) has recently described four key signatures of consciousness: (i) a sudden ignition of parietal and prefrontal circuits; (ii) a slow P3 wave in EEG; (iii) a late and sudden burst of high-frequency oscillations; and (iv) exchange of bidirectional and synchronized messages over long distances in the cortex. It is notable that the only feature common to each of these signatures— aspects of what Dehaene calls a 'global ignition' or 'avalanche'—is large endogenous EM field perturbations in the brain, entirely consistent with the cemi field theory.

Jones & Hunt (2023) provide a wide-ranging review of field theories of consciousness culminating in their own favoured theory, combining a panpsychist view concordant with Symbiotic Existential Cosmology although specifically dependent on EM fields as it's key interface. They begin with a critical review of neuronal network approaches to conscious brain function:

Neuroscientists usually explain how our different sensory qualia arise in terms of specialized labeled lines with their own detector fibers and processing areas for taste, vision, and other sensory modes. Photoreceptors thus produce color qualia regardless of whether they are stimulated by light, pressure, or other stimuli. This method is supplemented by detailed comparisons of the fibers within each labeled line. For example, the three color fibers overlap in their response to short, medium, and long wavelengths of incoming light. So across-fiber comparisons of their firing rates help disambiguate which wavelengths are actually present. This longstanding view has arisen from various historical roots. But the overall problem is that these operations are so similar in the visual, tactile, and other sensory modes that it is unclear how these methods can differ enough to account for all the stark differences between color and taste qualia, for example. Another issue (which will be addressed more below) concerns the "hard problem" of why this biological information processing is accompanied by any conscious experience of colors, pains, et cetera.

It might be thought that recently proposed neuron-based neuroscientific theories of consciousness would offer more viable accounts of how different qualia arise. But they rarely do. For example, Global Neuronal Workspace Theory GNWT (e.g., Dehaene and Naccache, 2001; Dehaene, 2014) and Higher-Order Theories (e.g., Rosenthal, 2005) focus on access consciousness—the availability of information for acting, speaking, and reasoning. This access involves attention and thought. But these higher cognitive levels do not do justice to qualia, for qualia appear even at the very lowest levels of conscious cognition in pre-attentive iconic images.

They then explore both integrated information theory and quantum approaches such as Hameroff Penrose, illustrating their limitations:

Integrated Information Theory represents qualia information abstractly and geometrically in the form of a system's "qualia space" (Tononi 2008). This is the space where each axis represents a possible state of the system—a single combination of logic-gate interactions (typically involving synapses). .. IIT's accounts of qualia spaces are far too complex to specify except in the simplest of cases, and no tests for this method of characterizing qualia has yet been proposed, as far as we are aware.

Hameroff and Penrose have not yet addressed how different qualia arise from different quantum states. This latter issue applies to many quantum theories of consciousness. They generally omit mention of how quantum states yield the primary sensory qualia (redness, sweetness, etc.) we are familiar with. For example, Beshkar (2020) contains an interesting QBIT theory of consciousness that attributes qualia to quantum information encoded in maximally entangled states. Yet this information ultimately gets its actual blueness, painfulness, etc. from higher cortical mechanisms criticized above. Another example is Lewtas (2017). He also attributes our primary qualia to quantum levels. Each fundamental particle has some of these various qualia. Synchronized firing by neurons at different frequencies selects from the qualia and binds them to form images. ... The general problem with these highly philosophical qualia theories is that they are hard to evaluate. Their uniting of qualia to quanta is not spelt out in testable detail.

They then outline the difficulties network based neuroscience has dealing with qualia:

Standard neuroscience has not explained well how the brain's separate, distributed visual circuits bind together to support a unified image. This is an aspect of the so-called "binding problem" of how the mind's unity arises ... visual processing uses separate, parallel circuits for color and shape, and it is unclear how these circuits combine to form complete images. Ascending color and shape circuits have few if any synapses for linking their neurons to create colored shapes. Nor do they converge on any central visual area.

- (1) **The coding/correlation problem:** As argued above, the neuronal and computational accounts above have failed to find different information-processing operations among neurons that encode our different qualia.
- (2) **The qualia-integration problem:** Computational accounts also face the problem of explaining how myriad qualia are integrated together to produce overall unified perceptions such as visual images.
- (3) **The hard problem:** In addition to the two empirical problems above, computational accounts face a hard, metaphysical problem. Why are neural events accompanied by any qualia at all?

They then explore how field theories can address these fundamental issues:

EM field approaches to minds have offered new theories of qualia and consciousness, some of which are testable. These electromagnetic approaches seat consciousness primarily in the various complex EM fields generated by neurons, glia and the rest of the brain and body. ... These EM field approaches are proliferating because they draw on considerable experimental evidence and withstand past criticisms from standard neuroscience. For example, they have explained the unity of consciousness in terms of the physical unity (by definition) of EM fields—in contrast to the discrete nature of neurons and their synaptic firing. In the last two decades, they have also offered explanations of how neural EM activity creates different qualia.

Pockett's (2000) theory of qualia is an important landmark in EM field theories of mind. It is rooted in extensive experimental evidence, makes testable predictions, and is strongly defended against critics. If Kohler, Libet, Eccles, and Popper helped establish the EM field approach to minds, Susan Pockett has arguably done more to develop it than anyone else—except for perhaps Johnjoe McFadden. ... Pockett's basic claim is that "consciousness is identical with certain spatiotemporal patterns in the electromagnetic field" (*ibid.*, pp. vi, 109, 136–7). Her evidence comes mainly from extensive EEG and MEG studies of neural electromagnetic fields. They show correlations between sensory qualia and field patterns. For example, EEG studies by Freeman (1991) show that various odors (e.g., from bananas or sawdust) correlate with specific spatial patterns distributed across mammalian olfactory areas.

McFadden's (202b) theory says that information is conscious at all levels, which seems to entail a form of panpsychism (McFadden, 2002b). The "discrete" consciousness of elementary particles is limited and isolated. But as particles join into a field, they form a unified "field" consciousness. As these fields affect motor neurons, the brain's consciousness is no longer an epiphenomenon, for its volition can communicate with the world. This level of "access" consciousness serves as a global workspace where specialized processors compete for access to volition's global, conscious processes. McFadden rejects popular views that minds are just ineffectual epiphenomena of brain activity. Instead, field–nerve interactions are the basis of free will. The conscious field is deterministic, yet it is free in that it affects behavior instead of being epiphenomenal (McFadden, 2002a,b). This treats determinism as compatible with free will construed as self-determination.

They postpone the hard problem and focus on the first two above:

- (1) **The coding/correlation problem:** What different EM-field activities encode or correlate with the various qualia? Both field theories above face difficulties here.
- (2) **The qualia-integration problem:** How do EM fields integrate myriad qualia to form (for example) unified pictorial images? Here field theories seem quite promising in their ability to improve upon standard neuroscience.

They then cite three emergent field theories which have sought to address the outstanding problems faced by the field theories already discussed:

Ward and Guevara (2022) localize qualia in the fields generated by a particular part of the brain. Their intriguing thesis is that our consciousness and its qualia are based primarily on structures in thalamic EM fields which serve to model environmental and bodily information in ways relevant to controlling action. Ward and Guevara argue that the physical substrate of consciousness is limited to strong neural EM fields where synchronously firing neurons reinforce each other's information in a manner which is also integrated and complex. Finally, local, nonsynchronous fields can be canceled out in favor of a dominant field that synchronously and coherently represents all the information from our senses, memories, emotions, et cetera. For these reasons, Ward and Guevara believe that

fields are better candidates than neurons and synaptic firing for the primary substrate of consciousness. ... they cite four reasons for ascribing consciousness to the thalamus. (1) We are not conscious of all sensory computations, just their end result, which involves the thalamic dynamic core. (2) Thalamic dysfunctions (but not necessarily cortical dysfunctions) are deeply involved in nonconsciousness conditions such as anesthesia, unresponsive wakefulness syndrome, and anoxia. (3) The thalamus is a prime source and controller of synchronization (in itself and in cortex), which is also associated with consciousness. (4) The thalamus (especially its DM nucleus Ouhaz et al. 2018) is ideally suited for the integrative role associated with consciousness, for cortical feedbacks seem to download cortical computations into thalamus. ... These lines of evidence indicate that while cortex computes qualia, thalamus displays qualia.

Another author who attributes qualia to fundamental EM activity is Bond (2023). This clear, succinct paper explains that quantum coherence involves the entanglement of quanta within energy fields, including the EM fields generated by neurons. Neural matter typically lacks this coherence because the haphazard orientation of quantum spins in the matter creates destructive interference and decoherence. Bond proposes the novel idea that firing neurons generate EM fields that can flow through nearby molecular structures and entangle with their atoms. This coherence produces our perceptions. The different subjective feelings of these perceptions come from different hybrids or mixtures of the fields' wavelengths as they vibrate or resonate. ... On a larger scale, this coherence ties into the well-known phase-locking of corticothalamic feedback loops. Together, they produce the holism or unity of consciousness. This combination of coherent, phase-locked feedback loops and coherent, entangled wave-particles in EM fields is called by Bond a "coherence field." It is investigated by his Coherence Field Theory (CFT).

Finally, as joint authors, they elucidate their favoured theory GRT arising from their independent research:

Another approach to the Qualia Problem is Hunt and Schooler's **General Resonance Theory (GRT)**, which is grounded in a panpsychist framework. GRT assumes that all matter is associated with at least some capacity for phenomenal consciousness (this is called the "panpsychism axiom"), but that consciousness is extremely rudimentary in the vast majority of cases due to a lack of physical complexity mirrored by the lack of mental complexity. The EM fields associated with all baryonic matter (i.e., charged particles) are thought to be the primary seat of consciousness simply because EM fields are the primary force at the scale of life (strong and weak nuclear fields are operative at scales far smaller and gravity is operative mostly at scales far larger). Accordingly, GRT is applicable to all physical structures and as a theory is not limited only to neurobiological or even biological structures (Hunt and Schooler, 2019).

GRT suggests that resonance (similar but not synonymous with synchronization and coherence) of various types is the key mechanism by which the basic constituents of consciousness, when in sufficient proximity, combine into more complex types of consciousness. This is the case because shared resonance allows for phase transitions in the speed and bandwidth of information exchange to occur at various organizational levels, allowing previously disordered systems to self-organize and thus become coherent by freely sharing information and energy.

Qualia, in GRT, are synonymous with consciousness, which is simply subjective experience:

Jones (2017, 2019), a coauthor of the current paper, has developed an EM-field theory of qualia. Like other field theories, it attributes qualia and images to neural EM-field patterns (and probably the EM-charged matter emitting the fields). Yet these are not the coded images of computational field theories that are based on information processing. Instead, in his theory images actually reside in conscious, pictorial form within the EM fields of neural maps. This is a neuroelectrical, pure panpsychist theory of mind (NP). The "pure panpsychism" says that everything (not just EM) is comprised purely of consciousness. NP addresses the hard problem, qualia-integration problem, and qualia coding/correlation problem in the following ways.

- (1) **The hard problem:** How are qualia metaphysically related to brains and computations? In NP, consciousness and its qualia are the hidden nature of observable matter and energy. We are directly aware of our inner conscious thoughts and feelings. Yet we are just indirectly aware of the observable, external world through reflected light, instruments, sense organs, et cetera.
- (2) **The qualia coding/correlation problem:** How do our various qualia arise? Yet there is now growing evidence that different qualia correlate with different electrically active substances in cellular membranes found in sensory and emotional circuits. These substances are the membranes' ion-channel proteins and associated G-protein-coupled receptors (GPCRs). For example, the different primary colors correlate with different OPN1 GPCRs ... oxytocin and vasopressin receptor proteins correlate with feelings of love, estrogen and testosterone receptors correlate with lust, the endorphin receptor correlates with euphoria, and the adrenaline receptor correlates with vigilance.
- (3) **The qualia-integration problem:** First, how do various qualia unify together into an overall whole? Second, how specifically do qualia join point by point to form pictorial images? In NP's field theory, active circuits create a continuous EM field between neurons that pools their separate, atomized consciousness. This creates a unified conscious mind along brain circuits (with the mind itself residing in the field and perhaps in the charged matter creating the field). This unity is strongest around the diffuse ion currents that run along (and even between) neuronal circuits. It is very strong among well-aligned cortical cells that fire together coherently.

In conclusion ... Consciousness is characterized mainly by its privately experienced qualities (qualia). Standard, computation-based and synapse-based neuroscience have serious difficulties explaining them. ... field theories have improved in key ways upon standard neuroscience in explaining qualia. But this progress is sometimes tentative—it awaits further evidence and development.

Summarising the state of play, we have two manifestations of consciousness at the interface with objective physical description, (a) **the hard problem of consciousness** and (b) **the problem of quantum measurement**, both of which are in continual debate. Together these provide complementary windows on the abyss in the scientific description and a complete solution of existential cosmology that we shall explore in this article.

Neural Nets versus Biological Brains

Steven Grossberg is recognised for his contribution to ideas using nonlinear systems of differential equations such as laminar computing, where the layered cortical structures of mammalian brains provide selective advantages, and for complementary computing, which concerns the idea that pairs of parallel cortical processing streams compute complementary properties in the brain, each stream having complementary computational strengths and weaknesses, analogous to physical complementarity in the uncertainty principle. Each can possess multiple processing stages realising a hierarchical resolution of “uncertainty”, which here means that computing one set of properties at a given stage prevents computation of a complementary set of properties at that stage.

The primary intuition behind the ART model is that object identification and recognition generally occur as a result of the interaction of 'top-down' observer expectations with 'bottom-up' sensory information. The model postulates that 'top-down' expectations take the form of a memory template or prototype that is then compared with the actual features of an object as detected by the senses. This comparison gives rise to a measure of category belongingness. As long as this difference between sensation and expectation does not exceed a set threshold called the 'vigilance parameter', the sensed object will be considered a member of the expected class. The system thus offers a solution to the 'plasticity/stability' problem, i.e. the problem of acquiring new knowledge without disrupting existing knowledge that is also called incremental learning.

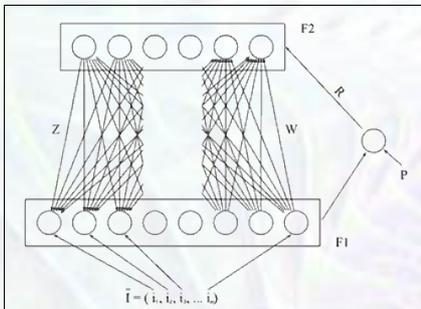

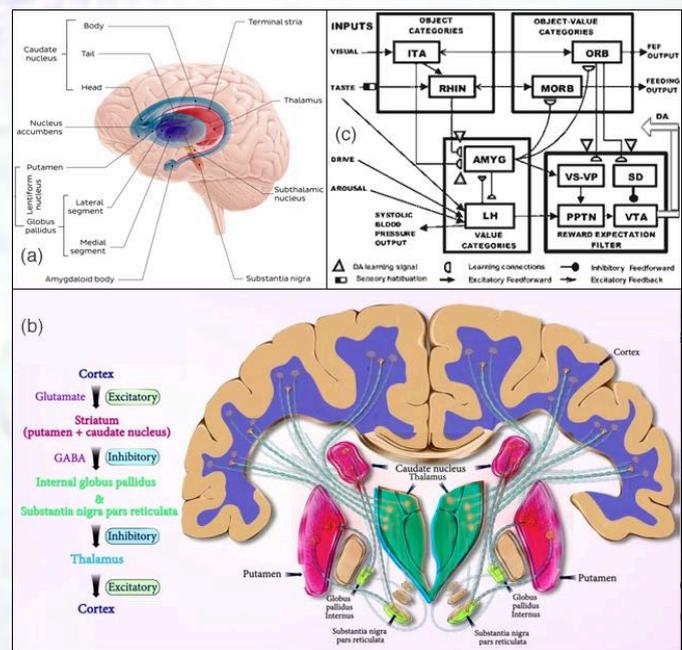

Fig 82b: The basic ART structure.

“Conscious Mind, Resonant Brain” (Grossberg 2021) provides a panoramic model of the brain, from neural networks to network representations of conscious brain states. In so doing, he presents a view based on resonant non-linear systems, which he calls adaptive resonance theory (ART), in which a subset of “resonant” brain states are associated with conscious experiences. While I like his use of non-linear dynamics, ART is a structural abstract neural network model and not what I as a mathematical dynamicist conceive of as “resonance”, compared with the more realistic GNW, or global neuronal workspace model.

Fig 83: Brain centres involved in intentional behaviour and subjectively conscious physical volition: (a) The cortex overlaying the basal ganglia, thalamus and amygdala and substantia nigra involved in planned action, motivation and volition. (b) The interactive circuits in the cortex, striatum and thalamus facilitating intentional motor behaviour. (c) The Motivator model clarifies how the basal ganglia and amygdala coordinate their complementary functions in the learning and performance of motivated acts. Brain areas can be divided into four regions that process information about conditioned stimuli (CSs) and unconditioned stimuli (USs). (a) Object Categories represent visual or gustatory inputs, in anterior inferotemporal (ITA) and rhinal (RHIN) cortices; (b) Value Categories represent the value of anticipated outcomes on the basis of hunger and satiety inputs, in amygdala (AMYG) and lateral hypothalamus (LH); (c) Object-Value Categories resolve the value of competing perceptual stimuli in medial (MORB) and lateral (ORB) orbitofrontal cortex; and (d) the Reward Expectation Filter in the basal ganglia detects the omission or delivery of rewards using a circuit that spans ventral striatum (VS), ventral pallidum (VP), striosomes of the striatum, the pedunculopontine nucleus (PPTN) and midbrain dopaminergic neurons of the SNc/VTA (substantia nigra pars compacta/ventral tegmental area). The network model connecting brain regions is consistent with both quantum and classical approaches and in no way eliminates subjective conscious volition from having an autonomous role. All it implies is that conscious volition arises from an evolved basis in these circuit relationships in mammals.

The work shows in detail how and why multiple processing stages are needed before the brain can construct a complete and stable enough representation of the information in the world with which to predict environmental challenges and thus control effective behaviours. Complementary computing and hierarchical resolution of uncertainty overcome these problems until perceptual representations that are sufficiently complete, context-sensitive, and stable can be formed. The brain regions where these representations are completed are different for seeing, hearing, feeling, and knowing.

His proposed answer is that a resonant state is generated that selectively “lights up” these representations and thereby renders them conscious. These conscious representations can then be used to trigger effective behaviours:

*My proposed answer is: A resonant state is generated that selectively “lights up” these representations and thereby renders them conscious. These conscious representations can then be used to trigger effective behaviors. Consciousness hereby enables our brains to prevent the noisy and ambiguous information that is computed at earlier processing stages from triggering actions that could lead to disastrous consequences. Conscious states thus provide **an extra degree of freedom** whereby the brain ensures that its interactions with the environment, whether external or internal, are as effective as possible, given the information at hand.*

He addresses the hard problem of consciousness in its varying aspects:

As Chalmers (1995) has noted: “The really hard problem of consciousness is the problem of experience. When we think and perceive, there is a whirl of information-processing, but there is also a subjective aspect. As Nagel (1974) has put it, there is something it is like to be a conscious organism. This subjective aspect is experience. When we see, for example, we experience visual sensations: the felt quality of redness, the experience of dark and light, the quality of depth in a visual field. ... Even after we have explained the functional, dynamical, and structural properties of the conscious mind, we can still meaningfully ask the question, Why is it conscious? There seems to be an unbridgeable explanatory gap between the physical world and consciousness. All these factors make the hard problem hard. ... Philosophers vary passionately in their views between the claim that no Hard Problem remains once it is explained how the brain generates experience, as in the writings of Daniel Dennett, to the claim that it cannot in principle be solved by the scientific method, as in the writings of David Chalmers. See the above reference for a good summary of these opinions.

Grossberg demonstrates that, over and above information processing, our brains sometimes go into a context-sensitive resonant state that can involve multiple brain regions. He explores experimental evidence that “all conscious states are resonant states” but not vice versa. Showing that, since not all brain dynamics are “resonant”, consciousness is not just a “whirl of information-processing”:

When does a resonant state embody a conscious experience? “Why is it conscious”? And how do different resonant states support different kinds of conscious qualia? The other side of the coin is equally important: When does a resonant state fail to embody a conscious experience? Advanced brains have evolved in response to various evolutionary challenges in order to adapt to changing environments in real time. ART explains how consciousness enables such brains to better adapt to the world’s changing demands.

Grossberg is realistic about the limits on a scientific explanation of the hard problem:

It is important to ask: How far can any scientific theory go towards solving the Hard Problem? Let us suppose that a theory exists whose neural mechanisms interact to generate dynamical states with properties that mimic the parametric properties of the individual qualia that we consciously experience, notably the spatio-temporal patterning and dynamics of the resonant neural representations that represent these qualia. Suppose that these resonant dynamical states, in addition to mirroring properties of subjective reports of these qualia, predict properties of these experiences that are confirmed by psychological and noninvasive neurobiological experiments on humans, and are consistent with psychological, multiple-electrode neurophysiological data, and other types of neurobiological data that are collected from monkeys who experience the same stimulus conditions.

He then develops a strategy to move beyond the notion of the neural correlate of consciousness (Crick & Koch 1990), claiming these states are actually the physical manifestation of the conscious state:

Given such detailed correspondences with experienced qualia and multiple types of data, it can be argued that these dynamical resonant states are not just “neural correlates of consciousness” that various authors have also discussed, notably David Chalmers and Christof Koch and their colleagues. Rather, they are mechanistic representations of the qualia that embody individual conscious experiences on the psychological level. If such a correspondence between detailed brain representations and detailed properties of conscious qualia occurs for a sufficiently large body of psychological data, then it would provide strong evidence that these brain representations create and support these conscious experiences. A theory of this kind would have provided a linking hypothesis between brain dynamics and the conscious mind. Such a linking hypothesis between brain and mind must be demonstrated before one can claim to have a “theory of consciousness”.

However he then delineates the claim that this is the most complete scientific account of subjective experience possible, while conceding that it may point to a cosmological problem akin those in relativity and quantum theory:

If, despite such a linking hypothesis, a philosopher or scientist claims that, unless one can “see red” or “feel fear” in a theory of the Hard Problem, then it does not contribute to solving that problem, then no scientific theory can ever hope to solve the Hard Problem. This is true because science as we know it cannot do more than to provide a mechanistic theoretical description of the dynamical events that occur when individual conscious qualia are experienced. However, as such a principled, albeit incrementally developing, theory of consciousness becomes available, including increasingly detailed psychological, neurobiological, and even biochemical processes in its explanations, it can dramatically shift the focus of discussions about consciousness, just as relativity theory transformed discussions of space and time, and quantum theory of how matter works. As in quantum theory, there are measurement limitations in understanding our brains.

Although he conceives of brain dynamics as being poised just above the level of quantum effects in vision and hearing, Grossberg sees brains as a new frontier of scientific discovery subject to the same principles of complementarity and uncertainty as arise in quantum physics:

Since brains form part of the physical world, and interact ceaselessly with it to adapt to environmental challenges, it is perhaps not surprising that brains also obey principles of complementarity and uncertainty. Indeed, each brain is a measurement device for recording and analyzing events in the physical world. In fact, the human brain can detect even small numbers of the photons that give rise to percepts of light, and is tuned just above the noise level of phonons that give rise to percepts of sound.

Complementarity and uncertainty principles also arise in physics, notably in quantum mechanics. Since brains form part of the physical world, and interact ceaselessly with it to adapt to environmental challenges, it is perhaps not surprising that brains also obey principles of complementarity and uncertainty. Indeed, each brain is a measurement device for recording and analyzing events in the physical world. In fact, the human brain can detect even small numbers of the photons that give rise to percepts of light, and is tuned just above the noise level of phonons that give rise to percepts of sound.

The Uncertainty Principle identified complementary variables, such as the position and momentum of a particle, that could not both be measured with perfect precision. In all of these theories, however, the measurer who was initiating and recording measurements remained out- side the measurement process. When we try to understand the brain, this is no longer possible. The brain is the measurement device, and the process of understanding mind and brain is the study of how brains measure the world. The measurement process is hereby brought into physical theory to an unprecedented degree.

Such neurosystem models provide key insights into how processes associated with intentional acts and the reinforcement of sensory experiences through complementary adaptive networks, model the neural correlate of conscious volitional acts and their smooth motor execution in the world at large. As they stand, these are still classical objective models that do not actually invoke conscious volition as experienced, but they do provide deep insight into the brain's adaptive processes accompanying subjective conscious volition.

The brain's universal measurement process can be expected to have a comparable impact on future science, once its implications are more broadly understood. Brain dynamics operate, however, above the quantum level, although they do so with remarkable efficiency, responding to just a few photons of light in the dark, and to faint sounds whose amplitude is just above the level of thermal noise in otherwise quiet spaces. Knowing more about how this exquisite tuning arose during evolution could provide important new information about the design of perceptual systems, no less than about how quantum processes interface with processes whose main interactions seem to be macroscopic.

Grossberg sees the brain as presenting new issues for science as measurement devices confounding their separation between measured effect and the observer making a quantum measurement:

Since brains are also universal measurement devices, how do they differ from these more classical physical ideas? I believe that it is the brain's ability to rapidly self-organize, through development and life-long learning, that sets it apart from previous physical theories. The brain thus represents a new frontier in measurement theory for the physical sciences, no less than the biological sciences. It remains to be seen how physical theories will develop to increasingly incorporate concepts about the self-organization of matter, and how these theories will be related to the special case of brain self-organization.

Experimental and theoretical evidence will be summarized in several chapters in support of the hypothesis that principles of complementarity and uncertainty that are realized within processing streams, better explain the brain's functional organization than concepts about independent modules. Given this conclusion, we need to ask: If the brain and the physical world are both organized according to such principles, then in what way is the brain different from the types of physical theories that are already well-known? Why haven't good theoretical physicists already “solved” the brain using known physical theories?

In discussing the hierarchical feedback of the cortex and basal ganglia and the limbic system, Grossberg (2015) fluently cites both consciousness and volition as adaptive features of the brain as a self-organising system:

The basal ganglia control the gating of all phasic movements, including both eye movements and arm movements. Arm movements, unlike eye movements, can be made at variable speeds that are under volitional basal ganglia control. Arm movements realize the Three S's of Movement Control; namely, Synergy, Synchrony, and Speed. ... Many other brain processes can also be gated by the basal ganglia, whether automatically or through conscious volition. Several of these gating processes seem to regulate whether a top-down process subliminally primes or fully activates its target cells. As noted in Section 5.1, the ART Matching Rule enables the brain to dynamically stabilize learned memories using top-down attentional matching.

Such a volitionally-mediated shift enables top-down expectations, even in the absence of supportive bottom-up inputs, to cause conscious experiences of imagery and inner speech, and thereby to enable visual imagery, thinking, and planning activities to occur. Thus, the ability of volitional signals to convert the modulatory top-down priming signals into suprathreshold activations provides a great evolutionary advantage to those who possess it.

My critique, which this is clear and simple, is that these designs remove such a high proportion of the key physical principles involved in biological brain function that they can have no hope of modelling subjective consciousness or volition, despite the liberal use of these terms in the network designs, such as the basal ganglia as gateways. Any pure abstract neural net model, however much it adapts to "resonate" with biological systems is missing major fundamental formative physical principles of how brains actually work.

These include:

- (a) The fact that biological neural networks are both biochemical and electrochemical in two ways (1) all electrochemical linkages, apart from gap junctions, work through the mediation of biochemical neurotransmitters and (2) the internal dynamics of individual neurons and glia are biochemical, not electrochemical.
- (b) The fact that the electrochemical signals are dynamic and involve sophisticated properties including both (1) unstable dynamics at the edge of chaos and (2) phase coherence tuning between continuous potential gradients and action potentials.
- (c) They involve both neurons and neuroglia working in complementary relationship.
- (d) They involve developmental processes of cell migration determining the global architecture of the brain including both differentiation by the influence of neurotransmitter type and chaotic excitation in early development.
- (e) This neglects the fact that evolution of biological brains as neural networks is built on the excitatory neurotransmitter-driven social signalling and quantum sentience of single celled eucaryotes, forming an intimately coupled society of amoeba-flagellate cells communicating by the same neurotransmitters as in single-celled eucaryotes, so these underlying dynamics are fundamental and essential to biological neural net functionality.

Everything from simple molecules such as ATP acting as the energy currency of the cell, through protein folding, to enzymes involve quantum effects, such as tunnelling at active sites, and ion channels are at the same level.

It is only a step from there to recognising that such biological processes are actually fractal non-IID (not identically independently-distributed quantum processes, not converging to the classical, in the light of Gallego & Dakić (2021), because their defining contexts are continually evolving, to thus provide a causally open view of brain dynamics, in which the extra degree of freedom provided by consciousness, that complements objective physical computation, arises partly through quantum uncertainty itself, in conscious volition becoming subjectively manifest, and ensuring survival under uncertain environmental threats.

However, this is not just a rational or mechanistically causal process. We evolved from generation upon generation of organisms surviving existential threats in the wild, which were predominantly solved by lightning fast hunch and intuition, and never by rational thought alone, except recently and all too briefly in our cultural epoch.

The great existential crises have always been about surviving environmental threats which are not only computationally intractable due to exponentiating degrees of freedom, but computationally insoluble because they involve the interaction of live volitional agents, each consciously violating the rules of the game.

Conscious volition evolved to enable subjective living agents to make hunch-like predictions of their own survival in contexts where no algorithmic or deterministic process, including the nascent parallelism of the cortex, limbic system and basal ganglia that Steve Grossberg has drawn attention to, could suffice, other than to define boundary conditions on conscious choices of volitional action. Conscious intentional will, given these constraints, remained the critical factor, complementing computational predictivity generated through non-linear dynamics, best predicting survival of a living organism in the quantum universe, which is why we still possess it.

When we come to the enigma of subjective conscious anticipation and volition under survival threats, these are clearly, at the physiological level, the most ancient and most strongly conserved. Although the brains of vertebrates, arthropods and cephalopods show vast network differences, the underlying processes generating consciousness remain strongly conserved to the extent that baby spiders display clear REM features during sleep despite having no obvious neural net correspondence. While graded membrane excitation is universal to all eucaryotes and shared by human phagocytes and amoeba, including the genes for the poisons used to kill bacteria, the action potential appears to have evolved only in flagellate eucaryotes, as part of the flagellar escape response to existential threat, later exemplified by the group flagellation of our choano-flagellate ancestor colonies.

Just as circuit design models can have predictive value, so does subjective conscious volition of the excitable eucaryote cell have clear survival value in evolution and hence predictive power of survival under existential threat, both in terms of arbitrary sensitivity to external stimuli at the quantum level and neurotransmitter generated social decision-making of the collective organism. Thus the basis of what we conceive of as subjective conscious volition is much more ancient and longer and more strongly conserved than any individual network model of the vertebrate brain and underlies all attempts to form realistic network models.

All brains are thus intimate societies of dynamically-coupled excitable cells (neurons and glia) communicating through these same molecular social signalling pathways that social single celled eucaryotes use. Both strategic intelligence and conscious volition as edge-of-chaos membrane excitation in global feedback thus arose long before brains and network designs emerged.

Since our cultural emergence, *Homo sapiens* has been locked in a state of competitive survival against its own individuals, via Machiavellian intelligence, but broadly speaking, rationality – dependence on rational thought processes as a basis for adaption – just brings us closer to the machine learning of robots, rather than conscious volition. Steve’s representation of the mechanical aspects in the basal ganglia in Grossberg (2015) gives a good representation of how living neurosystems adaptively evolve to make the mechanical aspect of the neural correlate of conscious volition possible, but it says little about how we actually survive the tiger’s pounce, let alone the ultimate subtleties of human political intrigue, when the computational factor are ambiguous.. Likewise decision theory or prospect theory, as noted in Wikipedia, tells us only a relatively obvious asymmetric sigmoidal function describing how risk aversion helps us survive, essentially because being eaten rates more decisively in the cost stakes than any single square meal as a benefit.

Because proving physical causal closure of the universe in brain dynamics is impossible to practically achieve in the quantum universe, physical materialism is itself not a scientific concept, so all attempts to model and understand conscious volition remain open and will continue to do so. The hard problem of consciousness is not a division between science and philosophy as Steve suggests in his (2021) book, but our very oracle of cosmological existence.

Epiphenomenalism, Interactionism, Conscious Volition and Free Will

Thomas Kuhn (1922–1996) is perhaps the most influential philosopher of science of the twentieth century. His book “The Structure of Scientific Revolutions” (Kuhn 1962) is one of the most cited academic books of all time. A particularly important part of Kuhn’s thesis focuses upon the consensus on exemplary instances of scientific research. These exemplars of good science are what Kuhn refers to when he uses the term ‘paradigm’ in a narrower sense. He cites Aristotle’s analysis of motion, Ptolemy’s computations of planetary positions, Lavoisier’s application of the balance, and Maxwell’s mathematisation of the electromagnetic field as paradigms (ibid, 23). According to Kuhn the development of a science is not uniform but has alternating ‘normal’ and ‘revolutionary’ (or ‘extraordinary’) phases in which paradigm shifts occur.

Rejecting a teleological view of science progressing towards the truth, Kuhn favours an evolutionary view of scientific progress (1962 170–3). The evolutionary development of an organism might be seen as its response to a challenge set by its environment. But that does not imply that there is some ideal form of the organism that it is evolving towards. Analogously, science improves by allowing its theories to evolve in response to puzzles and progress is measured by its success in solving those puzzles; it is not measured by its progress towards to an ideal true theory. While evolution does not lead towards ideal organisms, it does lead to greater diversity of kinds of organism. This is the basis of a Kuhnian account of specialisation in science in which the revolutionary new theory that succeeds in replacing another

that is subject to crisis, may fail to satisfy all the needs of those working with the earlier theory. One response to this might be for the field to develop two theories, with domains restricted relative to the original theory (one might be the old theory or a version of it).

Free will is the notion that we can make real choices which are partially or completely independent of antecedent conditions – "the power of acting without the constraint of necessity or fate; the ability to act at one's own discretion", in the context of the given circumstances. Determinism denies this and maintains that causation is operative in all human affairs. Increasingly, despite the discovery of quantum uncertainty, scientists argue that their discoveries challenge the existence of free will. Studies indicate that informing people about such discoveries can change the degree to which they believe in free will and subtly alter their behaviour, leading to a social erosion of human agency, personal and ethical responsibility.

Philosophical analysis of free will divides into two opposing responses. Incompatibilists claim that free will and determinism cannot coexist. Among incompatibilists, metaphysical libertarians, who number among them Descartes, Bishop Berkeley and Kant, argue that humans have free will, and hence deny the truth of determinism. Libertarianism holds onto a concept of free will that requires the agent to be able to take more than one possible course of action under a given set of circumstances, some arguing that indeterminism helps secure free will, others arguing that free will requires a special causal power, agent-causation. Instead, compatibilists argue that free and responsible agency requires the capacities involved in self-reflection and practical deliberation; free will is the ability to make choices based on reasons, along with the opportunity to exercise this ability without undue constraints (Nadelhoffer et al. 2014). This can make rational acts or decisions compatible with determinism.

Our concern here is thus not with responsible agency, which may or may not be compatible with determinism, but affirming the existence of agency not causally determined by physical processes in the brain. Epiphenomenalists accept that subjective consciousness exists, as an internal model of reality constructed by the brain to give a global description of the coherent brain processes involved in perception attention and cognition, but deny the volitional will over our actions that is central to both reasoned and creative physical actions. This invokes a serious doubt that materialistic neuroscience can be in any way consistent with any form of consciously conceived ethics, because invoking moral or ethical reasoning is reduced to forms of aversive conditioning, consistent with behaviouralism, and Pavlov's dogs, subjectively rationalised by the subject as a reason. This places volition as being a delusion driven by evolutionary compensation to mask the futility of any subjective belief in organismic agency over the world.

Defending subjective volitional agency thus depends centrally on the innovative ability of the subjective conscious agent to generate actions which lie outside the constraints of determined antecedents, placing a key emphasis on creativity and idiosyncrasy, amid physical uncertainty, rather than cognitive rationality, as reasons are themselves subject to antecedents.

Bob Doyle notes that in the first two-stage model of free-will, William James (1884) proposed that indeterminism is the source for what James calls "alternative possibilities" and "ambiguous futures." The chance generation of such alternative possibilities for action does not in any way limit his choice to one of them. For James chance is not the direct cause of actions. James makes it clear that it is his choice that "grants consent" to one of them. In 1884, James asked some Harvard Divinity School students to consider his choice for walking home after his talk:

"What is meant by saying that my choice of which way to walk home after the lecture is ambiguous and matter of chance?...It means that both Divinity Avenue and Oxford Street are called but only one, and that one either one, shall be chosen."

James was thus the first thinker to enunciate clearly a two-stage decision process, with chance in a present time of random alternatives, leading to a choice which grants consent to one possibility and transforms an equivocal ambiguous future into an unalterable and simple past. There is a temporal sequence of undetermined alternative possibilities followed by an adequately determined choice where chance is no longer a factor. James also asked the students to imagine his actions repeated in exactly the same circumstances, a condition which is regarded today as one of the great challenges to libertarian free will. He anticipates much of modern physical theories of multiple universes:

Imagine that I first walk through Divinity Avenue, and then imagine that the powers governing the universe annihilate ten minutes of time with all that it contained, and set me back at the door of this hall just as I was before the choice was made. Imagine then that, everything else being the same, I now make a different choice and traverse Oxford Street. You, as passive spectators, look on and see the two alternative universes,--one of them with me walking through Divinity Avenue in it, the other with the same me

walking through Oxford Street. Now, if you are determinists you believe one of these universes to have been from eternity impossible: you believe it to have been impossible because of the intrinsic irrationality or accidentality somewhere involved in it. But looking outwardly at these universes, can you say which is the impossible and accidental one, and which the rational and necessary one? I doubt if the most ironclad determinist among you could have the slightest glimmer of light on this point.

Henri Poincaré speculated on how his mind worked when solving mathematical problems. He had the critical insight that random combinations and possibilities are generated, some in an unconsciously, then they are selected among, perhaps initially also by an unconscious process, but then by a definite conscious process of validation:

It is certain that the combinations which present themselves to the mind in a kind of sudden illumination after a somewhat prolonged period of unconscious work are generally useful and fruitful combinations... all the combinations are formed as a result of the automatic action of the subliminal ego, but those only which are interesting find their way into the field of consciousness... A few only are harmonious, and consequently at once useful and beautiful, and they will be capable of affecting the geometrician's special sensibility I have been speaking of; which, once aroused, will direct our attention upon them, and will thus give them the opportunity of becoming conscious... In the subliminal ego, on the contrary, there reigns what I would call liberty, if one could give this name to the mere absence of discipline and to disorder born of chance.

Even reductionist Daniel Dennett, who is a libertarian, has his version of decision-making:

The model of decision making I am proposing has the following feature: when we are faced with an important decision, a consideration-generator whose output is to some degree undetermined produces a series of considerations, some of which may of course be immediately rejected as irrelevant by the agent (consciously or unconsciously). Those considerations that are selected by the agent as having a more than negligible bearing on the decision then figure in a reasoning process, and if the agent is in the main reasonable, those considerations ultimately serve as predictors and explicators of the agent's final decision.

The Two-Stage Model of Arthur Compton championed the idea of human freedom based on quantum uncertainty and invented the notion of amplification of microscopic quantum events to bring chance into the macroscopic world. Years later, he clarified the two-stage nature of his idea in an Atlantic Monthly article in 1955:

A set of known physical conditions is not adequate to specify precisely what a forthcoming event will be. These conditions, insofar as they can be known, define instead a range of possible events from among which some particular event will occur. When one exercises freedom, by his act of choice he is himself adding a factor not supplied by the physical conditions and is thus himself determining what will occur. That he does so is known only to the person himself. From the outside one can see in his act only the working of physical law. It is the inner knowledge that he is in fact doing what he intends to do that tells the actor himself he is free.

At first Karl Popper dismissed quantum mechanics as being no help with free will, but later describes a two-stage model paralleling Darwinian evolution, with genetic mutations being probabilistic and involving quantum uncertainty:

In 1977 he gave the first Darwin Lecture "Natural Selection and the Emergence of Mind". In it he said he had changed his mind (a rare admission by a philosopher) about two things. First he now thought that natural selection was not a "tautology" that made it an unfalsifiable theory. Second, he had come to accept the random variation and selection of ideas as a model of free will. The selection of a kind of behavior out of a randomly offered repertoire may be an act of choice, even an act of free will. I am an indeterminist; and in discussing indeterminism I have often regretfully pointed out that quantum indeterminacy does not seem to help us;¹ for the amplification of something like, say, radioactive disintegration processes would not lead to human action or even animal action, but only to random movements. This is now the leading two-stage model of free will. I have changed my mind on this issue. A choice process may be a selection process, and the selection may be from some repertoire of random events, without being random in its turn. This seems to me to offer a promising solution to one of our most vexing problems, and one by downward causation.

These accounts span diverse thinkers, from James, through Dennett to Compton, so whether you are a materialist or a mentalist you can adapt two process volition to your taste. Therefore it says nothing about the nature of conscious decision making or the hard problem of volition. The key is that (1) something generates a set of possibilities either randomly or otherwise and (2) the mind/brain chooses one to enact, computationally, rationally or intuitively. Computationalists can say (1) is random and (2) is computational. Quantum mechanics provides for both: (1) is the indeterminacy of collapse in von Neumann process 1 and (2) is the collapsed particle dynamics of the Schrödinger equation aka von Neumann process 2.

Symbiotic Existential Cosmology affirms two empirical modes – objective verified empirical observation and subjective affirmed empirical experience, both of which are amenable to the same statistical methods. This ties to the conclusion that subjective conscious volition has efficacy over the physical universe and to the refutation of pure physicalism because causal closure of the physical universe is unprovable but empirical experience of our subjectively conscious actions towards our own physical survival clearly affirm we have voluntary conscious volition having physical effect.

Benjamin Libet has become notorious for his readiness potential suggesting consciousness has no physical effect but his statement on free will precisely echoes Symbiotic Existential Cosmology with exactly the same ethical emphasis:

Given the speculative nature of both determinist and non-determinist theories, why not adopt the view that we do have free will (until some real contradictory evidence may appear, if it ever does). Such a view would at least allow us to proceed in a way that accepts and accommodates our own deep feeling that we do have free will. We would not need to view ourselves as machines that act in a manner completely controlled by the known physical laws.

In Symbiotic Existential Cosmology the transactional interpretation is envisaged as allowing a form of prescience because the collapse has implicit information about the future state of the universe in which the absorbers exist. This may appear logically paradoxical but no classical information is transferred so there is no inconsistency. Modelling the collapse appears to happen outside space-time, but actually it is instantaneous, so dual-time is just a core part of the heuristic to understand the non-linear process.

It is absolutely necessary for subjective conscious physical volition to be efficacious over mere computation, or it fails to confer an evolutionary advantage and would be eliminated over time by neutral and deleterious mutations in favour of purely computational brains. The fact that this hasn't happened in the 2 bYa since the eucaryote emergence tells us it DOES have an advantage in terms of intuitive anticipation shared, by all animals, who unlike us, lack rational thought, and single celled eucaryotes who have nothing more than social neurotransmitters and excitable membranes to do the same uncanny trick. So we have to look to physics and the nature of uncertainty to solve this, because environmental uncertainty has its root in quantum uncertainty, just as throwing a die does by setting off a butterfly-effect process.

This evolutionary advantage depends on a transformation of Doyle's (1), in transactional collapse being a form of non-random hidden-variable theory in which non-local correlations of the universal wave function manifest as a complex system during collapse in a way that looks deceptively like randomness because it is a complex chaotic ergodic process. It then completely transforms part (1) of the two process model of volition because the intuitive choices are anticipatory, like integral transforms of the future which we can't put into a logical causality without paradox, but which can coexist before collapse occurs. Transactional collapse incorporates implicit future information about the actual potential absorbers.

"God does not play dice with the universe." A Einstein

There is thus a clear biological requirement for subjective conscious physical volition and that is to ensure survival of existential threats in the wild. We can imagine a computer attempting to do the two-process, by throwing up heuristic options on a weighted probabilistic basis process (1) and then optimising in a choice process (2). We can imagine this is also in a sense what we do when we approach a problem rationally. But that's not what survival in the wild is about. It's about computationally intractable environmental many body problems that also involve other conscious agents, snakes, tigers and other humans, so are formally and computationally undecidable. Hence the role of intuition.

The transactional interpretation as in fig 73, becomes the key to avoiding the mechanistic pseudo-deterministic random (1) plus computational (2) process of the two process decision-making and that is why we are able to exist and evolve as conscious anticipating sentient beings. You can imagine that an advanced AI package like chatGPT can get to the water hole but there is no evidence this is possible if it is covered in smelly food attractants, with unpredictable predators on the prowl. There is not even any good evidence that rational cognition can save our bacon. It all comes down to salience, sensory acuity, paranoia and intuition.

One may think one can depend on randomness alone to provide hypothetical heuristics and avoid getting "stuck in a rut", as a Hopfield network does by thermodynamic annealing and is also key to why the brain uses edge-of-chaos instability, but randomness is arbitrary and artificial. A computer uses the time and date to seed a non-random highly ergodic process to simulate randomness. All molecular billiards arises from a wave-particle process of spreading wave functions involving quantum uncertainty just as photons do. The same for decoherence models of collapse.

This is the ultimate flaw in relying on the two process approach of Doyle based on randomness but it comes at the cost of a speculative leap about what is happening in von Neumann process 1. Quantum transactional collapse can occur instantaneously across space-time in a manner which may well be rationally contradictory about what time is, but is perfectly consistent with conscious intuition. If the universe is in a dynamical state between a multiverse and collapse to classicality, and conscious organisms, among other entities participate in collapse, we have a link between surviving

environmental uncertainty and quantum indeterminacy. If this is just randomness no anticipatory advantage results, but if it is part of a delocalised complex system hidden variable theory it can.

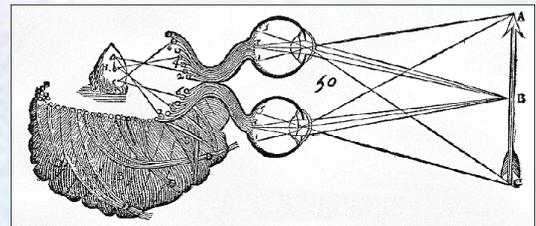

Any attempt to think about it in a causal sequence or even reason it rationally to unravel intuition would lead to paradox, so rational thought can't capture it, but intuition does reveal it, but not in a way we can prove with high sigma causality statistics because to do that we have to invoke an IID process (independent identically-distributed set of measurements), which sends the whole process down the drain of the Born probability interpretation to randomness, when the biological reality in ever-changing brain states is that each step changes the measurement context, as a non IID process, so it amounts to Schrödinger turtles all the way down.

I am prepared to make this quantum leap into special relativistic retro-causal transactions because it is consistent with quantum mechanics. It urgently needs to be explored because it has the key to how and why we are here as conscious sentient beings in this universe, in which life rises to climax conscious complexity.

Descartes originally claimed that consciousness requires an immaterial soul, which interacts with the body via the pineal gland of the brain. Gert-Jan Lokhorst (2021) describes the details of how Descartes conceived the action of the pineal on a mechanical body, noting its antiquated basis, in a purely mechanical machine made of earth:

*The pineal gland played an important role in Descartes' account because it was involved in sensation, imagination, memory and the causation of bodily movements. Unfortunately, however, some of Descartes' basic anatomical and physiological assumptions were totally mistaken, not only by our standards, but also in light of what was already known in his time. ... The bodies of Descartes' hypothetical men are nothing but machines: "I suppose the body to be **nothing but a statue or machine made of earth**, which God forms with the explicit intention of making it as much as possible like us". The working of these bodies can be **explained in purely mechanical terms**.*

Fig 84: Diagram from Descartes' *Treatise of Man* (1664), showing the formation of inverted retinal images in the eyes, and the transmission of these images, via the nerves so as to form a single, re-inverted image (an *idea*) on the surface of the pineal gland.

As a young man, Descartes had had a mystical experience in a sauna on the Danube: three dreams, which he interpreted as a message telling him to come up with a theory of everything and on the strength of this, dedicated his life to philosophy, leading to his iconic quote – *Cogito ergo sum* “I think therefore I am” – leading to Cartesian dualism, immortalised in the homunculus. This means that, in a sense, the Cartesian heritage of dualism is a genuine visionary attempt on Descartes' part, to come to terms with his own conscious experience in terms of his cognition, in distinction from the world around him. Once the separation invoked by the term dualism is replaced by complementarity, we arrive at Darwinian panpsychism.

*Experior, ergo sum, experimur, ergo sumus.
I experience therefore I am, we experience therefore we are!*

Key to Descartes' interpretation, the active process that corresponds to neuronal action potential are “animal spirits” running in the nerves from sense organ to the pineal and back out to the muscles:

In Descartes' description of the role of the pineal gland, the pattern in which the animal spirits flow from the pineal gland was the crucial notion. He explained perception as follows. The nerves are hollow tubes filled with animal spirits. They also contain certain small fibers or threads which stretch from one end to the other. These fibers connect the sense organs with certain small valves in the walls of the ventricles of the brain. When the sensory organs are stimulated, parts of them are set in motion. These parts then begin to pull on the small fibers in the nerves, with the result that the valves with which these fibers are connected are pulled open, some of the animal spirits in the pressurized ventricles of the brain escape, and (because nature abhors a vacuum) a low-pressure image of the sensory stimulus appears on the surface of the pineal gland. It is this image which then “causes sensory perception” of whiteness, tickling, pain, and so on. “It is not [the figures] imprinted on the external sense organs, or on the internal surface of the brain, which should be taken to be ideas—but only those which are traced in the spirits on the surface of the gland H (where the seat of the imagination and the ‘common’ sense is located).

This account is an attempt to explain in one model both subjective consciousness and volition over the world:

Finally, Descartes presented an account of the origin of bodily movements. He thought that there are two types of bodily movement. First, there are movements which are caused by movements of the pineal gland. The pineal gland may be moved in three ways: (1)

by “the force of the soul,” provided that there is a soul in the machine; (2) by the spirits randomly swirling about in the ventricles; and (3) as a result of stimulation of the sense organs. The role of the pineal gland is similar in all three cases: as a result of its movement, it may come close to some of the valves in the walls of the ventricles. The spirits which continuously flow from it may then push these valves open, with the result that some of the animal spirits in the pressurized ventricles can escape through these valves, flow to the muscles by means of the hollow, spirit-filled nerves, open or close certain valves in the muscles which control the tension in those muscles, and thus bring about contraction or relaxation of the muscles.

It also embraces higher functioning including imagination:

Imagination arises in the same way as perception, except that it is not caused by external objects. Continuing the just-quoted passage, Descartes wrote: “And note that I say ‘imagines or perceives by the senses’. For I wish to apply the term ‘idea’ generally to all the impressions which the spirits can receive as they leave gland H. These are to be attributed to the ‘common’ sense when they depend on the presence of objects; but they may also proceed from many other causes (as I shall explain later), and they should then be attributed to the imagination”.

Westphal (2016) notes: *According to Descartes, matter is essentially spatial, and it has the characteristic properties of linear dimensionality. Things in space have a position, at least, and a height, a depth, and a length, or one or more of these. Mental entities, on the other hand, do not have these characteristics. We cannot say that a mind is a two-by-two-by-two-inch cube or a sphere with a two-inch radius, for example, located in a position in space inside the skull. This is not because it has some other shape in space, but because it is not characterized by space at all.*

The whole problem contained in such questions arises simply from a supposition that is false and cannot in any way be proved, namely that, if the soul and the body are two substances whose nature is different, this prevents them from being able to act on each other – René Descartes

Descartes is surely right about this. The “nature” of a baked Alaska pudding, for instance, is very different from that of a human being, since one is a pudding and the other is a human being — but the two can “act on each other” without difficulty, for example when the human being consumes the baked Alaska pudding and the baked Alaska in return gives the human being a stomachache.

In a letter dated May 1643, Princess Elisabeth wrote to Descartes: *I beg you to tell me how the human soul can determine the movement of the animal spirits in the body so as to perform voluntary acts — being as it is merely a conscious substance. For the determination of the movement seems always to come about from the moving body’s being propelled — to depend on the kind of impulse*

Without minds to direct their boldly movements ... animals must be regarded as unthinking, unfeeling machines that move like clockwork – René Descartes

I beg you to tell me how the human soul can determine the movement of the animal spirits in the body so as to perform voluntary acts — being as it is merely a conscious substance – Princess Elisabeth

it gets from what it sets in motion, or again, on the nature and shape of this latter thing’s surface. Now the first two conditions involve contact, and the third involves that the impelling [thing] has extension; but you utterly exclude extension from your notion of soul, and contact seems to me incompatible with a thing’s being immaterial.

When Elisabeth and Descartes mention “animal spirits” (from the Greek physician and philosopher Galen) they are writing about something that plays roughly the role of signals in the nerve fibres of modern physiology. For Descartes, the animal spirits were not ghostly apparitions, but part of a theory that claimed that muscles were moved by inflation with air, the so-called balloonist theory. The animal spirits were fine streams of air that inflated the muscles and “animal” does not mean the beasts, but derives from “anima,” the soul.

Secondly, when Elisabeth writes that “you utterly exclude extension from your notion of soul,” she is referring to the fact that Descartes defines mind and matter in such a way that the two are mutually exclusive. Mind is consciousness, which has no extension or spatial dimension, and matter is not conscious, since it is completely defined by its spatial dimensions and location. Since mind lacks a location and spatial dimensions, Elisabeth is arguing, it cannot make contact with matter, which requires physical impinging upon an object and ensuing motion.

Westphal (2016) notes: *We have inherited the sharp distinction between mind and body, though not exactly in Descartes’s form, but we have not inherited Descartes’s solution to the mind-body problem. So we are left with the problem, minus a solution. We see that the experiences we have, such as experiences of color, are indeed very different from the electromagnetic radiation that ultimately produces them, or from the activity of the neurons in the brain. We are bound to wonder how the uncolored radiation can*

produce the color, even if its effects can be followed as far as the neurons in the visual cortex. In other words, we make a sharp distinction between physics and physiology on the one hand, and psychology on the other, without a principled way to connect them.

Skirry (2023) notes: *Human beings are supposed to be combinations of mind and body such that the mind's choices can cause modes of motion in the body, and motions in certain bodily organs, such as the eye, cause modes of sensation in the mind. ... Take for example a voluntary choice, or willing, to raise one's hand in class to ask a question. The arm moving upward is the effect while the choice to raise it is the cause. But willing is a mode of the non-extended mind alone, whereas the arm's motion is a mode of the extended body alone: how can the non-extended mind bring about this extended effect? It is this problem of voluntary bodily motion or the so-called problem of "mind to body causation" that so troubled Gassendi and Elizabeth. The crux of their concern was that in order for one thing to cause motion in another, they must come into contact with one another as, for example, in the game of pool the cue ball must be in motion and come into contact with the eight-ball in order for the latter to be set in motion. The problem is that, in the case of voluntarily bodily movements, contact between mind and body would be impossible given the mind's non-extended nature. This is because contact must be between two surfaces, but surface is a mode of body, as stated at Principles of Philosophy part II, section 15. Accordingly, the mind does not have a surface that can come into contact with the body and cause it to move. So, it seems that if mind and body are completely different, there is no intelligible explanation of voluntary bodily movement.*

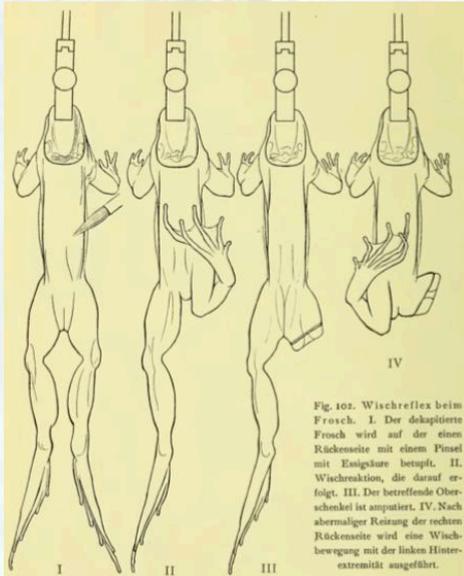

Lokhorst notes that only a few people accepted Descartes' pineal neurophysiology when he was still alive, and it was almost universally rejected after his death, partly because the pineal is no different in all mammals so cannot reflect the human soul. In philosophy, Cartesian interactionism immediately provoked "either ridicule or disgust" (Spinoza 1677), usually because it was seen as raising more problems than it solved, and it continues to do so to this day.

I do not forget, that the illustrious Descartes, though he believed, that the mind has absolute power over its actions, strove to explain human emotions by their primary causes, and, at the same time, to point out a way, by which the mind might attain to absolute dominion over them. However, in my opinion, he accomplishes nothing beyond a display of the acuteness of his own great intellect. ... For he maintained, that the soul or mind is specially united to a particular part of the brain, namely, to that part called the pineal gland, by the aid of which the mind is enabled to feel all the movements which are set going in the body, and also external objects, and which the mind by a simple act of volition can put in motion in various ways. He asserted, that this gland is so suspended in the midst of the brain, that it could be moved by the slightest motion of the animal spirits: further, that this gland is suspended in the midst of the brain in as many different manners, as the animal spirits can impinge thereon; and, again, that as many different marks are impressed on the said gland, as there are different external objects which impel the animal spirits towards it; whence it follows, that if the will of the soul suspends the gland in a position, wherein it has already been suspended once before by the animal spirits driven in one way or another, the gland in its turn reacts on the said spirits, driving and determining them to the condition wherein they were, when repulsed before by a similar position of the gland. He further asserted, that every act of mental volition is united in nature to a certain given motion of the gland. For instance, whenever anyone desires to look at a remote object, the act of volition causes the pupil of the eye to dilate, whereas, if the person in question had only thought of the dilatation of the pupil, the mere wish to dilate it would not have brought about the result, inasmuch as the motion of the gland, which serves to impel the animal spirits towards the optic nerve in a way which would dilate or contract the pupil, is not associated in nature with the wish to dilate or contract the pupil, but with the wish to look at remote or very near objects. Lastly, he maintained that, although every motion of the aforesaid gland seems to have been united by nature to one particular thought out of the whole number of our thoughts from the very beginning of our life, yet it can nevertheless become through habituation associated with other thoughts. ... He thence concludes, that there is no soul so weak, that it cannot, under proper direction, acquire absolute power over its passions. For passions as defined by him are "perceptions, or feelings, or disturbances of the soul, which are referred to the soul as species, and which (mark the expression) are produced, preserved, and strengthened through some movement of the spirits" (Spinoza 1677).

This reveals an important principle at the core of unravelling the mind-brain or consciousness-universe relationship. Elizabeth's critique is incorrect because she was assuming any interaction with a physical process has to be classically causal, but Descartes' reliance on a physical entity, the pineal made the same error, assuming the interaction portal between a subjective and objective is a classical physical entity, the pineal, rather than an unstable process. A key postulate of Symbiotic Existential Cosmology is that subjective and objective aspects of cosmological reality are linked through quantum uncertainty, as are several theories of consciousness that cite quantum physics. Symbiotic Existential Cosmology is also an interactionist cosmology that posits an active relationship between subjective consciousness and the physical universe through the efficacy of subjective conscious volition, but it does so without citing an exceptional quantum process that can become refuted later, as Hameroff-Penrose does, by combining specific unestablished microtubular quantum computations, and gravitational collapse theories of quantum uncertainty, but rather asserts that the normal biological processes of brain dynamics achieve these capacities as they stand, thus retaining concordance between empirical neuroscience and physics unscathed by contingent exceptional assumptions. By remaining agnostic about quantum interpretations it remains concordant with empirical neuroscience and physics.

The traditional view of subjective consciousness stemming from Thomas Huxley is that of epiphenomenalism – the view that mental events are caused by physical events in the brain, but have no effects upon any physical events.

The way paradigm shifts can occur can be no more starkly illustrated than in the way in which epiphenomenalism, behaviourism and pure materialism, including reductionism came to dominate the scientific view of reality and the conscious mind.

Huxley (1874) held the view, comparing mental events to a steam whistle that contributes nothing to the work of a locomotive. William James (1879), rejected this view, characterising epiphenomenalists' mental events as not affecting the brain activity that produces them "any more than a shadow reacts upon the steps of the traveller whom it accompanies" – thus turning subjective consciousness from active agency to being a mere passenger. Huxley's essay likewise compares consciousness to the sound of the bell of a clock that has no role in keeping the time, and treats volition simply as a symbol in consciousness of the brain-state cause of an action. Non-efficacious mental events are referred to in this essay as "collateral products" of their physical causes.

Fig 85: A decapitated frog uses its right foot to try to remove burning acid but when it is cut off it uses its left, although having no brain.

Klein (2021) in continuing paragraphs notes that the story begins with Eduard Pflüger's 1853 experiments showing that some decapitated vertebrates exhibit behaviour it is tempting to call purposive. The results were controversial because purposive behaviour had long been regarded as a mark of consciousness. Those who continued to think it was such a mark had to count a pithed frog – and presumably, a chicken running around with its head cut off – as conscious. You can see such ideas echoing today in [Solms and Friston's](#) (2018) brain-stem based model of consciousness.

But this view opened the way for epiphenomenalism: just as pithed frogs seem to act with purpose even though their behaviour is not really guided by phenomenal consciousness, so intact human behaviours may seem purposive without really being guided by phenomenal consciousness.

Descartes had famously contended that living animals might be like machines in the sense of being non-conscious organisms all of whose behaviours are produced strictly mechanistically. Those in the seventeenth and eighteenth century who adopted a broadly Cartesian approach to animal physiology are often called 'mechanists', and their approach is typically contrasted with so-called 'animists'. What separated the two groups was the issue of whether and to what extent the mechanical principles of Newton and Boyle could account for the functioning of living organisms. Even for those more inclined towards mechanism, though, animistic tendencies still underlay much physiological thinking throughout the early modern period. For instance, Giovanni Borelli (1608–1679) had developed a mechanistic account of how the heart pumps blood. But even Borelli gave the soul a small but important role in this motion. Borelli contended that 'the unpleasant accumulation of blood in the heart of the preformed embryo would be perceived by the "sentient faculty" (*facultas sensitiva*) of the soul through the nerves, which would then prompt the ventricle to contract'. Only after the process was thus initiated would the circulation continue mechanistically, as a kind of physical, acquired habit. But the ultimate cause of this motion was the soul.

Fig 86: Representation of consciousness from the seventeenth century by Robert Fludd, an English Paracelsian physician.

Now, suppose one accepts purposive behaviour as a mark of consciousness (or sensation, or volition, or all of these). Then one arrives at a surprising result indeed – that the brainless frog, properly prepared, remains a conscious agent. Of course, there is a lot riding on just what is meant by 'consciousness', 'sensation', and 'volition'. Pflüger himself often wrote about the decapitated frog's supposed 'consciousness' (Bewusstsein), but was rather loose and poetic in spelling out what that term was to mean. Still, his general thesis was clear enough: that in addition to the brain, the spinal cord is also an organ that independently produces consciousness. One controversial implication is that consciousness itself may be divisible (and so

literally extended; see Huxley, 1870 5–6) – it may exist in various parts of the nervous system, even in a part of the spinal cord that has been divided from the brain (Fearing 1930 162–3).

Lotze's thought was that these behaviours seem purposive only because they are complex. If we allow that the nervous system can acquire complex, reflexive actions through bodily learning, then we can maintain that these behaviours are mechanically determined, and not guided or accompanied by any phenomenal consciousness.

The difficulty with this response is that pithed frogs find ways to solve physical challenges they cannot be supposed to have faced before being pithed. For instance, suppose one places a pithed frog on its back, holds one leg straight up, perpendicular to the body, and irritates the leg with acid. The pithed frog will then raise the other leg to the same, odd position so as to be able to wipe away the irritant. Huxley also reports that a frog that is pithed above the medulla oblongata (but below the cerebellum) loses the ability to jump, even though the frog with the brain stem and cerebellum both intact is able to perform this action, at least in response to irritation. A frog pithed just below the cerebrum 'can see, swallow, jump, and swim', though still will typically move only if prompted by an outer stimulus (Huxley 1870 3–4).

Now what does Lewes mean by 'sensation' and 'volition'?

Do what we will, we cannot altogether divest Sensibility of its psychological connotations, cannot help interpreting it in terms of Consciousness; so that even when treating of sensitive phenomena observed in molluscs and insects, we always imagine these more or less suffused with Feeling, as this is known in our own conscious states. (Lewes 1877 188–9)

He saw that one must first settle an important issue before it is possible to interpret these experiments. He wrote, "we have no proof, rigorously speaking, that any animal feels; none that any human being feels; we conclude that men feel, from certain external manifestations, which resemble our own, under feeling; and we conclude that animals feel – on similar grounds."

Now, inasmuch as the actions of animals furnish us with our sole evidence for the belief in their feeling, and this evidence is universally considered as scientifically valid, it is clear that similar actions in decapitated animals will be equally valid; and when I speak of proof, it is in this sense. Spontaneity and choice are two signs which we all accept as conclusive of sensation and volition. (Lewes 1859 237–8).

Does Pflüger's experiment prove that there is sensation or volition in the pithed frog? We cannot tell, Lewes suggests, until we first settle on some third-person-accessible mark of sensation and volition. And the marks Lewes proposes are spontaneity and choice. For Lewes, every physiological change is in some sense sensory, and every physiological change thereby influences the 'stream of Consciousness', however slightly.

Thomas Huxley (1874) offered the most influential and provocative version of the conscious automaton theory in an address in Belfast. According to this view, 'consciousness', synonymous with Lewes' 'sensation' accompanies the body without acting on it, just as 'the steam-whistle which accompanies the work of a locomotive engine is without influence upon its machinery'. Conscious states are continually being caused by brain states from moment to moment, on this view, but are themselves causally inert. In other words, although Huxley accepted the existence of sensation, he rejected the existence of 'volition' (as Lewes had used that word). This is an early form of epiphenomenalism.

Pflüger and Lewes had indeed established the existence of purposive behaviour in pithed frogs, Huxley readily conceded (Huxley 1874 223). But since it is absurd (according to Huxley) to think the behaviour of brainless frogs is under conscious control, the correct lesson to draw from Pflüger and Lewes' results was that purposive actions are not sufficient to establish volition. In fact, Huxley evidently was unwilling to accept the existence of any behavioural mark of either sensation or volition.

It must indeed be admitted, that, if any one thinks fit to maintain that the spinal cord below the injury is conscious, but that it is cut off from any means of making its consciousness known to the other consciousness in the brain, there is no means of driving him from his position by logic. But assuredly there is no way of proving it, and in the matter of consciousness, if in anything, we may hold by the rule, 'De non apparentibus et de non existentibus eadem est ratio' ['what does not appear and what does not exist have the same evidence'] (Huxley, 1874, 220).

The mechanist's dilemma is the following 'paradox':

A: If one accepts any behavioural mark of sensation and volition, then the experimental data will force us to attribute sensation and volition to both decapitated and intact vertebrates alike.

B: If one rejects the existence of a behavioural mark, then one has no grounds for ascribing sensation or volition to either decapitated or intact vertebrates.

Huxley's pronouncement piggybacks on the position he took in the mechanist's dilemma. His claim that spinal consciousness cannot be observed amounts to the claim that such a consciousness cannot be observed first-personally. But that is the crux of the mechanist's dilemma.

Huxley nevertheless was reverential of the contribution made by Rene Descartes in understanding the physiology of the brain and body:

The first proposition culled from the works of Descartes which I have to lay before you, is one which will sound very familiar. It is the view, which he was the first, so far as I know, to state, not only definitely, but upon sufficient grounds, that the brain is the organ of sensation, of thought, and of emotion—using the word "organ" in this sense, that certain changes which take place in the matter of the brain are the essential antecedents of those states of consciousness which we term sensation, thought and emotion. ... It remained down to the time of Bichat [150 years later] a question of whether the passions were or were not located in the abdominal viscera. In the second place, Descartes lays down the proposition that all movements of animal bodies are affected by a change in form. of a certain part of the matter of their bodies, to which he applies the general term of muscle.

The process of reasoning by which Descartes arrived at this startling conclusion is well shown in the following passage of the "Réponses:"— "But as regards the souls of beasts, although this is not the place for considering them, and though, without a general exposition of physics, I can say no more on this subject than I have already said in the fifth part of my Treatise on Method; yet, I will further state, here, that it appears to me to be a very remarkable circumstance that no movement can take place, either in the bodies of beasts, or even in our own, if these bodies have not in themselves all the organs and instruments by means of which the very same movements would be accomplished in a machine. So that, even in us, the spirit, or the soul, does not directly move the limbs, but only determines the course of that very subtle liquid which is called the animal spirits, which, running continually from the heart by the brain into the muscles, is the cause of all the movements of our limbs, and often may cause many different motions, one as easily as the other.

Descartes' line of argument is perfectly clear. He starts from reflex action in man, from the unquestionable fact that, in ourselves, co-ordinate, purposive, actions may take place, without the intervention of consciousness or volition, or even contrary to the latter. As actions of a certain degree of complexity are brought about by mere mechanism, why may not actions of still greater complexity be the result of a more refined mechanism? What proof is there that brutes are other than a superior race of marionettes, which eat without pleasure, cry without pain, desire nothing, know nothing, and only simulate intelligence as a bee simulates a mathematician? ... Suppose that only the anterior division of the brain—so much of it as lies in front of the "optic lobes"—is removed. If that operation is performed quickly and skilfully, the frog may be kept in a state of full bodily vigour for months, or it may be for years; but it will sit unmoved. It sees nothing: it hears nothing. It will starve sooner than feed itself, although food put into its mouth is swallowed. On irritation, it jumps or walks; if thrown into the water it swims.

Klein (2018) notes that the crux of the paradigm shift was the competing research by the opposing groups and the way in which their research successes at the time led to success:

*But by the time of the Lewes contribution from 1877, the question was no longer whether this one subset of muscular action could be accounted for purely mechanistically. Now, the question had become whether the mechanistic approach to reflex action might be expanded to cover all muscular action. Lewes wrote that the 'Reflex Theory' had become a strategy where one attempted to specify 'the elementary parts involved' in every physiological function without ever appealing to 'Sensation and Volition' (Lewes, *Problems of Life and Mind*, 354).*

'That the majority of physiological opinion by the close of the century was in favor of the position of Pflüger's opponents seems certain', Fearing writes. 'Mechanistic physiology and psychology was firmly seated in the saddle' (Fearing, 1930, 185).

The concept of a mechanistic reflex arc came to dominate not just physiology, but psychology too. The behaviourist B. F. Skinner, for example, wrote his 1930 doctoral dissertation on how to expand the account of reflex action to cover all behaviour, even the behaviour of healthy organisms. Through the innovations of people like Skinner and, before him, Pavlov, behaviourism would establish itself as the dominant research paradigm.

Cannon (1911, 38) gave no real argument for why students should not regard purposive movement as a mark of genuine volition (beyond a quick gesture at Lotze's long-discredited retort to Pflüger). Without citing any actual experiments, Cannon simply reported, as settled scientific fact, that purposiveness does not entail intended action:

Purposive movements are not necessarily intended movements. It is probable that reaction directed with apparent purposefulness is in reality an automatic repetition of movements developed for certain effects in the previous experience of the intact animal. (ibid)

Schwartz et al. (2005) highlight the key role William James played in establishing the status of volitional will:

William James (1890 138) argued against epiphenomenal consciousness, by claiming that 'The particulars of the distribution of consciousness, so far as we know them, points to its being efficacious.' James (136) stated that 'consciousness is at all times primarily a selecting agency.' It is present when choices must be made between different possible courses of action. 'It is to my mind quite inconceivable that consciousness should have nothing to do with a business to which it so faithfully attends'.

These liabilities of the notion of epiphenomenal mind and consciousness lead many thinkers to turn to the alternative possibility that a person's mind and stream of consciousness is the very same thing as some activity in their brain: mind and consciousness are 'emergent properties' of brains. A huge philosophical literature has developed arguing for and against this idea.

They cite Sperry (1992) who adopted an 'identity theory' approach which he claimed was monist, in invoking a top-down system-theoretic notion of the mind as an abstraction of certain higher-level brain processes:

The core ideas of the arguments in favour of an identity-emergent theory of mind and consciousness are illustrated by Roger Sperry's (1992) example of a 'wheel'. A wheel obviously does something: it is causally efficacious; it carries the cart. It is also an emergent property: there is no mention of 'wheelness' in the formulation of the laws of physics and 'wheelness' did not exist in the early universe; 'wheelness' emerges only under certain special conditions. And the macro-scopic wheel exercises 'top-down' control of its tiny parts. ... The reason that mind and consciousness are not analogous to 'wheelness', within the context of classic physics, is that the properties that characterize 'wheelness' are properties that are entailed, within the conceptual framework of classic physics, by properties specified in classic physics, whereas the properties that characterize conscious mental processes, namely the various ways these processes feel, are not entailed within the conceptual structure provided by classic physics, but by the properties specified by classic physics.

They quote James again in their theory of volition, based on the repeated application of attention to the issue at hand:

In the chapter on will, in the section entitled 'Volitional effort is effort of attention', James (1892 417) writes: "Thus we find that we reach the heart of our inquiry into volition when we ask by what process is it that the thought of any given action comes to prevail stably in the mind. ... The essential achievement of the will, in short, when it is most 'voluntary,' is to attend to a difficult object and hold it fast before the mind. Effort of attention is thus the essential phenomenon of will. ... Consent to the idea's undivided presence, this is effort's sole achievement. Everywhere, then, the function of effort is the same: to keep affirming and adopting the thought which, if left to itself, would slip away".

Enshrining the concept of pure behaviourism (Stout 2003, Tanney 2022), and reductionism more generally Gilbert S(1949) claimed in "The Concept of Mind" that "mind" is "a philosophical illusion hailing from René Descartes, and sustained by logical errors and 'category mistakes' which have become habitual". Ryle rejected Descartes' theory of the relation between mind and body, on the grounds that it approaches the investigation of mental processes as if they could be isolated from physical processes. According to Ryle, the classical theory of mind, or "Cartesian rationalism," makes a basic category mistake (a new logical fallacy Ryle himself invented), as it attempts to analyse the relation between "mind" and "body" as if they were terms of the same logical category. The rationalist theory that there is a transformation into physical acts of some purely mental faculty of "Will" or "Volition" is therefore a misconception because it mistakenly assumes that a mental act could be and is distinct from a physical act, or even that a mental world could be and is distinct from the physical world. This theory of the separability of mind and body is described by Ryle as "the dogma of the ghost in the machine." However Ryle was not regarded as a philosophical behaviourist and writes that the "general trend of this book will undoubtedly, and harmlessly, be stigmatised as 'behaviourist'."

Symbiotic Existential Cosmology, classes itself as ICAM interactively complementary aspect monism, rather than dualism. The Stanford Encyclopaedia of Philosophy definitions for dualism (Robinson 2023) are:

Genuine **property dualism** occurs when, even at the individual level, the ontology of physics is not sufficient to constitute what is there. The irreducible language is not just another way of describing what there is, it requires that there be something more there than was allowed for in the initial ontology. Until the early part of the twentieth century, it was common to think that biological phenomena ('life') required property dualism (an irreducible 'vital force'), but nowadays the special physical sciences other than psychology are generally thought to involve only **predicate dualism** (that psychological or mentalistic predicates are (a) essential for a full description of the world and (b) are not reducible to physicalistic predicates). In the case of mind, property dualism is defended by those who argue that the qualitative nature of consciousness is not merely another way of categorizing states of the brain or of behaviour, but a genuinely emergent phenomenon.

Substance dualism: There are two important concepts deployed in this notion. One is that of substance, the other is the dualism of these substances. A substance is characterized by its properties, but, according to those who believe in substances, it is more than the collection of the properties it possesses, it is the thing which possesses them. So the mind is not just a collection of thoughts, but is that which thinks, an immaterial substance over and above its immaterial states.

In [Stanford](#), Tanney (2022) notes that Ryle's category error critique was centrally about the assumed distinctness of mind and body as "substances" in the context of absurdity of certain verbal sentence constructions:

When a sentence is (not true or false but) nonsensical or absurd, though its vocabulary is conventional and its grammatical construction is regular, we say that it is absurd because at least one ingredient expression in it is not of the right type to be coupled or to be coupled in that way with the other ingredient expression or expressions in it. Such sentences, we may say, commit type-trespasses or break type-rules. (1938, 178)

The category mistake Ryle identifies in "There is a mind and a body" or "there is a mind or a body" is less obvious. For it takes a fair bit of untangling to show that "mind" and "body" are different logical or grammatical types; a fact which renders the assertion of either the conjunction or the disjunction nonsensical.

Robinson (2023) further notes both the veridical affirmation of interactivity in everyday life and the unverifiability of physical causal closure:

Interactionism is the view that mind and body – or mental events and physical events – causally influence each other. That this is so is one of our common-sense beliefs, because it appears to be a feature of everyday experience. The physical world influences my experience through my senses, and I often react behaviourally to those experiences. My thinking, too, influences my speech and my actions. There is, therefore, a massive natural prejudice in favour of interactionism.

Causal Closure Most discussion of interactionism takes place in the context of the assumption that it is incompatible with the world's being 'closed under physics'. This is a very natural assumption, but it is not justified if causal overdetermination of behaviour is possible. There could then be a complete physical cause of behaviour, and a mental one. The problem with closure of physics may be radically altered if physical laws are indeterministic, as quantum theory seems to assert. If physical laws are deterministic, then any interference from outside would lead to a breach of those laws. But if they are indeterministic, might not interference produce a result that has a probability greater than zero, and so be consistent with the laws? This way, one might have interaction yet preserve a kind of nomological closure, in the sense that no laws are infringed. ... Some argue that indeterminacy manifests itself only on the subatomic level, being cancelled out by the time one reaches even very tiny macroscopic objects: and human behaviour is a macroscopic phenomenon. Others argue that the structure of the brain is so finely tuned that minute variations could have macroscopic effects, rather in the way that, according to 'chaos theory', the flapping of a butterfly's wings in China might affect the weather in New York. (For discussion of this, see Eccles (1980), (1987), and Popper and Eccles (1977)). Still others argue that quantum indeterminacy manifests itself directly at a high level, when acts of observation collapse the wave function, suggesting that the mind may play a direct role in affecting the state of the world (Hodgson 1988; Stapp 1993).

Symbiotic Existential Cosmology does not assert "substance" dualism, as subjective conscious volition is not treated as a "substance", in the way mind was in the manner of objective physical entities, in Ryle's complaint against Cartesian dualism. SEC invokes a unified Cosmos in which primal subjectivity and the objective universe are complementary mutually-interactive principles in a universe which is not causally closed and in which volitional will can act without causal conflict, through quantum uncertainty. Life is also subject to a degree of overdeterminism due to teleological influences such as [autopoiesis](#), e.g. in the negentropic nature of life and evolution as self-organising far-from-equilibrium thermodynamic systems, however this is insufficient to eliminate the need for conscious-physical interactivity to ensure survival. The subjective aspect is fully compliant with determined physical boundary conditions of brain states, except in so far as subjective volition interacts with environmental quantum-derived uncertainty through quantum-sensitive unstable brain dynamics, forming a contextual filter theory of brain function on conscious experience, rather than a causally-closed universe determining ongoing brain states. Thus, no pure-subjective interactivity is mandatory, as occurs in traditional forms of panpsychism, such as pan-*proto-* or *cosmo-*psychism.

The key counter to Ryle's complaint is that if I say in response to a received e-mail that the author has demonstrated through consciously intending to compose and send their response in physical form that "you have demonstrated that your subjective conscious volition has efficacy over the physical universe" this is not grammatically, semantically, or categorically absurd, but a direct empirical observation from experience that raises no physical or philosophical inconsistencies, but fully confirms empirical experience of subjective physical conscious agency, consistent with civil and criminal law of conscious intentional responsibility. Ryle's strategy is linguistic. He attacks both the ontological commitment (the view that mind and body are somehow fundamentally different or distinct, but nonetheless interact) and the epistemological commitment (the inability to confirm other people are conscious because subjectivity is private) of what he calls the "official doctrine" (Tanney 2022). The problem is that, by dealing with it in a purely linguistic analysis, we are dealing only with objective semantic and grammatical connotations so the argument is intrinsically objective. We know that subjectivity is private and objectivity is public. That's just the way it is! We also know that in all our discourses subjective-objective interactivity occurs. A hundred percent of our experience is subjective and the world around us is inferred from our subjectively conscious experiences of it.

The way out is not to deny mind, or consciousness itself which we are all trying to fathom, or we are back to the hard problem of the objectively unfathomable explanatory gap. The way out is that the above statement "you have demonstrated that your subjective conscious volition has efficacy over the physical universe" is something that also involves conscious physical volition we can mutually agree on because it's evidenced in our behaviour in consciously responding to one another. Ryle is sitting by himself in his office dreaming up linguistic contradictions, but these evaporate through mutual affirmation of subjective volition. That's the transactional principle manifest. Then the category error vanishes in the subjective empirical method. This is why extending the hard problem to volition has been essential, because it's the product of conscious volition in behaviour that is verifiable.

In Stanford (Tanney 2022) notes that Cartesianism is at worst "dead" in only one of its ontological aspects: Substance dualism may have been repudiated but property dualism still claims a number of contemporary defenders. Furthermore, although Descartes embraced a form of substance dualism, in the sense that the pineal acted in response to the soul by making small movements that initiated wider responses in the brain, the pineal is still a biological entity, so the category error is misconceived. His description is remarkably similar to instabilities in brain dynamics potentially inducing global changes in brain dynamics. Compounded with the inability of materialism to solve the hard problem, science is thus coming full circle. It is not just a question of sentence construction but Cosmology.

Ryle's rejection of Cartesian dualism led to a second paradigm shift in which molecular biology, succeeding Watson and Crick's discovery of the structure of DNA, led to ever more effective 'laying bare' of all biological processes including the brain, accompanied by new technologies of multi-electrode EEG and MEG and functional fMRI imaging using magnetic resonance imaging. So that subjective consciousness became effectively ignored in the cascade of purely functionalist results of how human brain dynamics occurs.

Anil Seth (2018) notes:

The relationship between subjective conscious experience and its biophysical basis has always been a defining question for the mind and brain sciences. But, at various times since the beginnings of neuroscience as a discipline, the explicit study of consciousness has been either treated as fringe or excluded altogether. Looking back over the past 50 years, these extremes of attitude are well represented. Roger Sperry (1969, 532), pioneer of split-brain operations and of what can now be called 'consciousness science' lamented in 1969 that 'most behavioral scientists today, and brain researchers in particular, have little use for consciousness'. Presciently, in the same article he highlighted the need for new technologies able to record the 'pattern dynamics of brain activity' in elucidating the neural basis of consciousness. Indeed, modern neuroimaging methods have had a transformative impact on consciousness science, as they have on cognitive neuroscience generally. ... Informally, consciousness science over the last 50 years can be divided into two epochs. From the mid-1960s until around 1990 the fringe view held sway, though with several notable exceptions. Then, from the late 1980s and early 1990s, first a trickle and more recently a deluge of research into the brain basis of consciousness, a transition catalysed by – among other things – the activities of certain high-profile scientists (e.g. the Nobel laureates Francis Crick and Gerald Edelman) and by the maturation of modern neuroimaging methods, as anticipated by Sperry.

Symbiotic cosmology, based on complementary, unlike a strictly dualist description, is coherent. This coherence – forming a complete whole without discrete distinction – is manifestly true in that we can engage either a subjective discourse on our experiences or an objective account of their material circumstances in every situation in waking life, just as the wave and particle aspects of quanta are coherent and cannot be separated, as complementary manifestations. We thus find that the human discourse on our existential condition has two complementary modes, the one fixed in the objective physical description of the world around us using logical and causal operations and the other describing our subjective conscious experiences, as intelligent sensual beings, which are throughout our lives, our sole source of personal knowledge of the physical world around us, without which we would have no access to the universe at large, let alone to our dreams, memories and reflections (Jung 1963), all of which are conscious in nature, and often ascribed to be veridical, rather than imaginary, in the case of dreams and visionary states.

In Erwin Schrödinger's words (1944): *"The world is a construction of our sensations, perceptions, memories. It is convenient to regard it as existing objectively on its own. But it certainly does not become manifest by its mere existence" ... "The reason why our sentient, perceiving and thinking ego is met nowhere within our scientific world picture can easily be indicated in seven words: Because it is itself that world picture".*

A central problem faced by detractors of the role of consciousness in both the contexts of the brain and the quantum universe is that many of the materialist arguments depend on an incorrectly classical view of causality, or causal closure, in the context of brain dynamics, which are fundamentally inconsistent with quantum reality. In the brain

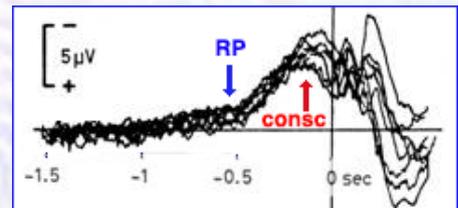

context, this is purported to eliminate an adaptive role for consciousness in human and animal survival, reducing it to a form of epiphenomenalism, in which volitional will would be a self-serving delusion. This follows lines of thinking derived from computational ideas that interfering with a computational process would hinder its efficiency.

In relation to volitional will, Chalmers & McQueen (2021) note: *“There are many aspects to the problem of consciousness, including the core problem of why physical processes should give rise to consciousness at all. One central aspect of the problem is the consciousness-causation problem: It seems obvious that consciousness plays a causal role, but it is surprisingly hard to make sense of what this role is and how it can be played.”*

The problem with the idea of objective brain processing being causally closed is fivefold. **Firstly** the key challenges to organismic survival are computationally intractable, open environment problems which may be better served by edge of chaos dynamics than classical computation. **Secondly**, many problems of survival are not causally closed at all because both evolution and organismic behaviour are creative processes, in which there are many viable outcomes, not just a single logically defined, or optimal one. **Thirdly**, quantum uncertainty and its deeper manifestations in entanglement, are universal, both in the brain and the environment, so there are copious ways for consciousness to intervene, without disrupting causally deterministic processes, and this appears to be its central cosmological role. **Fourthly**, the notion runs headlong into contradiction with our everyday experience of volition, in which we are consciously aware of our volitional intent and of its affects both in our purposive decision-making and acts affecting the world around us. For causal closure to be true, all our purposive decisions upon which we depend for our survival would be a perceptual delusion, contradicting the manifest nature of veridical perception generally. **Fifthly**, the work of Libet through to Schurger et al. below, demonstrates causal closure is unproven and is unlikely to remain so given the edge-of-chaos instability of critical brain processes in decision-making in the quantum universe.

The Hard Problem of Volition: The Readiness Potential and its Critics

Challenging the decision-making role of consciousness, Libet (1983, 1989) asked volunteers to flex a finger or wrist. When they did, the movements were preceded by a dip in the brain signals being recorded, called the "readiness potential". He interpreted this RP a few tenths of a second before the volunteers said they had decided to move, as the brain preparing for movement. Libet concluded that unconscious neural processes determine our actions before we are ever aware of making a decision. Since then, others have quoted the finding as evidence that free will is an illusion.

However Libet (1999) in "Do we have free-will?", himself makes the most convincing case possible for subjective consciousness having the capacity for free-will, signally invoking a two-process form of volition:

I have taken an experimental approach to this question. Freely voluntary acts are preceded by a specific electrical change in the brain (the 'readiness potential', RP) that begins 550 ms before the act. Human subjects became aware of intention to act 350–400 ms after RP starts, but 200 ms. before the motor act. The volitional process is therefore initiated unconsciously. But the conscious function could still control the outcome; it can veto the act. Free will is therefore not excluded. These findings put constraints on views of how free will may operate; it would not initiate a voluntary act but it could control performance of the act. The findings also affect views of guilt and responsibility.

But the deeper question still remains: Are freely voluntary acts subject to macro- deterministic laws or can they appear without such constraints, non-determined by natural laws and 'truly free'? I shall present an experimentalist view about these fundamental philosophical opposites. ... The question of free will goes to the root of our views about human nature and how we relate to the universe and to natural laws. Are we completely defined by the deterministic nature of physical laws? Theologically imposed fateful destiny ironically produces a similar end-effect. In either case, we would be essentially sophisticated automatons, with our conscious feelings and intentions tacked on as epiphenomena with no causal power. Or, do we have some independence in making choices and actions, not completely determined by the known physical laws? The initiation of the freely voluntary act appears to begin in the brain unconsciously, well before the person consciously knows he wants to act! Is there, then, any role for conscious will in the performance of a voluntary act? (see Libet, 1985). To answer this it must be recognized that conscious will (W) does appear about 150 msec. before the muscle is activated, even though it follows onset of the RP.

Potentially available to the conscious function is the possibility of stopping or vetoing the final progress of the volitional process, so that no actual muscle action ensues. Conscious-will could thus affect the outcome of the volitional process even though the latter was initiated by unconscious cerebral processes. Conscious-will might block or veto the process, so that no act occurs. The existence of a veto possibility is not in doubt. The subjects in our experiments at times reported that a conscious wish or urge to act appeared but that they sup- pressed or vetoed that. ... My conclusion about free will, one genuinely free in the non-determined sense, is then

that its existence is at least as good, if not a better, scientific option than is its denial by determinist theory. Given the speculative nature of both determinist and non-determinist theories, why not adopt the view that we do have free will (until some real contradictory evidence may appear, if it ever does). Such a view would at least allow us to proceed in a way that accepts and accommodates our own deep feeling that we do have free will. We would not need to view ourselves as machines that act in a manner completely controlled by the known physical laws.

Nevertheless, articulating a theory heavily dependent on the readiness potential, Budson et al. (2022) claim all the brain's decision-making procedures are unconscious, but followed half a second later by conscious experience that is just a memory-based constructive representation of future outcomes. According to the researchers, this theory is important because it explains that all our decisions and actions are actually made unconsciously, although we fool ourselves into believing that we consciously made them:

In a nutshell, our theory is that consciousness developed as a memory system that is used by our unconscious brain to help us flexibly and creatively imagine the future and plan accordingly. What is completely new about this theory is that it suggests we don't perceive the world, make decisions, or perform actions directly. Instead, we do all these things unconsciously and then—about half a second later—consciously remember doing them. We knew that conscious processes were simply too slow to be actively involved in music, sports, and other activities where split-second reflexes are required. But if consciousness is not involved in such processes, then a better explanation of what consciousness does was needed.

But this notion is itself a delusion. The conscious brain has evolved to be able to co-opt very fast subconscious processes to orchestrate in real time, highly accurate, innovative conscious responses, which the agent is fully aware of exercising in real time. The evidence is that conscious control of subconscious fast processing, e.g. via insular von-Economo neurons, and basal ganglia, occurs in parallel in real time. Tennis could not be played if the players' conscious reactions were half a second behind the ball. They could not represent, or accurately respond to the actual dynamics.

Likewise Earl (2014) cite the notion that consciousness is solely information in various forms that is associated with a flexible response mechanism (FRM) for decision-making, planning, and generally responding in nonautomatic ways. Both these are tautologous because information is both subjective and objective and non-conscious responses ARE physically automatic. Earl attempts to discount the validity of our subjective experience of volition by claiming it is a false assumption and fails to include all the mechanical details of how an act is generated:

When I decide to pick up a cup and do so, I may believe that my thought initiates my action, but what I observe is I have the thought of picking up the cup and then reach out and take the cup. I do not experience the information manipulations that must occur to initiate my action, and I have no evidence that my action is consciously initiated. One tends to assume one's intentional actions are consciously initiated, but as Wegner and Wheatley (1999) reported, we may perceive our actions as consciously caused if the thought occurs before the act and is consistent with the act, and there are no other likely causes.

While this is not going so far as to claim the conscious experience of volition is a delusion that evolved to give the epiphenomenal organism confidence in its ability to act, it is incorrectly claiming our experience of willed intentional decision making behaviour, key to our survival, is a false assumption, associating unconnected causes and effects:

In any intentional action, one never experiences the complete sequence of events from the starting conditions to completing the action. Bowers (1984, p. 249) wrote that "one can introspectively notice and/or recall antecedents of one's behavior but the causal connection linking the determining antecedents and the behavior to be explained is simply not directly accessible to introspection. Rather, the causal link between antecedents and their consequences is provided by an inference, however implicit and invisible." There are gaps in every experience of intentional choice, intentional initiation of responses, intentional control of attention or behavior, and in thinking, speaking, problem solving, creativity, and every other action with which consciousness is associated; and in each of these activities the executive mental process is missing from consciousness.

These arguments do not constitute a valid critique, given the ability of non-conscious processes to complement and prepare the experiential context for a comprehensive conscious decision. To have to experience every mechanical aspect of an intentional action would subject the flow of subjective consciousness to strategic overload and obliterate the efficiency of the FRM model. Conscious experience gives us the effective overview to act decisively in real time.

Libet's claim has been undermined by more recent studies. Bredikhin et al.(2023) have discovered confounding faults in Libet's procedure. Instead of letting volunteers decide when to move, Trevena and Miller (2010) asked them to wait for an audio tone before deciding whether to tap a key. If Libet's interpretation were correct, the RP should be greater after the tone when a person chose to tap the key. While there was an RP before volunteers made their decision to move, the signal was the same whether or not they elected to tap. Miller concludes that the RP may merely be a sign that the brain is paying attention and does not indicate that a decision has been made. They also failed to find evidence of subconscious decision-making in a second experiment. This time they asked volunteers to press a key after

the tone, but to decide on the spot whether to use their left or right hand. As movement in the right limb is related to the brain signals in the left hemisphere and vice versa, they reasoned that if an unconscious process is driving this decision, where it occurs in the brain should depend on which hand is chosen, but they found no such correlation.

Schurger and colleagues (2012) have a key explanation. Previous studies have shown that, when we have to make a decision based on sensory input, assemblies of neurons start accumulating evidence in favour of the various possible outcomes. The team reasoned that a decision is triggered when the evidence favouring one particular outcome becomes strong enough to tip the dynamics – i.e. when the neural noise generated by random or chaotic activity accumulates sufficiently so that its associated assembly of neurons crosses a threshold tipping point. The team repeated Libet's experiment, but this time if, while waiting to act spontaneously, the volunteers heard a click they had to act immediately. The researchers predicted that the fastest response to the click would be seen in those in whom the accumulation of neural noise had neared the threshold - something that would show up in their EEG as a readiness potential. In those with slower responses to the click, the readiness potential was indeed absent in the EEG recordings. *"We argue that what looks like a pre-conscious decision process may not in fact reflect a decision at all. It only looks that way because of the nature of spontaneous brain activity."* Schurger and Uithol (2015) specifically note the evidence of a sensitively dependent butterfly effect (London et al. 2010) as a reason why nervous systems vary their responses on identical stimuli as an explanation for why it could be impossible to set out a deterministic decision making path from contributory systems to a conscious decision, supporting their stochastic accumulator model. Hans Liljenström (2021) using stochastic modelling concludes that if decisions have to be made fast, emotional processes and aspects dominate, while rational processes are more time consuming and may result in a delayed decision.

Alexander et al. (2016) establish the lack of linkage of the RP to motor activity:

"The results reveal that robust RPs occurred in the absence of movement and that motor-related processes did not significantly modulate the RP. This suggests that the RP measured here is unlikely to reflect preconscious motor planning or preparation of an ensuing movement, and instead may reflect decision-related or anticipatory processes that are non-motoric in nature."

More recently the actual basis coordinating a decision to act has been found to reside in slowly evolving dopamine modulation. When you reach out to perform an action, seconds before you voluntarily extend your arm, thousands of neurons in the motor regions of your brain erupt in a pattern of electrical activity that travels to the spinal cord and then to the muscles that power the reach. But just prior to this massively synchronised activity, the motor regions in your brain are relatively quiet. For such self-driven movements, a key piece of the "go" signal that tells the neurons precisely when to act has been revealed in the form of slow ramping up of dopamine in a region deep below the cortex which closely predicted the moment that mice would begin a movement — seconds into the future (Hamilos et al. 2021).

The authors imaged mesostriatal dopamine signals as mice decided when, after a cue, to retrieve water from a spout. Ramps in dopamine activity predicted the timing of licks. Fast ramps preceded early retrievals, slow ones preceded late ones. Surprisingly, dopaminergic signals ramped-up over seconds between the start-timing cue and the self-timed movement, with variable dynamics that predicted the movement/reward time on single trials. Steeply rising signals preceded early lick-initiation, whereas slowly rising signals preceded later initiation. Higher baseline signals also predicted earlier self-timed movements. Consistent with this view, the dynamics of the slowly evolving endogenous dopaminergic signals quantitatively predicted the moment-by-moment probability of movement initiation on single trials. The authors propose that ramping dopaminergic signals, likely encoding dynamic reward expectation, can modulate the decision of when to move.

Slowly varying neuromodulatory signals could allow the brain to adapt to its environment. Such flexibility wouldn't be afforded by a signal that always led to movement at the exact same time. Allison Hamilos notes: *"The animal is always uncertain, to some extent, about what the true state of the world is. You don't want to do things the same way every single time — that could be potentially disadvantageous."*

This introduces further complexity into the entire pursuit of Libet's readiness potential, which is clearly not itself the defining event, which rather is at first call concealed in a slowly varying dopamine modulation, which in itself does not determine the timing of the event except on a probabilistic basis. Furthermore the striatum itself is a gatekeeper in the basal ganglia for coordinating the underlying conscious decision to act and not the conscious decision itself.

Celia Green and Grant Gillett (1995) have also cited three grounds for the readiness potential to be unreliable:

First, there is a dual assumption that an intention is the kind of thing that causes an action and that can be accurately introspected. Second, there is a real problem with the method of timing the mental events concerned given that Libet himself has found the reports of subjects to be unreliable in this regard. Third, there is a suspect assumption that there are such things as timable and locatable mental and brain events accompanying and causing human behaviour.

Catherine Reason (2016), drawing on Caplain (1996, 2000) and Luna (2016), presents an intriguing logical proof that computing machines, and by extension physical systems, can never be certain if they possess conscious awareness, undermining the principal of computational equivalence (Wolfram 2002, 2021):

An omega function is any phi-type function which can be performed, to within a quantified level of accuracy, by some conscious system. A phi-type function is any mapping which associates the state of some system with the truth value of some proposition. This significance of this is that it can be shown that no purely physical system can perform any phi-type function to within any quantified level of accuracy, if that physical system is required to be capable of humanlike reasoning.

The proof is as follows: Let us define a physical process as some process whose existence is not dependent on some observation of that process. Now let X be the set of all physical processes necessary to perform any phi-type function. Since the existence of X is not dependent on any given observation of X, it is impossible to be sure empirically of the existence of X. If it is impossible to be sure of the existence of X, then it is impossible to be sure of the accuracy of X. If it is impossible to be sure of the accuracy of X, then it is impossible to be sure that X correctly performs the phi-type function it is supposed to perform. Since any system capable of humanlike reasoning can deduce this, it follows that no physical system capable of humanlike reasoning can perform any phi-type function without becoming inconsistent.

Counterintuitively, this implies that human consciousness is associated with a violation of energy conservation. It also provides another objection to Libet:

“even if the readiness potential can be regarded as a predictor of the subject’s decision in a classical system, it cannot necessarily be regarded as such in a quantum system. The reason is that the neurological properties underlying the readiness potential may not actually have determinate values until the subject becomes consciously aware of their decision”.

In subsequent papers (Reason 2019, Reason & Shah 2021) she expands this argument:

I identify a specific operation which is a necessary property of all healthy human conscious individuals — specifically the operation of self-certainty, or the capacity of healthy conscious humans to “know” with certainty that they are conscious. This operation is shown to be inconsistent with the properties possible in any meaningful definition of a physical system.

In an earlier paper, using a no-go theorem, it was shown that conscious states cannot be comprised of processes that are physical in nature (Reason, 2019). Combining this result with another unrelated work on causal emergence in physical systems (Hoel, Albantakis and Tononi, 2013), we show in this paper that conscious macrostates are not emergent from physical systems and they also do not supervene on physical microstates.

Pivotal in a forthcoming formalisation of the argument, Reason (2023) cites Descartes’ “cogito ergo sum” as counter example requiring human consciousness so the success of her theorem also frees Cartesian duality from Ryle’s deathly grip.

In a counterpoint to this Travers et al. (2020) suggest the RP is associated with learning and thus reflects motor planning or temporal expectation, but neither planning nor expectation inform about the timing of a decision to act:

“Participants learned through trial and error when to make a simple action. As participants grew more certain about when to act, and became less variable and stochastic in the timing of their actions, the readiness potential prior to their actions became larger in amplitude. This is consistent with the proposal that the RP reflects motor planning or temporal expectation. ... If the RP reflects freedom from external constraint, its amplitude should be greater early in learning, when participants do not yet know the best time to act. Conversely, if the RP reflects planning, it should be greater later on, when participants have learned, and know in advance, the time of action. We found that RP amplitudes grew with learning, suggesting that this neural activity reflects planning and anticipation for the forthcoming action, rather than freedom from external constraint.”

Fifel (2018) reviewing the state of the current research described the following picture:

Results from Emmons et al. (2017) suggest that such ramping activity encodes self-monitored time intervals. This hypothesis is particularly pertinent given that self-monitoring of the passing of time by the experimental subjects is intrinsic to the Libet et al. (1983) experiment. Alternatively, although not mutually exclusive, RP might reflect general anticipation (i.e., the conscious experience that an event will soon occur) (Alexander et al., 2016) or simply background neuronal noise (Schurger et al., 2016). Future

studies are needed to test these alternatives. ... Consequently, we might conclude that: Neuroscience may in no way interfere with our first-person experience of the will, it can in the end only describe it ... it leaves everything as it is.

The difficulty of the hard problem, which remains unresolved 26 years later, is also tied to the likewise unresolved problem of assumed causal closure of the universe in brain function at the basis of pure materialistic neuroscience. Until it is empirically confirmed it remains simply a matter of opinion that has grown into a belief system academically prejudiced against hypotheses not compliant with the physical materialistic weltanschauung.

While some neuroscientists (Johnson 2020) imply the hard problem is not even a scientific question, the neuroscience concept of causal closure (Chalmers 2015) based on classical causality, or quantum correspondence to it, not only remains empirically unverified in the light of Libet, Schurger and others, but it is unclear that a convincing empirical demonstration is even possible, or could be, given the fact that neuronal feedback processes span all scales from the organism to the quantum uncertain realm and the self-organised criticality of brain dynamics. Finally, it is in manifest conflict with all empirical experience of subjective conscious volitional intent universal to sane human beings.

As Bernard Baars commented in conversation:

I don't think science needs to, or CAN prove causal closure, because what kind of evidence will prove that? We don't know if physics is "causally closed," and at various times distinguished physicists think they know the answer, but then it breaks down. The Bertrand Russell story broke down, and the Hilbert program in math, and ODEs, and the record is not hopeful on final solutions showing a metaphysically closed system .

The status of the neuroscience perspective of causal closure has led to an ongoing debate about the efficacy of human volition and the status of free will (Nahamias 2008, Mele, 2014), however Joshua Shepherd (2017) points out, that the neuroscientific threat to free will has not been causally established, particularly in the light of Schurger et al. (2015).

For this reason, in treating the hard problem and volitional intent, I will place the onus on proof on materialism to demonstrate itself and in defence of volition have simply outlined notable features of central nervous processing, consistent with an in principle capacity to operate in a quantum-open state of seamless partial causal closure involving subjectively conscious efficacy of volitional will physically in decision-making (in the brain) and behaviour (in the world). From this point of view, efficacy of volition is itself a validated empirical experience which is near universal to sane conscious humans, thus negating causal closure by veridical affirmation in the framework of symbiotic existential cosmology, where empirical experience has equally valid cosmological status to empirical observation. Libet's experiment purported to demonstrate an inconsistency, by implying the brain had already made a decision before the conscious experience of it, but Trevena and Miller and Schurger's team have deprecated this imputation.

Emergence, Weak, Edge-of-chaos and Strong

Key to the question of conscious volition is the profound difference between the notions of strong and weak emergence. Turkheimer et al. (2019) spell out the difference between these two:

Modern Emergence can be divided into two epistemological types: strong and weak. A system is said to exhibit strong emergence when its behaviour, or the consequence of its behaviour, exceeds the limits of its constituent parts. Thus the resulting behavioural properties of the system are caused by the interaction of the different layers of that system, but they cannot be derived simply by analysing the rules and individual parts that make up the system. Weak emergence on the other hand, differs in the sense that whilst the emergent behaviour of the system is the product of interactions between its various layers, that behaviour is entirely encapsulated by the confines of the system itself, and as such, can be fully explained simply through an analysis of interactions between its elemental units.

They note that the kind of emergence that surfaced first in the neurosciences was greatly shaped by earlier work of Roger Sperry (1980), who proposed a view of the brain characterised by a strong top-down organisational component. Sperry was adamant that his model did not imply any form of mind brain dualism nor a parallel existence of neurobiological and mental processes, but that, after emergence, mental processes would take over and exert control down to the cellular level:

It is the idea, in brief, that conscious phenomena as emergent functional properties of brain processing exert an active control role as causal detents in shaping the flow patterns of cerebral excitation. Once generated from neural events, the higher order mental patterns and programs have their own subjective qualities and progress, operate and interact by their own causal laws and principles which are different from and cannot be reduced to those of neurophysiology.

Emergence is not just an assumed property of human brains but applies more generally to systems notions of the emergence of living systems generally including ideas like autopoiesis and the question of whether biological laws are entirely reductionist or form more general fundamental constraint on the behaviour of natural systems.

Physical materialism rejects any form of strong emergence that asserts known physical laws can somehow be overridden by mental processes. For example weak emergence allows for a reductionistic computational paradigm of brain dynamics to putatively replicate the functional agency of an autonomous system through feedback processes between the environment and the organism, so that any purely physicalist descriptions, from artificial intelligence, to ideas like Dennett's multiple drafts model of consciousness, in the next section fit within the pure physicalist regime.

Symbiotic Existential Cosmology invokes primal subjectivity as a foundational cosmological complement to the physical universe that is optimately compliant with physical boundary conditions, and so poses no conflicts between subjective panpsychic qualia and empirical physics and neuroscience, but it is not a form of passive mentalism (Carroll 2021) as it is conceived as interacting with physical uncertainty. It also cites the eucaryote endo-symbiosis as an emergent topological transition, in which the excitable membrane and neurotransmitter-based social signalling in single celled species, enabled the form of subjective conscious sentience and volition we see in all eucaryotes today.

This emergent transition sits right on the boundary between strong and weak emergence, as a form of quantum edge of chaos emergence that affirms subjective conscious volition. Having efficacy over the physical universe, in much the same way Sperry originally cited in 1980, but without claiming to violate established physical laws. This is because it focuses on the indeterminacy of the quantum universe and collapse of the wave function in biological systems as a key avenue through which subjective conscious volition can be physically efficacious and yet consistent with the known laws of physics, by citing interpretations such as transactional super-causality and super-determinism to provide processes below the classical level to both explain quantum indeterminacy and conscious intentional will in one step, without violating the Born probability interpretation.

Hopeful Monsters 1: Virtual Machines v Cartesian Theatres

Reductionistic descriptions attempting to explain subjective experience objectively frequently display similar pitfalls to creationist descriptions of nature, and those in Biblical Genesis, which project easy, familiar concepts, such as human manufacture breath, or verbal command onto the natural universe.

Paul Churchland (1985) makes a definitive play for a reductionistic paradigm based on promissory materialism, that the emerging neuroscience description will eclipse and supplant our subjective "folk psychology" views of conscious experience in a utopian vision of neuroscience ascendent:

Consider now the possibility of learning to describe, conceive, and introspectively apprehend the teeming intricacies of our inner lives within the conceptual framework of a matured neuroscience, a neuroscience that successfully reduces, either smoothly or roughly, our common-sense folk psychology. Suppose we trained our native mechanisms to make a new and more detailed set of discriminations, a set that corresponded not to the primitive psychological taxonomy of ordinary language, but to some more penetrating taxonomy of states drawn from a completed neuroscience. And suppose we trained ourselves to respond to that reconfigured discriminative activity with judgments that were framed, as a matter of course, in the appropriate concepts from neuroscience.'

If the examples of the symphony conductor (who can hear the Am7 chords), the oenologist (who can see and taste the glycol), and the astronomer (who can see the temperature of a blue giant star) provide a fair parallel, then the enhancement in our introspective vision could approximate a revelation. Dopamine levels in the limbic system, the spiking frequencies in specific neural pathways, resonances in the nth layer of the occipital cortex, inhibitory feed-back to the lateral geniculate nucleus, and countless other neuro-physical niceties could be moved into the objective focus of our introspective discrimination, just as Gm7 chords and Adim chords are moved into the objective focus of a trained musician's auditory discrimination. We will of course have to learn the conceptual framework of a matured neuroscience in order to pull this off. And we will have to practice its non-inferential application. But that seems a small price to pay for the quantum leap in self-apprehension.

All of this suggests that there is no problem at all in conceiving the eventual reduction of mental states and properties to neurophysiological states and properties. A matured and successful neuroscience need only include, or prove able to define, a taxonomy of kinds with a set of embedding laws that faithfully mimics the taxonomy and causal generalizations of folk psychology. Whether future neuro-scientific theories will prove able to do this is a wholly empirical question, not to be settled a priori. The evidence for a positive answer is substantial and familiar, centering on the growing explanatory success of the several neurosciences.

But there is negative evidence as well: I have even urged some of it myself ("Eliminative Materialism and the Propositional Attitudes," op. cit.). My negative arguments there center on the explanatory and predictive poverty of folk psychology, and they question whether it has the categorical integrity to merit the reductive preservation of its familiar ontology. That line suggests substantial revision or outright elimination as the eventual fate of our mentalistic ontology. The qualia-based arguments of Nagel, Jackson, and Robinson, however, take a quite different line. They find no fault with folk psychology. Their concern is with the explanatory and descriptive poverty of any possible neuroscience, and their line suggests that emergence is the correct story for our mentalistic ontology. Let us now examine their arguments.

John Searle (1980) devised his famous "Chinese Room" as a counterexample to machine having consciousness and intentionality. He supposed that artificial intelligence research had succeeded in constructing a computer large language model that behaves as if it understands Chinese, just as chatGPT now does and that it performs its task so convincingly that it comfortably passes the Turing test, convincing a human Chinese speaker that the program is itself a live Chinese speaker. Searle then uses the English version of the algorithm to replicate its performance manually in Chinese without being aware in "mind", "understanding", or "consciousness", of the actual language responses or their meaning, thus demonstrating that even though intentionality in human beings (and animals) may be an empirical product of causal features about the relations between mental processes and brains, running a computer program is never by itself a sufficient condition of intentionality. The argument is directed against the philosophical functionalism and computationalism, which hold that the mind may be viewed as an information-processing system operating on formal symbols, and that simulation of a given mental state is sufficient for its presence.

P & P Churchland (1981) in response, present a bleak landscape of the mind, lacking any intentionality over a machine:

Functionalism - construed broadly as the thesis that the essence our psychological states resides in the abstract causal roles they play in a complex economy of internal states mediating environment inputs and behavioral outputs - seems to us to be free from any fatal or essential shortcomings ... The correct strategy is to argue that our own mental states are just as innocent of "intrinsic intentionality" as are the states of any machine simulation. On our view, all ascriptions of meaning or propositional content are relative - in senses to be explained. The notion of "intrinsic intentionality" (Searle 1980) makes no more empirical sense than does the notion of position in absolute space.

In his reductionist account in "Consciousness Explained" Daniel Dennett (1991) cites his "multiple drafts" model of brain processing, as a case of evolutionary competition among competing neural assemblies, lacking overall coherence, thus bypassing the need for subjective consciousness. This exposes a serious problem of conceptual inadequacy with reductionism. Daniel is here writing his book using the same metaphors as the very activities he happens to be using – the message is thus the medium. He can do this as a subjectively conscious being only by suppressing the significance of virtually every form of coherent conscious experience around him, subjugating virtually all features of his conscious existence operating for 100% of his conscious life, in favour of a sequence of verbal constructs having little more explanatory value than a tautology. This is what I call the psychosis of reductionistic materialism, which is shared by many AI researchers and cognitive scientists.

Despite describing the mind as a virtual machine, Dennett & Kinsbourne (1995) do concede a conscious mind exists at least as an observer:

"Wherever there is a conscious mind, there is a point of view. A conscious mind is an observer, who takes in the information that is available at a particular (roughly) continuous sequence of times and places in the universe. ... It is now quite clear that there is no single point in the brain where all information funnels in, and this fact has some far from obvious consequences."

But neuroscience has long ceased talking about a single point or single brain locus responsible for consciousness, which is associated with coherent "in phase" activity as a whole. Nevertheless Dennett attempts to mount a lethal attack on any coherent manifestation of subjectivity, asserting there is no single, constitutive "stream of consciousness":

"The alternative, Multiple Drafts model holds that whereas the brain events that discriminate various perceptual contents are distributed in both space and time in the brain, and whereas the temporal properties of these various events are determinate, none of these temporal properties determine subjective order, since there is no single, constitutive "stream of consciousness" but rather a parallel stream of conflicting and continuously revised contents" (Dennett & Kinsbourne (1995).

"There is no single, definitive "stream of consciousness," because there is no central Headquarters, no Cartesian Theatre where "it all comes together" for the perusal of a Central Meaner. Instead of such a single stream (however wide), there are multiple channels in which specialist circuits try, in parallel pandemoniums, to do their various things, creating Multiple Drafts as they go. Most of these fragmentary drafts of "narrative" play short-lived roles in the modulation of current activity but some get promoted to further functional roles, in swift succession, by the activity of a virtual machine in the brain. The seriality of this machine (its "von

Neumannesque" character) is not a "hard-wired" design feature, but rather the upshot of a succession of coalitions of these specialists." (Dennett 1991)

However we know and shall discuss in the context of the default mode network in the context of psychedelics, the balance between top-down processes of control and integration, against just such a flood of competing regional bottom-up excitations, which become more able to enter consciousness, because of lowered barriers under the drug.

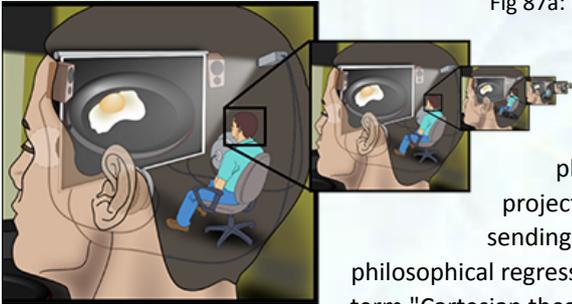

Fig 87a: Homunculus argument infinite regress.

Dennett says that, when the dualism is removed, what remains of Descartes' interactionist model amounts to imagining a tiny theatre in the brain where a homunculus (small person), now physical, performs the task of observing all the sensory data projected on a screen at a particular instant, making the decisions and sending out commands. The homunculus argument cites this as a philosophical regress which doesn't solve the problem but recurses it ad infinitum. The term "Cartesian theatre" was brought up in the context of the multiple drafts model that Dennett posits in *Consciousness Explained* (1991 107):

Cartesian materialism is the view that there is a crucial finish line or boundary somewhere in the brain, marking a place where the order of arrival equals the order of "presentation" in experience because what happens there is what you are conscious of. ... Many theorists would insist that they have explicitly rejected such an obviously bad idea. But ... the persuasive imagery of the Cartesian Theater keeps coming back to haunt us—laypeople and scientists alike—even after its ghostly dualism has been denounced and exorcized.

Yet the ghost Dennett claims to have crushed just keeps coming back to haunt him.

Bernard Baars' (1997) global workspace theory, in the form of the actors in the "Cartesian theatre" of consciousness, is creatively provocative of the psyche, and concedes a central role for consciousness. His approach suggests that consciousness is associated with the whole brain, in integrated coherent activity and is thus a property of the brain as a whole functioning entity, in relation to global workspace, rather than arising from specific subsystems.

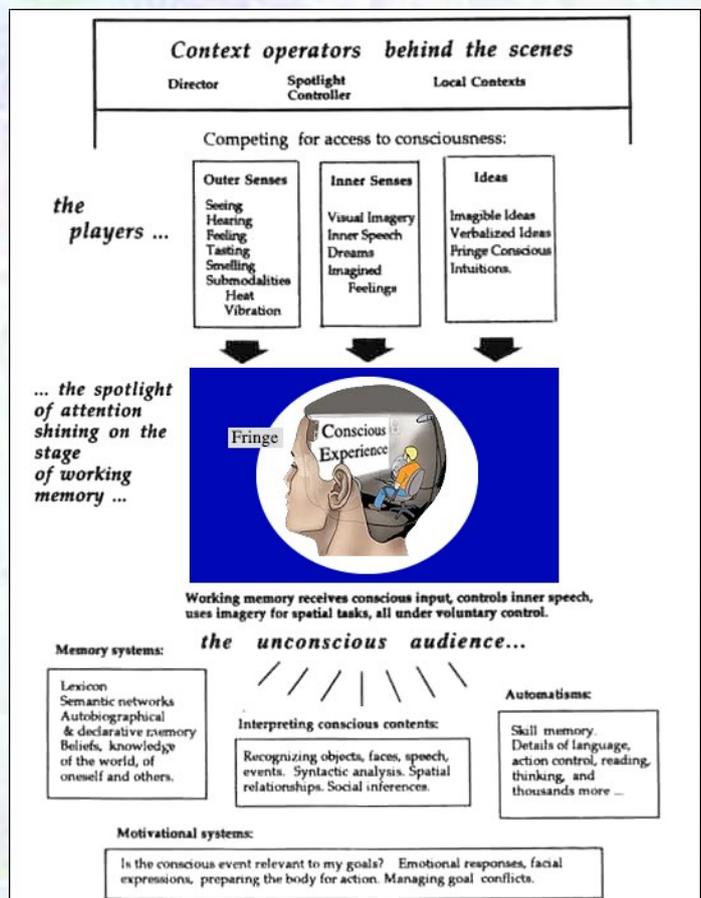

Furthermore, the approach rather neatly identifies the distinction between unconscious processing and conscious experience, in the spotlight of attention, accepts conscious experience as a central arena consistent with whether a given dynamic is confined to asynchronous regional activity or is part of a coherent global response.

Fig 87 Baars' (1997) view of the Cartesian theatre of consciousness has genuine explanatory power about the easy problem of the relation between peripheral unconscious processing and integrated coherent states associated with consciousness.

But again this description is an imaginative representation of Descartes' homunculus in the guise of a Dionysian dramatic production, so it is also a projection onto subjective consciousness, albeit a more engaging one.

Lenore and Manuel Blum (2021) have developed a theoretical model of conscious awareness designed in relation to Baars' global workspace theory that applies as much to a computer as an organism:

Our view is that consciousness is a property of all properly organized computing systems, whether made of flesh and blood or metal and silicon. With this in mind, we give a simple abstract substrate-independent computational

model of consciousness. We are not looking to model the brain nor to suggest neural correlates of consciousness, interesting as they are. We are looking to understand consciousness and its related phenomena.

Essentially the theory builds on the known feedbacks between peripheral unconscious processing and short term memory and the spotlight of conscious attention, paraphrasing these in purely computational terms, utilising a world model that is updated, notions corresponding to "feelings" and even "dream creation", in which a sleep processor alters the modality of informational chunking.

While it is possible to conceive of such analogous models it remains extremely unlikely that any such computational model can capture the true nature of subjective consciousness. By contrast with a Turing machine which operates discretely and serially on a single mechanistic scale, biological neurosystems operate continuously and discretely on fractal scales from the quantum level through molecular, subcellular dynamics up to global brains states, so it remains implausible in the extreme that such computational systems however complex in structural design can replicate organismic subjective consciousness. The same considerations apply to artificial neural net designs which lack the fractal edge of chaos dynamic of biological neurosystems.

Another discovery pertinent here (Fernandino et al. (2022)) is that a careful neuroscientific study has found that lexical semantic information can be reliably decoded from a wide range of heteromodal cortical areas in the frontal, parietal, and temporal cortex, but that in most of these areas, they found a striking advantage for experience-based representational structures (i.e., encoding information about sensory-motor, affective, and other features of phenomenal experience), with little evidence for independent taxonomic or distributional organisation. This shows that experience is the foundational basis for conceptual and cognitive thought, giving it a primary universal status over rational or verbal thought.

Jo Edwards in personal communication notes that Peter Slezak (2023) claims that many of the current theories of mind already discussed, suffer from abstract versions of the homunculus regress due to invoking a universal Spectator:

I have greatly enjoyed reading Peter Slezak's new book Spectator in the Cartesian Theater. He says the flaw in so many arguments about mind, often present in both sides of many interminable debates about mind, is the illegitimate invocation of an intelligent Spectator. Everyone is aware of the danger of positing a God's eye view. Slezak is saying that even more pernicious is the assumption of an intelligent or omniscient Spectator view in which we use our own external powers to explain the internal mechanisms of another case of those same powers. A simple example is that many modern theories of mind, rather than positing an illegitimate 'homunculus' to solve the insoluble, posit a dynamic schema that would need such a homunculus to work but deny there is any homunculus, instead using the powers of the external spectator to do the magic. So theories from Tononi, Dehaene, Crick, Kosslyn, McFadden, Fodor, Millikan, you name it, all in one way or another commit the true 'homunculus fallacy' by tacitly trying to explain the inside workings of an intelligent mind by slipping another intelligent mind's powers inside.

Consciousness and Broad Integrated Processing: The Global Neuronal Workspace (GNW) model

Stanislas Dehaene and Jean-Pierre Changeux (2008, 2011) have combined experimental studies and theoretical models, including Baars' global workspace theory to address the challenge of establishing a causal link between subjective conscious experience and measurable neuronal activity in the form of the Global Neuronal Workspace (GNW) model according to which conscious access occurs when incoming information is made globally available to multiple brain systems through a network of neurons with long-range axons densely distributed in prefrontal, parieto-temporal, and cingulate cortices.

Converging neuroimaging and neurophysiological data, acquired during minimal experimental contrasts between conscious and non-conscious processing, point to objective neural measures of conscious access: late amplification of relevant sensory activity, long-distance cortico-cortical synchronization at beta and gamma frequencies, and 'ignition' i.e. "lighting up" of a large-scale prefronto-parietal network. By contrast, as shown in fig 86, states of reduced consciousness have large areas of cortical metabolic deactivation. In conclusion, the authors look ahead to the quest of understanding the conscious brain and what it entails:

The present review was deliberately limited to conscious access. Several authors argue, however, for additional, higher-order concepts of consciousness. For Damasio and Meyer (2009), core consciousness of incoming sensory information requires integrating it with a sense of self (the specific subjective point of view of the perceiving organism) to form a representation of how the organism is modified by the information; extended consciousness occurs when this representation is additionally related to the memorized past and anticipated future (see also Edelman, 1989). For Rosenthal (2004), a higher-order thought, coding for the very fact that the organism is currently representing a piece of information, is needed for that information to be conscious. Indeed, metacognition, or

the ability to reflect upon thoughts and draw judgements upon them is often proposed as a crucial ingredient of consciousness. In humans, as opposed to other animals, consciousness may also involve the construction of a verbal narrative of the reasons for our behavior (Gazzaniga et al., 1977).

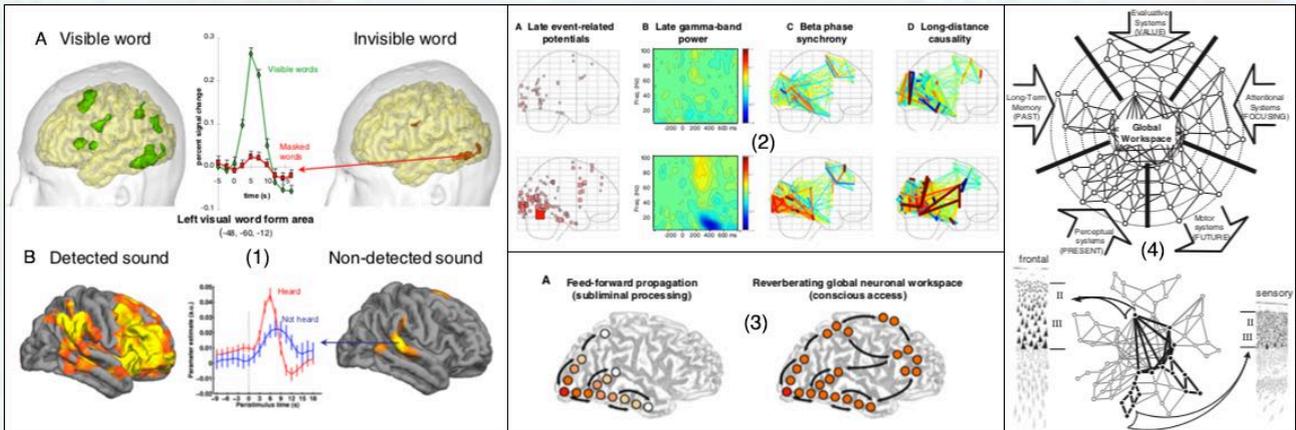

Fig 88: Both fMRI (1) and (2) EEG/MEG data, show broad activation across diverse linked cortical regions, when non-conscious processing rises to the conscious level. Likewise local feed forward propagation (3) leads to reverberating cortical connections. These influences are combined in the GRW model (4) in which Baars' global workspace theatre becomes a more precisely defined model attempting to solve several of the easier problems of consciousness into a globally resonant network theory.

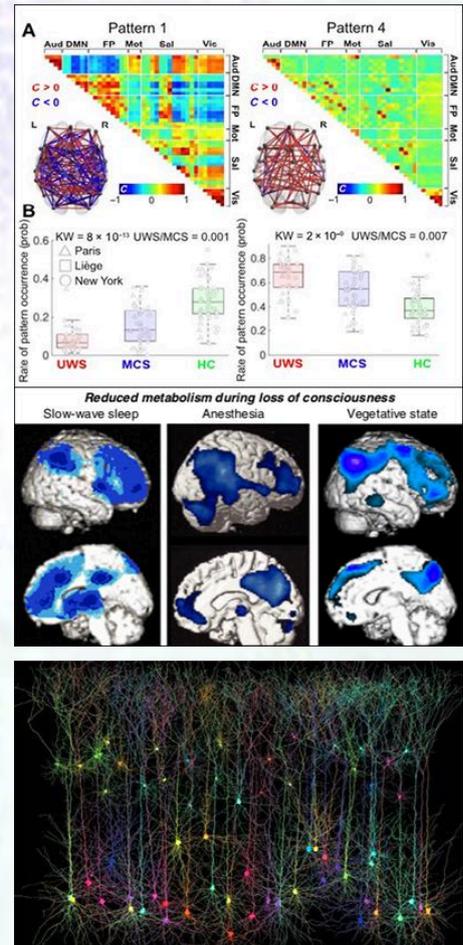

In the future, as argued by Haynes (2009), the mapping of conscious experiences onto neural states will ultimately require not only a neural distinction between seen and not-seen trials, but also a proof that the proposed conscious neural state actually encodes all the details of the participant's current subjective experience. Criteria for a genuine one-to-one mapping should include verifying that the proposed neural state has the same perceptual stability (for instance over successive eye movements) and suffers from the same occasional illusions as the subject's own report.

However, decoding the more intermingled neural patterns expected from PFC and other associative cortices is clearly a challenge for future research. Another important question concerns the genetic mechanisms that, in the course of biological evolution, have led to the development of the GNW architecture, particularly the relative expansion of PFC, higher associative cortices, and their underlying long-distance white matter tracts in the course of hominization. Finally, now that measures of conscious processing have been identified in human adults, it should become possible to ask how they transpose to lower animal species and to human infants and fetuses.

In "A better way to crack the brain", Mainen, Häusser & Pouget (2016) cite novel emerging technologies such as optogenetics as tools likely to eclipse the overriding emphasis on electrical networking data, but at the same time illustrate the enormity of the challenge of neuroscience attempting to address consciousness as a whole.

Some sceptics point to the teething problems of existing brain initiatives as evidence that neuroscience lacks well-defined objectives, unlike high-energy physics, mathematics, astronomy or genetics. In our view, brain science, especially systems neuroscience (which tries to link the activity of sets of neurons to behaviour) does not want for bold, concrete goals. Yet large-scale initiatives have tended to set objectives that are too vague and not realistic, even on a ten-year timescale.

Fig 89-90: Top: Conscious brain states are commonly associated with phase correlated global cortical activity. Conscious brain activity in healthy controls is contrasted with diminished cortical connectivity of excitation in unaware and minimally conscious states (Demertzi et al. 2019). Bottom: Reduced metabolism during loss of consciousness (Dehaene & Changeux J 2011). See also Melloni et al. (2007). Optogenetic images of pyramidal cells in a rodent cortex.

Several advances over the past decade have made it vastly more tractable to solve fundamental problems such as how we recognize objects or make decisions. Researchers can now monitor and manipulate patterns of activity in large neuronal ensembles, thanks to new technologies in molecular engineering, micro-electronics and computing. For

example, a combination of advanced optical imaging and optogenetics can now read and write patterns of activity into populations of neurons. It is also possible to relate firing patterns to the biology of the neurons being recorded, including their genetics and connectivity.

However none of these are coming even close to stitching together a functional view of brain processing that comes anywhere near to solving the hard problem, or even establishing causal closure, given the extreme difficulty of verifying classical causality in every brain process and the quantum nature of all brain processes at the molecular level. Future prospects for solving the hard problem via the easy ones thus remain unestablished.

Hopeful Monster 2: Consciousness and Surviving in the Wild v Attention Schema Theory

Real world survival problems in the open environment don't necessarily have a causally-closed or even a computationally tractable solution, due to exponential runaway like the travelling salesman problem, thus requiring sensitive dependence on the butterfly effect and intuitive choices. Which route should the antelope take to reach the water hole when it comes to the fork in the trail? The shady path where a tiger might lurk, or the savannah where there could be a lion in the long grass? All the agents are conscious sentient beings using innovation and stealth and so computations depending on reasoned memory are unreliable because the adversaries can also adapt their strategies and tactics to frustrate the calculations. The subtlest sensory hints of crisis amid split-second timing is also pivotal.

There is thus no tractable solution. Integrated anticipatory intuition, combined with a historical knowledge of the terrain, appears to be the critical survival advantage of sentient consciousness in the prisoners' dilemma of survival, just as sexuality is, in the Red Queen race (Ridley 1996) between hosts and parasites. This coherent anticipation possessed by subjective consciousness appears to be the evolutionary basis for the emergence and persistence of subjective consciousness as a quantum-derived form of anticipation of adventitious risks to survival, not cognitive processes of verbal discourse.

Anil Seth (2021) notes: *We are not the beast machines of Descartes, for whom life was irrelevant to mind. It is exactly the opposite. Brains are not for rational thinking, linguistic communication, or perceiving the world. Consciousness has more to do with being alive than with being intelligent. Experiences of being you, or of being me, emerge from the way the brain predicts and controls the internal state of the body. The essence of selfhood is neither a rational mind nor an immaterial soul. It is a deeply embodied biological process, a process that underpins the simple feeling of being alive that is the basis for all our experiences of selfhood ... Our conscious experiences of the world around us, and of ourselves within it, happen with, through, and because of our living bodies. Our animal constitution is not merely compatible with our conscious perceptions of self and world. We cannot understand the nature and origin of these conscious experiences, except in light of our nature as living creatures. ... Every self that ever was is complex and multifaceted, composed of many different aspects that seem bound together as a unified whole. But to grasp the essence of being a self, we must cast off the outer layers and go deep within the body.*

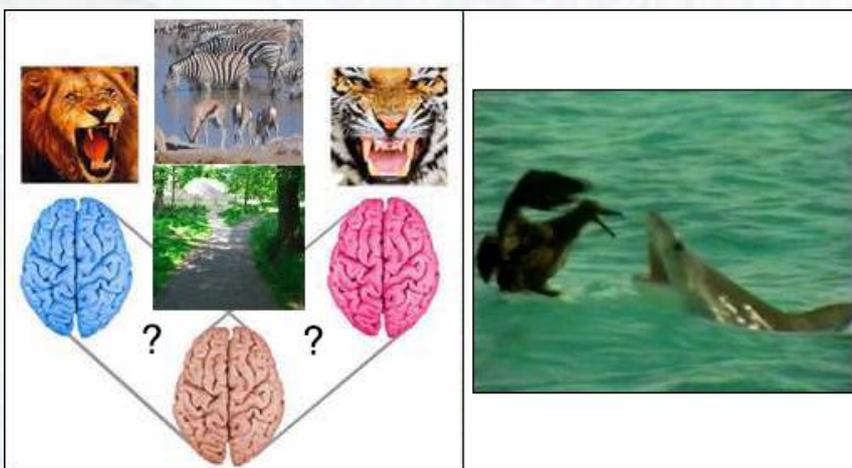

Fig 91: Which route should the human or antelope take to reach the water hole when it comes to the fork in the trail? The shady path where a tiger might lurk, or the savannah where there could be a lion in the long grass? Real world survival problems require intuitive multi-option decisions, creativity and often split-second timing requiring anticipatory consciousness. Thus modelling the existence of subjective consciousness or otherwise based only on causal concepts and verbal reasoning processes gives a false evolutionary and cosmological view. Here is where the difference between a conscious organism and an AI robot attempting to functionally emulate it is laid bare in

tooth and claw. Although only about 23,000 lions remain in sub-Saharan Africa, about 250 people a year die in lion attacks. An estimated 500 people a year are killed in hippo attacks, and snake bites kill anywhere from 7,000 to 32,000 people a year (CNN).

Michael Graziano's (2016, 2017, Webb & Graziano 2015), attention schema theory, or AST, self-described as a mechanistic account of subjective awareness which emerged in parallel with my own work (King 2014), gives an

account of the evolutionary developments of the animal brain, taking account of the adaptive processes essential for survival to arrive at the kind of brains and conscious awareness we experience:

“We propose that the top–down control of attention is improved when the brain has access to a simplified model of attention itself. The brain therefore constructs a schematic model of the process of attention, the ‘attention schema,’ in much the same way that it constructs a schematic model of the body, the ‘body schema.’ The content of this internal model leads a brain to conclude that it has a subjective experience – a non-physical, subjective awareness and assigns a high degree of certainty to that extraordinary claim”.

However, in Graziano (2013, 2019), he advocates illusionism the idea that subjective consciousness and volitional will are a self-fulfilling evolutionary delusion, so that the author believes AST as a purely mechanistic principle could in principle be extended to a machine without the presence of subjective consciousness: *“Such a machine would “believe” it is conscious and act like it is conscious, in the same sense that the human machine believes and acts”.*

It remains unclear that a digital computer, or AI process can achieve this notwithstanding chatGPT. Ricci et al. (2021) note in concluding remarks towards one of the most fundamental and elementary tasks, abstract same-different discrimination: *The aforementioned attention and memory network models are stepping stones towards the flexible relational reasoning that so epitomizes biological intelligence. However, current work falls short of the — in our view, correct — standards for biological intelligence set by experimentalists like Delius (1994) or theorists like Fodor (1988).*

Yet AST is a type of filter theory similar to Huxley’s ideas about consciousness, so it invokes a principle of neural organisation that is consistent with and complementary to subjective consciousness: *“Too much information constantly flows in to be fully processed. The brain evolved increasingly sophisticated mechanisms for deeply processing a few select signals at the expense of others, and in the AST, consciousness is the ultimate result of that evolutionary sequence.”*

The overall idea of a purely physical internal model of reality representing its own attention process, thus enabling it to observe itself, is an astute necessary condition for the sort of subjective consciousness we find in the spread of metazoa, but it is in no way sufficient to solve the hard problem or address any more than the one easy problem it addresses, about recursive attention. However its description, of fundamental changes in overall brain architecture summarised in Graziano (2016) highlights the actual evolutionary forces shaping the development of the conscious mind lie in the paranoia of survival the jungle as noted in fig 91, rather than the verbal contortions of philosophical discourse:

*“If the wind rustles the grass and you misinterpret it as a lion, no harm done.
But if you fail to detect an actual lion, you’re taken out of the gene pool” (Michael Graziano 2016).*

However Graziano (2020), in claiming why AST “has to be right”, commits to de-subjectifying consciousness in favour of an AI analysis of recursive attention systems. In relation to the reality of consciousness in his words, the claim that: *“I have a subjective, conscious experience. It’s real; it’s the feeling that goes along with my brain’s processing of at least some things. I say I have it and I think I have it because, simply, I do have it. Let us accept its existence and stop quibbling about illusions”*, he attempts a structural finesse based on recursive attention:

Suppose the brain has a real consciousness. Logically, the reason why we intuit and think and say we have consciousness is not because we actually have it, but must be because of something else; it is because the brain contains information that describes us having it. Moreover, given the limitations on the brain’s ability to model anything in perfect detail, one must accept that the consciousness we intuit and think and say we have is going to be different from the consciousness that we actually have. . . . I will make the strong claim here that this statement – the consciousness we think we have is different from, simpler than, and more schematic than, the consciousness we actually have – is necessarily correct. Any rational, scientific approach must accept that conclusion. The bane of consciousness theorizing is the naïve, mistaken conflation of what we actually have with what we think we have. The attention schema theory systematically unpacks the difference between what we actually have and what we think we have. In AST, we really do have a base reality to consciousness: we have attention – the ability to focus on external stimuli and on internal constructs, and by focusing, process information in depth and enable a coordinated reaction. We have an ability to grasp something with the power of our biological processor. Attention is physically real. It’s a real process in the brain, made out of the interactions of billions of neurons. The brain not only uses attention, but also constructs information about attention – a model of attention. The central hypothesis of AST is that, by the time that information about attention reaches the output end of the pathway ... , we’re claim-ing to have a semi-magical essence inside of us – conscious awareness. The brain describes attention as a semi-magical essence because the mechanistic details of attention have been stripped out of the description.

These are simply opinions of a hidden underlying information structure, confusing conscious experience itself with the recursive attention structures that any realistic description has to entail to bring physical brain processing into any kind

of concordance with environmental reality. His inability to distinguish organismic consciousness from AI is evidenced in Graziano (2017) where he sets out AST as a basis for biologically realisable artificial intelligence systems.

The answer to this apparent paradox that leaves our confidence in our conscious volition in tatters, is that the two processes, neural net attention schemes and subjective consciousness have both been selected by evolution to ensure survival of the organism from existential threats and they have done so as complementary processes. Organismic brains evolved from the excitable sentience of single-celled eucaryotes and their social signalling molecules that became our neurotransmitters a billion years after these same single-celled eucaryotes had to solve just these problems of growth and survival in the open environment. Brains are thus built as an intimately coupled society of eucaryote excitable cells communicating by both electrochemical and biochemical means via neurotransmitters, in such a way that the network process is an evolutionary elaboration of the underlying cellular process, both of which have been conserved by natural selection because both contribute to organismic survival by anticipating existential threats.

This is the only possible conclusion, because the presence of attention schemae does not require the manifestation of subjective consciousness to the conscious participant unless that too plays an integral role in survival of the organism. Indeed an artificial neural net with recursive schemes would do just that and have no consciousness implied, as it would be superfluous to energy demands unless it had selective advantage.

An adjunct notion is the ALARM theory (Newen & Montemayor 2023), we need to distinguish two levels of consciousness, namely basic arousal and general alertness. Basic arousal functions as a specific alarm system, keeping a biological organism alive under sudden intense threats, and general alertness enables flexible learning and behavioural strategies. This two-level theory of consciousness helps us to account for recent discoveries of subcortical brain activities with a central role of thalamic processes, and observations of differences in the behavioural repertoire of non-human animals indicating two types of conscious experiences. The researchers claim this enables them to unify the neural evidence for the relevance of sub-cortical processes, and of cortico-cortical loops, on the other, and to clarify the evolutionary and actual functional role of conscious experiences.

They derive evidence primarily from two animal studies. In Afrasiabi et al. (2021) macaques were anaesthetised, and the researchers stimulated the central lateral thalamus. The stimulation acted as a switch to trigger consciousness. However, it only prompted fundamental arousal because the macaques could feel pain, see things, and react to them, but they were unable, unlike regular wakefulness, to participate in learning tasks. A second experiment, Nakajima et al. (2019), provides evidence mice possess general wakefulness in their daily lives. The animals were trained to respond to a sound differently than to a light signal. They were also capable of interpreting a third signal that indicated whether they should focus on the sound or the light signal. Given that the mice learned this quickly, it is clear that they have acquired learning with focused conscious attention and, therefore, possess general vigilance.

In "Homo Prospectus" (Seligman et al. 2016), which asserts that the unrivalled human ability to be guided by imagining alternatives stretching into the future – "prospection" – uniquely describes *Homo sapiens*, addresses the question of how ordinary conscious experience might relate to the prospective processes that are neglected by psychology's 120-year obsession with memory (the past) and perception (the present) and its absence of serious work on such constructs as expectation, anticipation, and will. Peter Railton cites:

Intuition: *The moment-to-moment guidance of thought and action is typically intuitive rather than deliberative. Intuitions often come unbidden, and we can seldom explain just where they came from or what their basis might be. They seem to come prior to judgment, and although they often inform judgment, they can also stubbornly refuse to line up with our considered opinions.*

Affect: *According to the prosppection hypothesis, our emotional or affective system is constantly active because we are constantly in the business of evaluating alternatives and selecting among them.*

Information: *A system of prospective guidance is information-intensive, calling for individuals to attend to many variables and to update their values continuously in response to experience.*

They also see deliberative cognitive processes as intertwined with and integrated by intuitive processes:

One view, which we call the separate processors view, says intuition and deliberation are separate, distinct modes of thought. An opposing view says intuition and deliberation are thoroughly intertwined; deliberation is constructed with intuition as a main ingredient. On this second view, there aren't two independent processors. Rather, deliberation depends fundamentally on intuitive affective evaluations.

They associate imagination with the wandering mind, which we shall see is identifiable with the default mode network critical in ego dissolution and central to rehearsing survival strategies:

Think about what goes consciously through your mind during idle moments. This is mind-wandering, and it is deeply puzzling to theorists. The biggest puzzle is why we do so much of it. One study, which used experience sampling methods with 2,250 adults, found mind-wandering occurred in a remarkable 46.9% of the time points sampled.

On free will, the authors dodge the core philosophical debate, assuming that philosophers of all bents do embrace a form of free will, but instead pragmatically introduce the multiple-options question that plagues all environmental survival decisions:

We will argue that the distinctive mark of human freedom is latitude. Latitude refers to what agents have when the “size” of their option set is large. For now, we can say an agent has more latitude when the number of distinct options in the option set is larger. A bit later, we will provide a more refined account of how to understand the “size” of an option set.

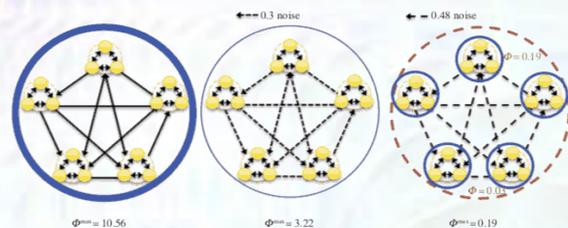

Some anticipatory aspects of our conscious experience of the world make it possible for the brain to sometimes construct a present that has never actually occurred. In the “flash-lag” illusion, a screen displays a rotating disc with an arrow on it, pointing outwards. Next to the disc is a spot of light that is programmed to flash at the exact moment the spinning arrow passes it. Instead, to our experience, the flash lags behind, apparently occurring after the arrow has passed (Westerhoff 2013). One explanation is that our brain extrapolates into the future, making up for visual processing time by predicting where the arrow will be, however, rather than extrapolating into the future, our brain is actually interpolating events in the past, assembling a story of what happened retrospectively, as was shown by a subtle variant of the illusion (Eagleman and Sejnowski 2000).

Given the complementary roles of conscious quantum measurement and edge-of-chaos coherence dynamics, far from being an ephemeral state of a biological organism’s brain dynamics that is irrelevant to the universe at large, the symbiotic cosmology asserts that consciousness has a foundational role in existential cosmology, complementary to the entire phenomenon of the physical universe. The conscious brain may also literally be a/the most complex functional system in the universe, so manifests emergent properties undeveloped in other physical processes. This is not dualistic, but an extension of quantum wave-particle complementarity to a larger complementarity, in which mind is complementary to the universe as a whole. It is thus non-local in a more complete way than the quantum wave aspect is in complementation to the localised particle aspect.

Hopeful Monster 3: Consciousness as Integrated Information

Fig 92: variations in recursive connectivity result in varying Φ .

Tononi and Koch’s (2015, Tononi et al. 2016) integrated information theory IIT, suggests a similar classification to the dynamical classification in the cosmology, running through states of limited human consciousness such as ketamine anaesthesia down to cephalopods and then Siri, thus invoking AI as putatively conscious if it has the right integrative algorithms. IIT constructs its model by starting from experience itself, establishing its classification via five phenomenological axioms: intrinsic existence, composition, information, integration and exclusion. It predicts that consciousness is graded, is common among biological organisms and can occur in some very simple systems. It will thus discount purely computational AI systems as non-conscious and makes a similar set of distinctions to those in the symbiotic cosmology. However, despite being based on characteristics of conscious behaviour, IIT becomes an abstract study of discrete probabilistic Markov systems, rather than subjectivity itself.

However the ground of the theory is probabilistic information, as indicated by its axiomatic definitions: **Mechanism** – Any subset of elements within a system that has cause–effect power on it (that is, that constrains its cause–effect space). **Cause–effect repertoire** – The probability distribution of potential past and future states of a system that is specified by a mechanism in its current state. **Cause–effect space** – A space with each axis representing the probability of each possible past and future state of a system. **Cause–effect structure** – The set of cause–effect repertoires specified by all the mechanisms of a system in its current state. **Integrated information (Φ)**: Information that is specified by a system that is irreducible to that specified by its parts. It is calculated as the distance between the

conceptual structure specified by the intact system and that specified by its minimum information partition.

Fig 92b: IIT sets out five axioms attempting to produce the principles of how an informational system needs to operate to model what we know of organismic conscious experience.

This does make a structural analysis consistent with prominent features of conscious experience as an integrated phenomenon. It is tolerant for example of octopus consciousness. However its analysis is based on abstract causal systems which are required to be composed of hierarchies of interacting subsets in a cause-effect repertoire.

This effectively creates the same combinations problem associated with attempts to structure panpsychism in the abstract form of Markov systems. This makes such abstract systems subject to the same criticism that the hard problem has with all objective descriptions being categorically incapable of subjectivity.

Chris Koch (2014) in *Scientific American*, introduces IIT as a form of panpsychism that spans the spread of animal kingdom:

All species—bees, octopuses, ravens, crows, magpies, parrots, tuna, mice, whales, dogs, cats and monkeys—are capable of sophisticated, learned, nonstereotyped behaviors that would be associated with consciousness if a human were to carry out such actions. For instance, bees are capable of recognizing specific faces from photographs, can communicate the location and quality of food sources to their sisters via the waggle dance, and can navigate complex mazes with the help of cues they store in short-term memory (for instance, “after arriving at a fork, take the exit marked by the color at the entrance”). Bees can fly several kilometers and return to their hive, a remarkable navigational performance. And a scent blown into the hive can trigger a return to the site where the bees previously encountered this odor. ... Given the lack of a clear and compelling Rubicon separating simple from complex animals and simple from complex behaviors, the belief that only humans are capable of experiencing anything consciously seems preposterous. A much more reasonable assumption is that until proved otherwise, many, if not all, multicellular organisms experience pain and pleasure and can see and hear the sights and sounds of life.

He notes that Darwin himself inquired into the mental powers of earthworms:

None other than Charles Darwin, in the last book he published, in the year preceding his death, set out to learn how far earthworms “acted consciously and how much mental power they displayed.” Studying their feeding and sexual behaviors for several decades—Darwin was after all a naturalist with uncanny powers of observation—he concluded that there was no absolute threshold between lower and higher animals, including humans, that assigned higher mental powers to one but not to the other.

As we also know from Smith (1978), that Darwin took this even further to the coelenterates and all animals:

*“To see a puppy playing [one] cannot doubt that they have free-will”
and if “all animals, then an oyster has and a polype.” (Darwin)*

He concedes that the explanatory gap between subjective consciousness and the physical world description cannot be simply bridged by complexity:

Yet the mental is too radically different for it to arise gradually from the physical. This emergence of subjective feelings from physical stuff appears inconceivable and is at odds with a basic precept of physical thinking, the Ur-conservation law—ex nihilo nihil fit. So if there is nothing there in the first place, adding a little bit more won't make something. If a small brain won't be able to feel pain, why should a large brain be able to feel the god-awfulness of a throbbing toothache? Why should adding some neurons give rise to this ineffable feeling? The phenomenal hails from a kingdom other than the physical and is subject to different laws. I see no way for the divide between unconscious and conscious states to be bridged by bigger brains or more complex neurons. ... A more principled

Intrinsic existence: Consciousness exists intrinsically: each experience is real, and it exists from its own intrinsic perspective, independent of external observers (it is intrinsically real) to account for experience, a system of mechanisms 0.5 in a state must exist intrinsically. To exist, it must have cause-effect power: to exist from its own intrinsic perspective, independent of extrinsic factors, it must have cause-effect power upon itself: its present mechanisms and state must 'make a difference' to the probability of some past and future state of the system (its cause-effect space).

Composition: Consciousness is structured: each experience is composed of phenomenological distinctions, elementary or higher-order, which exist within it the system must be structured: subsets of system elements (composed in various combinations) must have cause-effect power upon the system.

Information: Consciousness is specific: each experience is the particular way it is (it is composed of a specific set of specific phenomenological distinctions), thereby differing from other possible experiences (differentiation) the system must specify a cause-effect structure that is the particular way it is: a specific set of specific cause-effect repertoires — thereby differing in its specific way from other possible structures (differentiation). A cause-effect repertoire specifies the probability of all possible causes and effects of a mechanism in a state. A cause-effect structure is the set of cause-effect repertoires specified by all subsets of system elements and expresses how the system gives an actual form to the space of possibilities.

Integration: Consciousness is unified: each experience is irreducible to non-interdependent subsets of phenomenal distinctions the cause-effect structure specified by the system must be unified: it must be intrinsically irreducible to that specified by non-interdependent sub-systems ($\Phi > 0$) across its weakest (unidirectional) link:
MIP = minimum information partition.

Exclusion: Consciousness is definite, in content and spatio-temporal grain: each experience has the set of phenomenal distinctions it has, not less or more, and flows at the speed it does, not faster or slower the cause-effect structure specified by the system must be definite: specified over a single set of elements — not less or more — and spatio-temporal grains—not faster or slower: this is a cause-effect structure that is maximally irreducible intrinsically (Fmax), called conceptual structure, made of maximally irreducible cause-effect repertoires (concepts).

solution is to assume that consciousness is a basic feature of certain types of so-called complex systems (defined in some universal, mathematical manner).

He then leaps to panpsychism, as a philosophical viewpoint consistent with these perspectives:

Panpsychism is an elegant explanation for the most basic of all brute facts I encounter every morning on awakening: there is subjective experience. Tononi's theory offers a scientific, constructive, predictive and mathematically precise form of panpsychism for the 21st century. It is a gigantic step in the final resolution of the ancient mind-body problem.

But he then makes a broad critique of panpsychism's known deficiencies:

Yet, as traditionally conceived, panpsychism suffers from two major flaws. One is known as the problem of aggregates. Philosopher John Searle of the University of California, Berkeley, expressed it recently: "Consciousness cannot spread over the universe like a thin veneer of jam; there has to be a point where my consciousness ends and yours begins." Indeed, if consciousness is everywhere, why should it not animate the iPhone, the Internet or the United States of America? Furthermore, panpsychism does not explain why a healthy brain is conscious, whereas the same brain, placed inside a blender and reduced to goo, would not be. That is, it does not explain how aggregates combine to produce specific conscious experience.

He then uses panpsychism to launch a justification of Integrated Information Systems as a theory:

These century-old arguments bring me to the conceptual framework of the integrated information theory (IIT) of psychiatrist and neuroscientist Giulio Tononi of the University of Wisconsin–Madison. It postulates that conscious experience is a fundamental aspect of reality and is identical to a particular type of information—integrated information. Consciousness depends on a physical substrate but is not reducible to it. That is, my experience of seeing an aquamarine blue is inexorably linked to my brain but is different from my brain.

However, in a detailed review comparing the GNW and IIT theories, Maillé & Lynn (2020) in "Reconciling Current Theories of Consciousness" conclude that GNW concurs more closely with the empirical evidence:

Proponents of IIT point to its explanatory power: for instance, it can explain why the cortex is capable of producing conscious experience while the cerebellum is not, even though the cerebellum possesses up to four times more neurons. While the IIT has not received unambiguous validation (possibly due to the abstract nature of its description of consciousness, it provides one of the most detailed accounts for the emergence of conscious experience from an information-processing network.

The GNW theory (Dehaene and Changeux, 2011), in contrast to the IIT, was empirically derived from EEG and imaging studies in humans and primates. These studies have shown that when a stimulus is presented but not consciously perceived, activation can be seen mainly in the associated primary sensory cortices. When the stimulus is consciously perceived, however, activation in primary cortical areas is followed by a delayed "neural ignition" in which a sustained wave of activity propagates across pre-frontal and parietal association cortices. According to the GNW model, this allows relevant information to be broadcast across the brain to other subsystems for use in decision-making, reporting, memory consolidation, and other processes.

Unfortunately, while both IIT and GNW have obtained experimental support, testable predictions from both theories are seldom compared within the same dataset. In a recent issue of The Journal of Neuroscience, Noel et al. (2019) leveraged a previously published experimental data-set to directly compare IIT and GNW at the single-unit level.

Noel et al. (2019) did not find large enough pools of integrative and convergent neurons in vPM to generate sufficient statistical power, so this analysis was restricted to S1 neurons. The authors reasoned that if integrative neurons underlie conscious perception, then their multisensory representations should more closely track the state of consciousness than those of convergent neurons. Contrary to this, 69% of convergent neurons but only 37.1% of integrative neurons changed their multisensory response classification after propofol administration. Noel et al. (2019) additionally considered single-neuron physiological properties, including Lempel–Ziv complexity (a measure of the statistical complexity of stimulus-driven responses) and noise correlations (the amount of shared response variability between neurons). They found that both of these measures were less correlated with consciousness state in integrative neurons than in convergent neurons. Together, these findings argue against the IIT theory of consciousness.

Yaden et al. (2021) point out some of the problems with this kind of model in the context of psychedelics: "Although it would be interesting to investigate how psychedelic states relate to Φ , it is not clear how this would improve our understanding of the hard problem of consciousness." They note that relatively simple digital logic gates (e.g., XOR gate), which intuitively seem non-conscious, can generate large amounts of Φ (Cerullo, 2015) stating "It is also not clear that the assertion of complexity itself being a measure of consciousness is tenable." This is a natural critique of the IIT model in that, despite being an attempt to reason in the subjective, its sole basis in stochastic information cannot solve the hard problem, although it receives some philosophical support (Fallon & Blackmon 2021).

Bayne and Carter (2018) also critique the model, in dealing with whether conscious states can be assigned levels, exemplified by the idea that psychedelics induce a "higher" state of consciousness. "Advocates of IIT are explicitly

committed to the unidimensional view of conscious states, for they equate a creature's conscious state with its level of consciousness, and degrees of consciousness, according to IIT, are in turn understood in terms of the amount of integrated information Φ . The considerations advanced in this paper raise questions about the plausibility of this view, for we have seen that global states cannot be ordered along a single dimension."

"The only dominant theory we have of consciousness says that it is associated with complexity — with a system's ability to act upon its own state and determine its own fate. Theory states that it could go down to very simple systems. In principle, some purely physical systems that are not biological or organic may also be conscious" (Chris Koch).

However the final knell came from Merker et al. (2022):

Giulio Tononi's integrated information theory (IIT) proposes explaining consciousness by directly identifying it with integrated information. We examine the construct validity of IIT's measure of consciousness, phi (Φ), by analyzing its formal properties, its relation to key aspects of consciousness, and its co-variation with relevant empirical circumstances. Our analysis shows that IIT's identification of consciousness with the causal efficacy with which differentiated networks accomplish global information transfer (which is what Φ in fact measures) is mistaken. This misidentification has the consequence of requiring the attribution of consciousness to a range of natural systems and artifacts that include, but are not limited to, large-scale electrical power grids, gene-regulation networks, some electronic circuit boards, and social networks. Instead of treating this consequence of the theory as a disconfirmation, IIT embraces it.

A more recent study (Cogitate Consortium et al. 2023) compared integrated information theory (IIT) against global network workspace theory (GNWT) and found the results didn't perfectly match either of the theories. This has since resulted in an open letter treating IIT, in particular as pseudoscience (Fleming et al. 2023, Lenharo 2023b, 2024), causing David Chalmers to with a bet against Christof Koch that the mechanism by which the brain's neurons produce consciousness would be discovered by 2023.

The latest version of the theory, IIT 4.0 (Albantakis et al 2023) incorporates improvements to its formalism. However, [Wikipedia](#) notes that, while the theory has already been applied to explain the level and contents of experience in certain situations, it remains in development and still requires further validation and testing in cases where the level and contents of experience are well known (e.g. in awake humans capable of reporting, being exposed to natural sensory stimuli). Despite significant interest, IIT remains controversial and has been widely criticised, including that it is unfalsifiable pseudoscience. Proponents counter that there is some experimental support for it, but the fundamental validity of some of the tests used is questioned by some critics.

Anil Seth while supportive of the theory, claiming "conscious experiences are highly informative and always integrated" and that "one thing that immediately follows is that you have a nice post hoc explanation for certain things we know about consciousness," also has fundamental caveats "the parts of IIT that I find less promising are where it claims that integrated information actually is consciousness — that there's an identity between the two.

On its new axiomatic basis, IIT 4.0 proceeds by considering whether experience—phenomenal existence—has some axiomatic or essential properties, properties that are immediate and irrefutably true of every conceivable experience. Drawing on introspection and reason, IIT identifies the following five:

Intrinsicity Experience is intrinsic: it exists for itself.

Information Experience is specific: it is the way it is.

Integration Experience is unitary: it is a whole, irreducible to separate experiences.

Exclusion Experience is definite: it is this whole.

Composition Experience is structured: it is composed of distinctions and the relations that bind them together, yielding a phenomenal structure.

Existence The substrate of consciousness must have cause–effect power: its units must take and make a difference.

The authors state that a scientific theory of consciousness should account for experience, which is subjective, in objective terms. Being conscious — having an experience — is understood to mean that "there is something it is like to be" something it is like to see a blue sky, hear the ocean roar, dream of a friend's face, imagine a melody flow, contemplate a choice, or reflect on the experience one is having.

IIT aims to account for phenomenal properties—the properties of experience—in physical terms. IIT's starting point is experience itself rather than its behavioral, functional, or neural correlates. Furthermore, in IIT "physical" is meant in a strictly operational sense — in terms of what can be observed and manipulated.

Building from this “zeroth” postulate, IIT formulates five axioms in terms of postulates of physical existence:

Intrinsicity The substrate of consciousness must have intrinsic cause–effect power: it must take and make a difference within itself.

Information The substrate of consciousness must have specific cause–effect power: it must select a specific cause–effect state. This state is the one with maximal intrinsic information (ii), a measure of the difference a system takes or makes over itself for a given cause state and effect state.

Integration The substrate of consciousness must have unitary cause–effect power: it must specify its cause–effect state as a whole set of units, irreducible to separate subsets of units.

Irreducibility is measured by integrated information (ϕ) over the substrate’s minimum partition.

Exclusion The substrate of consciousness must have definite cause–effect power: it must specify its cause–effect state as this set of units. This is the set of units that is maximally irreducible, as measured by maximum ϕ (ϕ^*). This set is called a maximal substrate, also known as complex.

Composition The substrate of consciousness must have structured cause–effect power: subsets of its units must specify cause–effect states over subsets of units (distinctions) that can overlap with one another (relations), yielding a cause–effect structure or Φ -structure (“Phi-structure”).

Having determined the necessary and sufficient conditions for a substrate to support consciousness, IIT proposes an **explanatory identity**: every property of an experience is accounted for in full by the physical properties of the Φ -structure unfolded from a maximal substrate (a complex) in its current state, with no further or “ad hoc” ingredients.

Immediate criticisms at the axiomatic level render this analysis invalid right from the zeroth postulate, which asserts a priori that “a scientific theory of consciousness should account for experience, which is subjective, in objective terms”, remaining intentionally blind to the nature of subjectivity or its extreme category inconsistency with physicality.

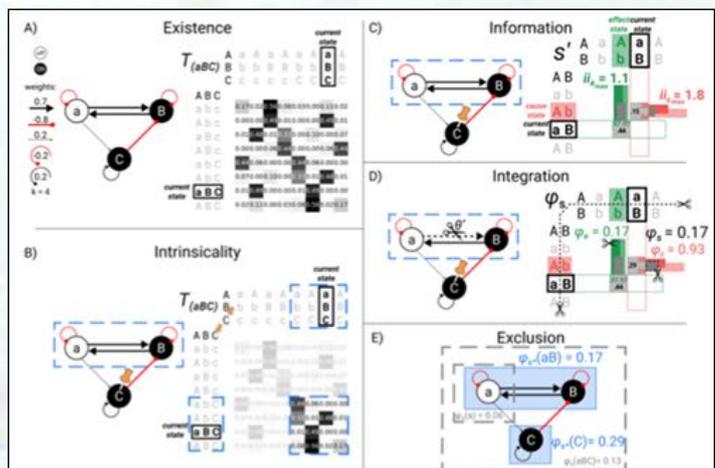

The attempts to paraphrase this by asserting that subjectivity expressed as being conscious is “what it is like to be” something is merely to have a physical structure representing it not to have the subjective experience at all. This is a purely functionalist view of consciousness in the sense of “conscious of” and it misrepresents subsequent axioms. Saying experience is “intrinsic” simply means “exists for itself” any autonomous physical process such as a wave on water satisfies this. The fact this it is specifically “the way it is” becomes “information in a tautologous self definition.

We then enter into further confining assumptions. Experience is claimed to be structured in the same way objective processes such as machines claiming “it is composed of distinctions and the relations that bind them together” but this does not mean they yield a “phenomenal” structure subjectively experienced.

The last, **existence** is revealing. The substrate of consciousness must have cause – effect power: its units must take and make a difference. What “taking” a difference is anyone’s guess, but making a difference is having conscious efficacy over the physical world e.g. in intentional behaviour. This confines any such theory to be either pure physicalism, or to be a subjective-objective interactionist theory like Symbiotic Existential Cosmology is.

IIT thus aims to account for phenomenal properties — the properties of experience — in purely physical terms. IIT’s starting point is experience, but its endpoint is axiomatically physical by identification. In IIT “physical” is meant in a strictly operational sense — in terms of what can be observed and manipulated. Thus abstract mathematical reality probability and information as well is identified with physicality, unilaterally assigning the abstract realm to physics.

Fig 92c: Identifying substrates of consciousness through the postulates of existence, intrinsicity, information, integration, and exclusion.

To seal the fate of the entire exercise, the substrate axioms execute the same series of

definitions determining without any escape, that the subjective aspect is now locked by equivalence to the physical. All of the substrate axioms repeat the mantra that each has cause–effect power, except for irreducibility which directly asserts that it “measured by integrated information (Φ)” giving integrated information a priori status. Thus the entire statement of IIT is simply a single axiom “subjectivity is physical”, not a consciousness theory at all.

This becomes finally apparent in the critical step – the **explanatory identity** – every property of an experience is accounted for in full by the physical properties of the Φ -structure unfolded from a maximal substrate (a complex) in its current state, with no further or “ad hoc” ingredients. In Anil Seth’s words “it claims that integrated information actually **IS** consciousness — that there’s an identity between the two”.

If this isn’t a bald statement of mind-brain identity theory, it is vacuous. There is no reference to Levine’s (1983) explanatory gap, Chalmers (1995) hard problem, or the fact that this is an attempt to solve the hard problem by solving a host of functional easy problems but simply stating IIT as an axiom, so that if systems design satisfy the substrate axioms as it is designed to do, then axiomatically, “my dear Watson”, it has unravelled subjective consciousness.

Emergence of Organismic Subjective Experience in the Cambrian

The foundation of consciousness arises not from the cortex, but from the ascending reticular activating system or ARAS (a), a collection of up to 50 separate brain stem ganglia giving the brain both its resonant excitations and modes of conscious activity from waking through deep and dreaming sleep and promote organismic survival through goal seeking affects ensuring survival. The ARAS, fig 92(d) is fast composed of several neural circuits connecting the dorsal part of the posterior midbrain and anterior pons to the cerebral cortex via distinct pathways that project through the thalamus and hypothalamus. Consciousness is thus supported by the most “drug-addled” foundation that also goes back in evolutionary terms to our single-celled eucaryote ancestors.

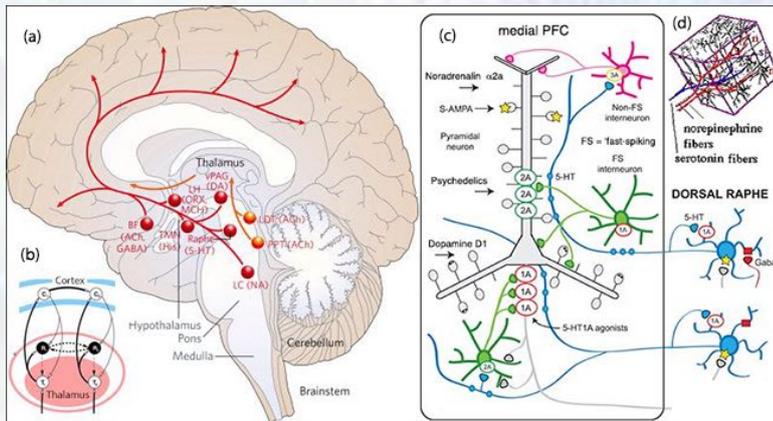

Fig 92d: Key components of the ascending arousal system.

The thalamic pathway (orange) consists primarily of cholinergic acetyl-choline neurons (aCh) in the pedunculopontine (PPT) and laterodorsal tegmental nuclei (LDT), which excite the thalamo-cortical-thalamic electrical and glutaminergic resonances (b) accompanying consciousness (Shepherd & Yamawaki 2021).

The hypothalamic pathway (red) is composed primarily of neurons that release adrenergic monoamine neurotransmitter modulators, dopamine (DA), norepinephrine (NA), serotonin (5HT), and histamine (His). These send neuromodulatory projections to the cortex - especially the prefrontal cortex. These arise from neurons in the monoaminergic cell groups, including the tubero-mammillary nucleus (TMN) containing histamine (His), the substantia nigra (A9) and the ventral tegmental area (A10) group containing dopamine (DA), the dorsal and median Raphe nuclei containing serotonin (5-HT), and the Locus coeruleus (LC) containing noradrenaline (NA). Dopamine is associated with motivation and fulfilment and can indirect dopamine effects from stimulants such as amphetamines can also cause sleep delay, serotonin with mood and survival oriented modulation and alleviating depression and inducing psychedelic states, nor-adrenaline with vigilance and histidine with wakefulness.

The dopamine, nor-epinephrine and serotonin ascending pathways spread across the cortex (a, d) with dopamine in particular concentrated in the prefrontal region. They enter different layers of the cortex, as can be seen in (d) (NA and 5HT only) and in (c), where the positions of serotonin (1a) and (2a), nor-adrenaline (α 2a) and dopamine (D1) receptors are shown on different parts of the pyramidal neuron. This pattern is largely repeated across the entire micro-columnar structure of the cortex. As shown in (c), the serotonin receptors are served by ascending fibres from the Raphe nuclei, so the global mode of serotonin modulation, in the absence of psychoactive molecules, is driven from the basal brain. Orexin (ORX) neurons of the lateral hypothalamus, opposed by melanin concentrating hormone (MCH), act as a flip-flop between sleep and wakefulness, driven by ascending reticular pathways of aCh, his, 5HT and

NA. The ORX innervate every component of the ascending reticular activating system and coordinate activity within the entire system. The failure of these leads to narcolepsy through loss of coordination of the sleep-wakefulness cycle.

Receptors for the very same molecules in the ARAS are pivotal in the span of key psychoactive drugs (fig 41), from antipsychotics, which are like an elephant sitting on the entire receptor keyboard, as broad-spectrum antagonists, with multiple negative and damaging side effects, including sometimes irreversible disabilities such as tardive dyskinesia and increased overall mortality, through tricyclic antihistamines and antidepressants which have similar indiscriminate activity, to more recent SSRI and SNRI antidepressants which are less harmful but still cause psychological dependence in long-term use. By contrast psychedelics are focused on serotonin super-agonism of the 5HT_{2a} and 5HT_{2c} receptors with mild agonism of dopamine and nor-adrenaline receptors adding rewarding but also a degree of anxiogenic features. The 5HT_{2a} receptors are centrally involved in psychedelic states, while the 5HT_{2c} receptors promote anxiety and relieve depression.

Psychedelic super-agonism is a paradoxical effect which sets off a different metabotropic pathway from serotonin itself, which modulates associated glutamate mGluR2 receptor expression, resulting in increased neurodynamic linkages between brain regions crossing sensory and other regions and increasing signal complexity and decoherence. MDMA has the effect of causing the serotonin (SERT) reuptake transporter to reverse, dumping large amounts of serotonin in the synaptic cleft, resulting in its title “ecstasy”, but is also liable to cause oxidative damage because of its methylenedioxy molecular structure.

The most rostral neurons in the brain with a major role in sleep control are γ -aminobutyric acid cells located in the basal forebrain and in the anterior hypothalamus (GABA in a). These GABAergic cells are unique: while most neurons tend to have minimal activity during non-rapid eye movement (NREM) sleep, these cells are more active during NREM sleep than they are in rapid eye movement (REM) dreaming sleep or in waking. They also increase discharge rates with sleep onset and continue to release GABA at a high level while sleep continues. Serotonin, histamine, and norepinephrine cells are normally silent during REM sleep and active in waking. GABA applied to the serotonin and norepinephrine cell groups triggers REM sleep. Acetylcholine is at its strongest both during REM sleep and awake. The orexin neurons of the lateral hypothalamus innervate every component of the ascending reticular activating system and coordinate activity within the entire system. Their failure leads to narcolepsy through loss of coordination of the sleep-wakefulness cycle. Dopamine also appears to have involvement in the sleep wakefulness cycle.

Complementing the ascending cholinergic reticular activating system evoking the energetic resonances between the thalamic nuclei and the cerebral cortex we associate with active consciousness is the envelope of the cerebral cortex, which, with the exception of prefrontal areas involved in attention, is organised as an experiential filter on ascendent activity, in six cortical layers, distributed across the cortex in micro-columns, which despite the variations of visual, auditory and somato-sensory processing, all have a common architecture and physiology. This cortical experiential filter under normal operation eliminates the subterranean level of processing to form a perceptual internal model of reality spanning all dimensions of subjective experience external and internal. This means that we don't see the physical world of wave particles directly as it is, but an inner representation of it, e.g. through three colour vision based on the versions of rhodopsin in the cones of the retina, augmented by higher level visual processing areas into veridical 3D vision, symphonic spectral audition, alluring olfaction of hundreds of receptor dimensions and subtle tactile through to emotional and internal organismic sensations. Because some areas of the cortex include information about self and other, these also include recursive experiences of autonomous agency over the world around us, distinct from consciousness itself. As well, partly through culture and language, we have developed higher processes of cognition, analytical thought and reason, extending from natural intuition of the environment around us and our

relationships with other agents. This internal model of reality, although located biologically in the brain becomes the holy grail of subjective experience, as a kind of controlled hallucination, we call subjective conscious experience.

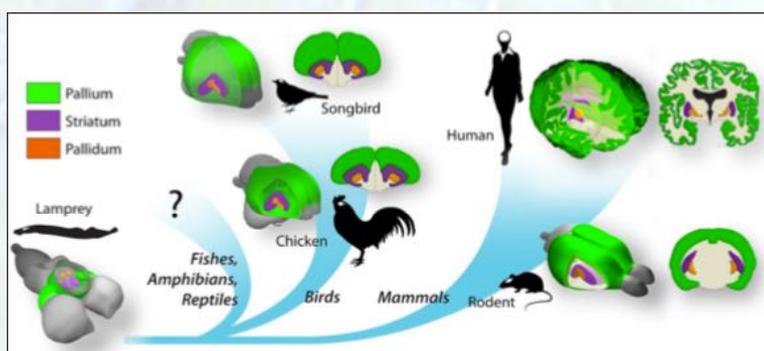

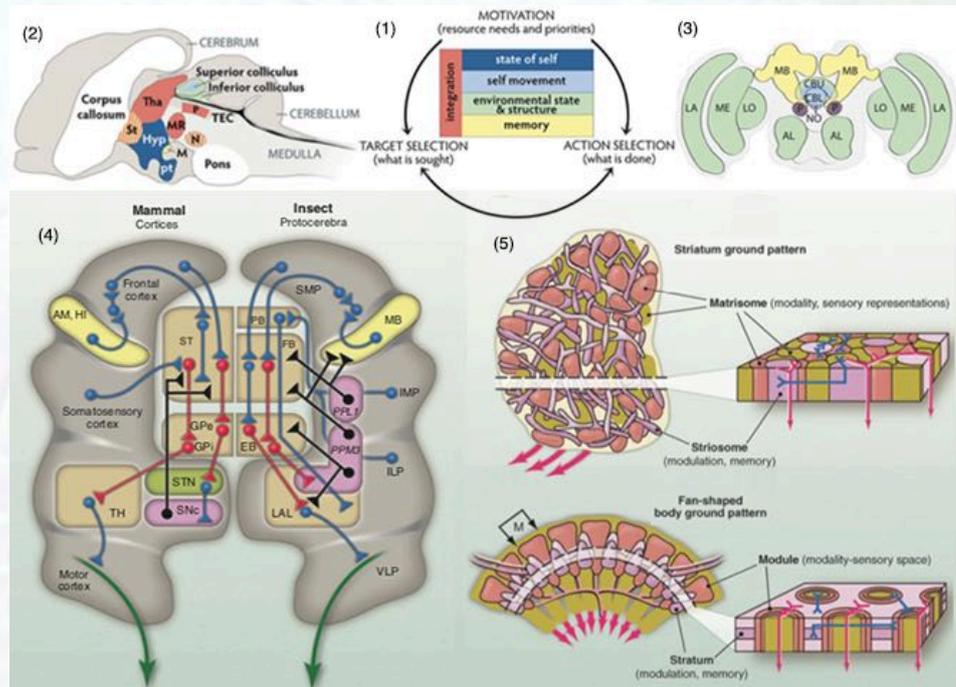

Fig 92e: The parallel development of the pallium, striatum and pallidum in vertebrates (Boraud, Leblois & Rougier 2018). In birds neuronal density in the pallium is twice as high as mammals and equivalent to primates (Olkowicz et al. (2016).

We have also noted the cyclic interaction of the cortex with the thalamus and basal ganglia (striatum, pallidum) in [fig 83](#). This has been cited (Boraud, Leblois & Rougier 2018) as the basis for parallel evolutionary relationships running all the way from stem vertebrates such as the lamprey through to both birds and mammals as climax intelligence.

Barron & Klein (2016) in a carefully researched analysis, propose that insects, and by extension arthropods, have the capacity for subjective experience, the core feature of consciousness. In vertebrates the capacity for subjective experience is supported by integrated structures in the midbrain that create a neural simulation of the state of the mobile animal in space. This integrated, egocentric representation of the world from the animal's perspective is sufficient for subjective experience. Structures in the insect brain perform analogous functions, implying the insect brain also supports the capacity for subjective experience. In both vertebrates and insects, this form of behavioral control system evolved as an efficient solution to basic problems of sensory reafference (resolving the confusing sensory input caused by self-motion) and true navigation. The brain structures that support subjective experience in vertebrates and insects are very different from each other, but in both cases, they are basal to each clade. The origins of subjective experience can thus be traced at least as far back as the Cambrian.

Fig 93: (1) Decision making involves an assessment of what is needed and where and how the needed resources can be obtained. Decision making can therefore be considered to involve three domains: internal motivations, target selection, and action selection. (2) Structures of the vertebrate midbrain (not to scale) supporting the behavioural "core control system." The vertebrate midbrain supports an integrated multisensory model of the state of the animal in space, which supports effective decision making. (3) The structures of the insect brain create an integrated neural model of the state of the insect in space that is functionally analogous to that described for the vertebrate brain. (4)

Corresponding regions of the basal ganglia (left) and insect central complex (right) and their associated regions are aligned, as are their relevant connections. Inhibitory pathways are shown in red, dopaminergic pathways in black, and other pathways (excitatory or modulatory) in blue. (5) The mammalian striatum consists of two principal subunits. Striosomes within the matrix of the striatum [in mauve, purple] are associated with discrete volumes of the striatal matrix, called matrisomes [brown, yellow]. In mammals, striosomes receive inputs from the hippocampus and amygdala via the frontal cortex, among other brain regions, carrying information about internal physiological states (modulations, memories). Matrisomes are supplied by cortical representations of sensory space and sensory modalities. Interactions and associations among matrisomes, and between matrisomes and striosomes, are mediated by local interneurons (blue) that integrate and provide information to striatal afferents supplying direct and indirect GABAergic pathways (red arrows) to the globus pallidus and subthalamic nucleus. The insect fan-shaped body from *Mantis religiosa*, labeled with antisera against allatostatin (green) and β -tubulin (ochre)] consists of two principal subunits: tangential stratifications (schematized in mauve, purple) that intersect columnar modules (yellow, brown).

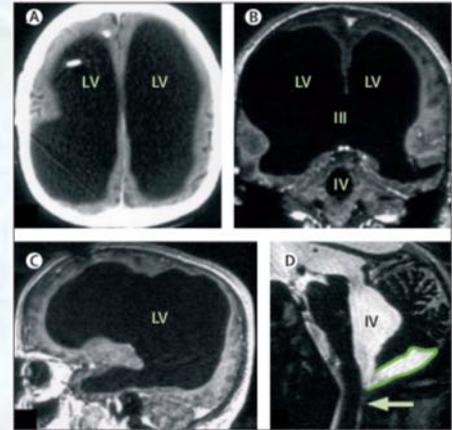

Strausfeld & Hirth (2013) have, in a more focussed study, also shown that the arthropod central complex and vertebrate basal ganglia derive from comparable embryonic basal forebrain lineages that are specified by an evolutionarily conserved genetic program leading to interconnected neuropils and nuclei that populate the midline of the forebrain-midbrain boundary region. In the substructures of both the central complex and basal ganglia, network connectivity and neuronal activity mediate control mechanisms in which inhibitory (GABAergic) and modulatory (dopaminergic) circuits facilitate the regulation and release of adaptive behaviors (Graybiel & Matsushima 2023). Both basal ganglia dysfunction in vertebrates and central complex dysfunction in arthropods result in behavioral defects, including motor abnormalities, impaired memory formation, attention deficits, affective disorders, and sleep disturbances. The observed multitude of similarities suggests deep homology of arthropod central complex and

vertebrate basal ganglia circuitries underlying the selection and maintenance of behavioral actions.

Fig 93b: A man with almost no cortical tissue with hydrocephalus who nevertheless was married with children and worked in the civil service (Feuillet et al. 2007).

An anatomical validation of the integral role of the brainstem in consciousness is provided by Bjorn Merker (2007):

The principal macrosystems of the vertebrate brain can be seen to form a centralized functional design in which an upper brain stem system organized for conscious function performs a penultimate step in action control. This upper brain stem system retained a key role throughout the evolutionary process by which an expanding forebrain – culminating in the cerebral cortex of mammals – came to serve as a medium for the elaboration of conscious contents. This highly conserved upper brainstem system, which extends from the roof of the midbrain to the basal diencephalon, integrates the massively parallel and distributed information capacity of the cerebral hemispheres into the limited-capacity, sequential mode of operation required for coherent behavior. It maintains special connective relations with cortical territories implicated in attentional and conscious functions, but is not rendered nonfunctional in the absence of cortical input. This helps explain the purposive, goal-directed behavior exhibited by mammals after experimental decortication, as well as the evidence that children born without a cortex are conscious. Taken together these circumstances suggest that brainstem mechanisms are integral to the constitution of the conscious state, and that an adequate account of neural mechanisms of conscious function cannot be confined to the thalamocortical complex alone.

Barron & Klein (2016) note:

There is now considerable evidence that, in humans, subjective experience can exist in the absence of self-reflexive consciousness, and that the two are supported by different neural structures. Midbrain structures, rather than cortex, seem to be especially important. Merker (2005, 2007), Parvisi and Damasio (2001), Damasio and Carvalho (2013), and Mashour and Alkire (2013) have argued that the integrated structures of the vertebrate midbrain are sufficient to support the capacity for subjective experience. Merker (2007) notes that subjective experience is remarkably sensitive to damage to midbrain structures. Conversely, there is evidence of preserved consciousness even in patients who lack a cortex (Merker 2005). Further, although cortical damage can have profound effects on the contents of consciousness, damage to any portion of the cortex alone can spare the basic capacity for subjective experience.

Merker suggests that an important function of the midbrain is to combine interoceptive (stimuli arising from within the body) and exteroceptive (stimuli external to the body) sensory information. Information on the environment, and the location and movement of the animal within it, is processed within the roof of the midbrain (the tectum, or colliculus in mammals). Information about homeostatic needs is processed within the floor of the midbrain (the hypothalamus and associated structures). Nuclei located between these poles integrate this information to produce a unified multimodal neural model of the spatial location of resources relative to the animal, which is coupled to, and weighted by, the extent to which different resources are needed by the animal. Vertebrates organize their behavior by reference to this integrated model of the environment rather than by reacting to independent sensory inputs.

The insects are an extremely diverse group, but all insect brains have a common anatomical plan. The nervous system contains an enlarged cephalic ganglion (a brain) specialized for sensory processing and integration. This is linked by paired ventral nerve cords to a series of smaller ganglia for the thoracic and abdominal body segments. The insect nervous system has frequently been stereotyped as decentralized, with the cephalic ganglion acting simply as a region of sensory input that triggers motor responses organized by the segmental ganglia. This interpretation is incorrect and outdated. The insect brain resolves action and target selection, processes sensory information, and clearly executes a command function over the behavioral system.

However they deny that more "primitive" organisms, show all the features they associate with organismic subjective experience, although this is purely on anatomical and behavioural grounds in a way which underestimates the capacity of even primitive hydra for "innovative" coordinated adaptive behaviours (fig 256):

The cubozoan box jellyfish Tripedalia cystophora shows dynamic behavior that includes actively hunting its prey. It has a well-developed geosense and visual sense thanks to 24 lensed eyes distributed around the body, yet the nervous system is entirely decentralized. Sense organs independently modulate activity in regions of the sensory net and muscle walls to steer the animal. The outcome of local sensory input acting on local muscle activity is an adaptive change in the swimming direction and speed of the animal, but the simple behavioral control system is entirely decentralized. Although such systems manifest the appearance of adaptive and dynamic targeting, they are nothing more than simple decentralized stimulus–response systems.

The nematode Caenorhabditis elegans possesses a famously simple and well-characterized centralized nervous system that can integrate input from an array of thermo-, mechano-, chemo-, and nociceptors, along with an interoceptive sense of time to organize directed movements. Sensory inputs are integrated at the level of an array of interneurons that compete for activation of the motor neurons. The simple nervous system of C. elegans can also support various forms of learning such as habituation and classical

associative conditioning, enabling adaptive change in behavior with experience. Nematodes are thus able to integrate multiple forms of sensory input using a centralized nervous system, but it seems that their behavior is organized as responses either to the immediate sensory environment or to immediate interoceptive signals of physiological state. Action selection in nematodes is driven by shifts in global brain dynamics, and there is sufficient plasticity in the nematode nervous system for their responses to vary with system state. However, there is no evidence that nematodes can actively hunt for things beyond their immediate sensory environment.

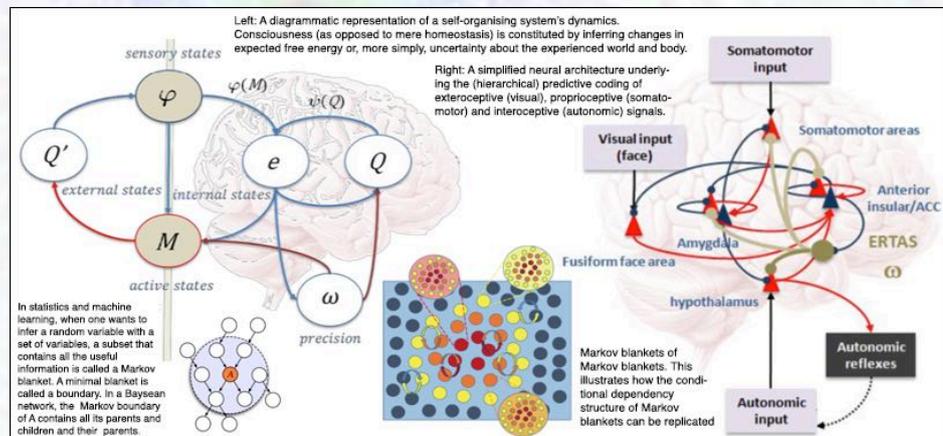

Hopeful Monster 4: Is Consciousness just Free Energy on Markov Landscapes?

Solms and Friston (2018) have proposed a model of consciousness, based on previous ideas of the mid-brain as a basis for consciousness, in which the brain acts as a prediction machine endeavouring to minimise the free energy difference between the actual state of the world and its predicted state. Friston (2010) is the architect of a major theory of brain function based on these ideas. Higher-level areas of the nervous system (i.e., higher-order cortical structures) generate top-down synaptic ‘predictions’ aimed at matching the expected bottom-up synaptic activity at lower-level areas, all the way down to ‘input’ activity at sense organs. Top-down signals encode a kind of ‘best guess’ about the most likely (hidden) causes of bodily sensations.

The model is again based on abstract stochastic processes. A Markov blanket (Kirchov et al. 2018) defines the boundaries of a system (e.g. a cell or a multi-cellular organism) in a statistical sense in a way that can be used to define homeostatic and adaptive processes and can be recursive as in a multicellular organism. It is a statistical partitioning of a system into internal states and external states, where the blanket itself consists of the states that separate the two, constituting a statistical boundary that sets something apart from that which it is not. This shows that internal and external states are conditionally independent, as they can only influence one another via active and sensory states. The states that constitute the Markov blanket can be further partitioned into active and sensory states.

They use both ‘subjective’ and ‘objective’ to refer to observational perspectives, so subjective is not really subjective, but internal observation. The subjective perspective “upon” the organism realises the “being” of the organism which they call ‘interoceptive’.

Fig 94: Solms-Friston model and Markov blankets. Predictive coding formulates free energy or surprise in terms of precision weighted prediction errors. A prediction error (e) here is the difference between a sensation (φ) produced by some action (M) and the sensation predicted by a generative model $\psi(Q)$. Here, Q stands for internal expectations about – or representations of – hidden external states and $\psi(Q)$ is the prediction of sensory inputs that would have been encountered given those

external states, under the generative model. Under some simplifying assumptions, we can now associate free energy (F) with the amount of prediction error weighted by its precision (ω). Precision corresponds to the reliability, or inverse variance, of sensory fluctuations (in various modalities) and is an important aspect of inference; namely, the *representation of uncertainty*.

The objective perspective realises the “body” of the organism they call ‘exteroceptive’. They take an admittedly metaphysical position that neither of these observable realisations can be explained away by the other, which is fine. In other words, data about an organism that is derived from both interoceptive and exteroceptive perspectives must be reducible to one and the same set of explanations. This places each in their own parallel causal train except that an assumption is made of an underlying unity from which these both derive:

The starting point of my argument raises an interesting philosophical question. If body and mind are two appearances (aspects) of the same underlying thing, then what stuff is the underlying thing made of? In other words, using the analogy of thunder and lightning, what is the metapsychological equivalent of “electricity” (i.e., the thing that gives rise to thunder and lightning, both)?

We come to the devastating abstract crunch – “*Therefore, biological explanations (as opposed to descriptions) are best formulated in neither interoceptive nor exteroceptive phenomenal terms, but rather as abstractions*”. This is converting the central complementarity of subjective consciousness and objective brain into other complementarities of a different sort interoceptive v exteroceptive observation or perception and ascending neural pathways v cortical connections, neither of which are consistent with the original and fundamental subject-object complementarity at the heart of cosmology.

Their central claim is that their combined insights invoking this entirely abstract stochastic process yields a straightforward response to Chalmers’ question “*why is there something it is like to be an organism, for the organism, and how does this something-it-is-like-ness come about?* “. These two insights are: (1) that the primary function of consciousness is not to register states of the external world but rather to register the internal states of the experiencing subject and (2) concerns minimal conditions – a fundamental property of living things (i.e., biological self-organising systems) is *their tendency to resist the second law of thermodynamics* and that this functional property emerges *naturally* within any ergodic random dynamical system that possesses a *Markov blanket*.

The first is not based in philosophy but on anatomical and physiological evidence, which suggests that consciousness is “quintessentially” interoceptive. Their argument goes as follows: conscious qualia arise primarily not from exteroceptive perception (i.e., vision, hearing, somatic sensation, taste and smell), and still less from reflective awareness of such representations, but rather from the endogenous arousal processes that activate them.

Exteroceptive representations are intrinsically unconscious – they do not inherently possess ‘something-it-is-like-ness’. They only acquire conscious quality when they are, in Chalmers’ words, “entertained” by the subject; i.e., when they are selectively activated by a more fundamental form of consciousness. In short, mental images can only be experienced by a conscious subject and they are in fact states of the conscious subject. The arousal processes that produce what is conventionally called ‘wakefulness’, in our view, therefore, constitute the experiencing subject – they are consciousness itself – explicitly the arousal functions of the centrencephalic structures that sustain wakefulness and behavioural responsivity which in turn supply the conscious character of some higher cortical functions. The latter perceptual and cognitive functions (which are otherwise typically unconscious) derive their consciousness absolutely from the centrencephalic region.

This is fine as a description of the relationship between ascending pathways such as the reticular activating system, and underscores the relationship between thalamic circuits as drivers of activity and cortical circuits as responsive constraints, however identifying consciousness itself with the ascending pathways is not accurate physiologically in terms of active CNS dynamics, as exemplified in the EEG, where we see cortical states active as a whole associated with conscious experiences, with the ascending pathways just providing as in their thermodynamic model a free-energy substrate.

In the Solms-Friston model, autonomous systems, including nervous systems are modelled in terms of predictive coding, which formulates free energy or surprise in terms of precision weighted prediction errors. They state specifically that the model although claiming to solve the hard problem is following the “*Helmholtz school of medicine, whose members swore an oath in 1842 to the effect that “no forces other than the common physical chemical ones are at work in the organism*”. In the model, precision corresponds to the reliability, or inverse variance, of sensory fluctuations and is an important aspect of inference in the representation of uncertainty. Precision is the confidence placed in the (predicted) consequences of an action or in a source of sensory evidence. In the ideal adaptive state of the organism – where negentropic demand is met by optimal predictions – Nirvana – there are no prediction errors and the expected free energy is absolutely minimised – homeostasis with no uncertainty or entropy and infinite precision. They claim this scheme, with recurrent exchanges of (ascending) prediction errors and (descending) predictions – closely resembles empirical message passing in cortical and subcortical hierarchies. In this context, action reduces to proprioceptive (motor) and interoceptive (autonomic) reflexes that are driven by descending predictions from the brain’s (hierarchical) generative model. Precision controls the influence of prediction errors on action and perception.

They then note that physiologically, precision is usually associated with the postsynaptic gain of cortical neuronal populations reporting prediction errors, associated – through free energy minimisation – with selective arousal or attentional selection. They then claim it is precisely this neuromodulatory synaptic mechanism that is targeted by psychotropic and psychedelic drugs on the basis of Nour and Carhart-Harris (2017).

The picture is actually much more complicated. Both psychedelics and other agents, from dissociatives to stimulants such as amphetamines, have differing and varied affects on attention. While psychedelics are associated with both a

drop in the default mode network and sensory overload from upwelling activity, this isn't easily analysed as simply prediction errors, nor an overall change in thermodynamic free energy minimisation. It is also manifestly inconsistent to associate surprise and uncertainty only with its suppression. Cultural expressions from music to scientific discoveries are all intimately associated with both uncertainty and surprise.

The approach of minimising surprise, while it does tally with avoidance of primary existential threats is not solved by homeostasis, but by self organised criticality at the edge of chaos, and there is no empirical basis to define neural processes as stochastic Bayesian networks per se. Hence like IIT, this model is analogical and not causal.

Solms (2019) makes his homeostatic direction explicitly clear, citing personal experience dealing with subjects who have severe hydrocephalus and little cortical tissue, although some with seemingly empty cortices have small regions of cortical tissue having far more intense activity than normal:

I first expressed the view in 1997 that the problem of consciousness will only be solved if we reduce its psychological and physiological manifestations to a single underlying abstraction. It took me many years to realize that this abstraction revolves around the dynamics of free energy and uncertainty. Free energy minimization is the basic function of homeostasis, a function that is performed by the same brainstem nuclei that I was led to infer – like others, on independent (clinico-anatomical) grounds – were centrally implicated in the generation of consciousness. In other words, the functions of homeostasis and consciousness are realized physiologically in the very same part of the brain. This insight led to the collaborative work that enabled Friston and me to expand the variational free energy formulation of the mechanism of homeostasis to explain the mainspring of consciousness itself.

This viewpoint focuses on feeling, which is then identified with consciousness as a whole:

The function of experience cannot be inferred from perception and memory, but it can be inferred from feeling. There is not necessarily "something it is like" to perceive and to learn, but who ever heard of an unconscious feeling—a feeling that you cannot feel?

This opens up a discussion of the fact that the reticular activating system coupled with the para-cortical limbic system circuiting through the amygdala, hippocampus and cingulate is the seat of consciousness as volitional affect (emotion):

Consciousness persists in the absence of cerebral cortex, as does volitional behaviour. As Damasio and Carvalho (2013) put it: Decorticated mammals exhibit a remarkable persistence of coherent, goal-oriented behavior that is consistent with feelings and consciousness. Consciousness is obliterated by focal lesions of the brainstem core – in a region conventionally described as the extended reticulothalamic activating system (ERTAS). ... If core brainstem consciousness is the primary type, then consciousness is fundamentally affective. The arousal processes that produce what is conventionally called "wakefulness" constitute the experiencing subject. In other words, the experiencing subject is constituted by affect. ... Although many cognitive scientists still must be weaned of the view that the cerebral cortex is the seat of consciousness the weight of evidence for the alternative view that the arousal processes generated in the upper brainstem and limbic system feel like something in and of themselves, is now overwhelming.

While these physiological details are important and correct, there are two critical flaws:

- (1) Although the cortex may be electro-dynamically passive on its own and the mid-brain may have strategically excitable properties consistent with intentional awareness, to claim consciousness is only root brain stem afferent activation trivialises its nature and complexity, when all the elaborate details of the conscious experiences we have are clearly derived through the modulation of the cortex under the active excitation of the thalamo-cortical loop.
- (2) David Chalmers' philosophical description of subjectivity, as a fully conscious intact human would experience it "feel like something in themselves" is a misconstruction. Chalmers is carefully stating what is is like to actually experience consciousness subjectively, not what observation of afferent pathways is associated with, in terms of anatomical dissection of function.

This equating of feeling with consciousness runs into all sorts of problems by disabling some key aspects of conscious experience in favour of others, not just in waking life but also in alternative mental states. Someone driving a car may or may not be centred on their feelings some of the time, or be experiencing intense emotions likely to cause an accident, but for most people, driving is a conscious sensory-motor experience. One of the most outstanding features of psychedelic visions is kaleidoscopic imagery, which one both experiences as real veridical perceptions "out there" and a suppression of egotistical emotions leading to quiescent feelings amid overwhelming perceptual, sounds, scenes and geometrical patterns, which the person intimately experiences as consciousness expansion. The same thing with dreaming states which are often profoundly visual and in which emotions may reach crisis point in perceived existential crises, but in no way is feeling as such 'felt' to be the sine qua non of conscious experience. There is also a fundamental basis to the notion that all forms of perception both sensory and somatosensory are part of the envelope of conscious experience as is volition and the perception of intent. To thus identify the raw free energy of reticular activation as consciousness itself is a severe mischaracterisation.

Solms notes that this view is not shared by a long history involving the NCC or neural correlate of consciousness:

This assignment that the NCC does not lie in the brain stem, continues to this day. Crick's closest collaborator, Christof Koch, says of the deep brainstem nuclei that "they are enablers [of consciousness] but not content-providers".

Markov blankets are then conflated with two central properties accompanying conscious volition – selfhood and intentionality:

Readers may have noticed already that the dynamics of a Markov blanket generate two fundamental properties of minds— namely (elemental forms of) selfhood and intentionality. It is true that these dynamics also generate elemental properties of bodies— namely an insulating membrane (the ectoderm of complex organisms, from which the neural plate derives) and adaptive behavior. This is a remarkable fact. It underpins dual-aspect monism.

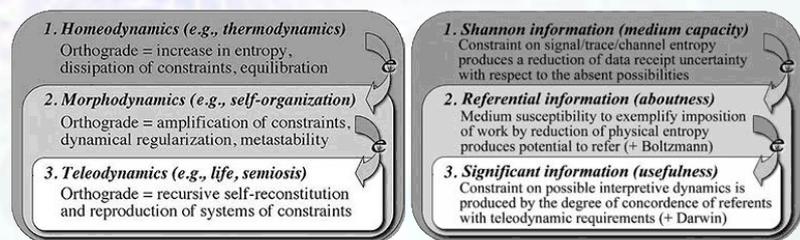

One can understand that selfhood and intentionality are fundamental properties of all autonomous life forms, from the first prokaryotes to *Homo sapiens*, but this doesn't mean they constitute experiential conscious volition as we know it, or that the neural plate substrates of early development define consciousness. However claiming that this stochastic description of (sensory) input and (motor) output solves the hard problem in terms of conscious volition is the most tissue thin analogy conceivable. The critical point remains that a pure abstract system is categorically inconsistent with actual subjectivity, just as objective physical processes are.

While the model, in viewing subjective conscious experiences as anticipatory top-down simulations attempting to minimise mismatch with bottom-up environmental boundary conditions, in a way which is consistent with the anticipatory role of consciousness in Symbiotic Existential Cosmology, and the notion of the brain as an environmental filter rather than a physically causal computer, the subjective aspect is reduced to abstract stochastic homeostasis.

Hopeful Monsters 5: Can Teleological Thermodynamics Solve the Hard Problem?

Terrence Deacon in "Incomplete Nature: How Mind Emerged from Matter" sets out a descriptive teleological thermodynamics, which is an extension of Ilya Prigogine's (1984) concept of far-from-equilibrium thermodynamics in a three-layered structure of homeo-, morpho- and teleo-dynamics. These three categories actually coincide with (1) inanimate matter, (2) far-from-equilibrium stability structures such as in chemical biogenesis, and (3) living organisms. We are already intimately familiar with each of these, so the description is simply a thermodynamic recasting, which is insightful, but not empirically demonstrated in any proof-of-principle examples.

Fig 95: Left Nested hierarchy of three emergent levels of dynamics and their emergence from subvenient physical processes. Right Three nested conceptions of information. Shannon information is the most minimal and the most basic. Referential information is emergent (e) from Shannon information, and significant—or useful—information is emergent from referential information.

We already know that biological systems consist of fractal layers of organisation arising from the symmetry-breaking of the quantum forces as a consequence of non-linear charge energetics to interactively produce: quarks, hadrons, atomic nuclei, atoms, molecules with increasingly fractal cooperative weak-bonding structures, supra-molecular complexes such as the ribosome, organelles such as the membrane and Golgi apparatus, cells, tissues, organs such as the brain organisms and the biosphere. Teleodynamic work is the production of contragrade teleodynamic processes, that work in opposition to the usual orthograde direction, that in homeo-dynamic systems leads to increasing entropy at equilibrium. An orthograde teleodynamic processes is an end-directed process that will tend to occur spontaneously. By contrast, contragrade change is described as the natural consequence of one orthograde process influencing a different orthograde process — for example, via some intervening medium. This implies that in one sense, all change ultimately originates from spontaneous thermodynamic processes controlled passively by constraints.

Yes biogenesis and biological evolution is teleologically directed towards diversity and yes evolution is a process by which adventitious mutation is sequestered in the genome and becomes available as significantly useful information

by natural and sexual selection. In this sense “Incomplete Nature” is a self-confessed description of biogenesis, evolution and the constraints on organismic development, rather than mind or consciousness and here it does have descriptive insightfulness. However it is subtly similar in its cognitive respect to Daniel Dennett's multiple evolutionary drafts model now finessed by Terrence into a more concordant and appealing wrapping. In this respect Bernard Baars' description of the Cartesian Theatre of working memory, is surely the most animistic description in neuroscience, has a more appealing rationale because it is so richly populated with conceptual actors having the personae of living agents.

Deacon then applies this directly to conscious intentional actions. For illustration, reading exemplifies the logic of teleodynamic work. A passive source of cognitive constraints is potentially provided by the words on a page. A literate person structures their sensory and cognitive habits to reorganise the neural activities constituting thinking. This enables them to do teleodynamic work to shift mental tendencies away from those that are spontaneous (such as daydreaming) to those that are constrained by the text:

“Although teleodynamic processes are incredibly complex, and an explanation of the structure of teleodynamic work is by far the most elaborate—since it is constituted by special relationships between forms of morphodynamic work—it is also the most familiar. So it may be helpful to first consider the human side of teleodynamic work before delving into the underlying dynamical structure of this process. Teleodynamic work is what we must engage in when trying to make sense of an unclear explanation, or trying to produce an explanation that is unambiguous”.

“In cognitive terms, orthograde teleodynamic processes may be expressed as goal-directed innate adaptive behaviors, spontaneous emotional tendencies, learned unconscious patterns of behavior, stream-of-consciousness word associations, and so forth. In social terms, orthograde teleodynamic processes may be expressed as common cultural narratives for explaining events, habits of communication developed between different groups or classes of individuals, conventionalized patterns of exchange, and so on”.

Here is where there is a scorpion-like sting in the tail, which is the his “insight” of the utility of the zeros that he notes arise from the hard problem of consciousness and other manifestations of subjectivity, which don't appear to arise from the reductionistic physical description. This revolves around his notion of *entention*:

“I propose that we use the term ententional as a generic adjective to describe all phenomena that are intrinsically incomplete in the sense of being in relationship to, constituted by, or organized to achieve something non-intrinsic. By combining the prefix en- (for “in” or “within”) with the adjectival form meaning something like “inclined toward,” I hope to signal this deep and typically ignored commonality that exists in all the various phenomena that include within them a fundamental relationship to something absent.”

Terrence's story starts out with great hope for conscious existence, invoking the possibility of causal openness:

“This opens the door to an emergent capacity to generate ever more complex, unprecedented forms of work, at progressively higher-order levels of dynamics, thereby introducing an essentially open-ended possibility of producing causal consequences that wouldn't tend to arise spontaneously. That is, we can begin to discern a basis for a form of causal openness in the universe.”

However, by adding in his dynamic interaction between his teleological constraints and physical causality, he introduces a second level of objective causal closure defined by his thermodynamics. Notice that he admits this is a belief, not an empirical fact:

*“By reframing the problem in these dynamical terms, **I believe** we will discover that rather than being the ultimate “hard problem” of philosophy and neuroscience, the subjective features of neural dynamics are the expected consequences of this emergent hierarchy. The so-called mystery of consciousness may thus turn out to be a false dilemma, created by our failure to understand the causal efficacy of emergent constraints.”*

In his closing passages, again stating this is belief, he attempts to nail the coffin of the zero or “absence” of the hard problem to it's ultimate RIP:

*“**I believe** that human subjectivity has turned out not to be the ultimate “hard problem” of science. Or rather, it turns out to have been hard for unexpected reasons. It was not hard because we lacked sufficiently complex research instruments, nor because the details of the process were so many and so intricately entangled with one another that our analytic tools could not cope, nor because our brains were inadequate to the task for evolutionary reasons, nor even because the problem is inaccessible using the scientific method. It was hard because it was counterintuitive, and because we have stubbornly insisted on looking for it where it could not be, in the stuff of the world. When viewed through the perspective of the special circular logic of constraint generation that we have called teleodynamics, this problem simply dissolves.”*

He then plays to the darkly shaded tune of these absences, holes or zeros:

"The subjectivity is not located in what is there, but emerges quite precisely from what is not there. Sentience is negatively "embodied" in the constraints emerging from teleodynamic processes, irrespective of their physical embodiment, and therefore does not directly correlate with any of the material substrates constituting those processes. Intrinsically emergent constraints are neither material nor dynamical—they are something missing—and yet as we have seen, they are not mere descriptive attributions of material processes, either. The intentional properties that we attribute to conscious experience are generated by the emergence of these constraints—constraints that emerge from constraints, absences that arise from, and create, new absences."

and in closing states that we are back to a purely objective causality, lacking any need for subjective existence:

"But this negative existence, so to speak, of the conscious self doesn't mean that consciousness is in any way ineffable or non-empirical. Indeed, if the account given here is in any way correct, it suggests that consciousness may even be precisely quantifiable and comparable, for example, between states of awareness, between species, and even possibly in non-organic processes, as in social processes or in some future sentient artifact. This is because teleodynamic processes, which provide the locus for sentience in any of its forms, are precisely analyzable processes, with definite measurable properties, in whatever substrates they arise."

Here is where the Wikipedia editor's comment was right: *"The book expands upon the classical conceptions of work and information in order to give an account of ententionality that is consistent with eliminative materialism and yet does not seek to explain away or pass off as epiphenominal the non-physical properties of life."*

The difficulty here is that it is both consistent with eliminative materialism and the only sense in which mind is now "not epiphenomenal" is that it has been completely explained away as simply as case of objective thermodynamic teleo-dynamics. This use of entention as a purely mechanical generalisation of intent opens up the floodgates to any form of AI that adopts the raw form of teleo-dynamics and directly to eliminative materialism, by supervening the entire scope of the subjective realm to a thermodynamic teleology that in no way captures the true nature of diversity, surprise, creativity or insight, except in the evolutionary model of random accumulation of adventitious and hence "useful" teleological information. Furthermore no such purely thermodynamic reality can in any way manifest itself subjectively, so it is not an actuality manifesting the subjectivity of any conscious living agent. Hence it in no way solves the hard problem any more than any purely mechanistic model of brain dynamics does. In this respect "Incomplete Nature" is simply addressing some of the easy problems around abstract functionality of brain states, in thermodynamic terms, not the hard problem itself.

Deacon has claimed that this teleology is so causally complete that it has automatically, in a purely descriptive account, rendered quantum reality irrelevant:

"It didn't even require us to invoke any superficially strange and poorly understood quantum effects in our macroscopic explanations in order to account for what prior physical intuition seemed unable to explain about meaning, purpose, or consciousness. ... More important, the scale at which we do unambiguously recognize ententional properties is vastly larger than the scale of quantum events, and in between there are only thermodynamic and chemical processes."

But this claim is self-fulfilling, as it stands precisely alongside the obvious fractal structure of brain tissue that likewise runs dynamically in a hand-shaking interaction between global wave states, cellular action potentials, and ion channels at the quantum level, modulated by edge-of-chaos transitions, and stochastic resonance at the unstable global tipping points when make-or-break situations where survival decisions are made, amid wave coherence sampling which is itself homologous with quantum measurement in the uncertainty principle. This is where we come full circle and have to recognise that, while Terrence did claim that teleological thermodynamics overlays quantum reality, he has in no way established that it has overruled it. In the evolutionary model, each adventitious mutation is an example of a single unrepeated quantum instance. His own analogy between evolution and neurodynamics implies that adventitious thought may arise likewise from a single quantum instability induced by an unstable neurodynamical tipping point and we know from recent research that the quantum world approaches the classical only under conditions of IID (independent and identically distributed measurements) as Gallego & Dakić (2021) have shown, which neither evolution nor neurodynamics conform to.

Fig 96: Title image to "Incomplete Nature" – the complete ablation of the subjectively conscious volitional mind in favour of thermodynamic abstraction.
My physically casual brain made me do it becomes teleological thermodynamics made me do it.

In his conclusion, Deacon sets out to claim this gives humanity hope of meaning in existence:

“Perhaps the most tragic feature of our age is that just when we have developed a truly universal perspective from which to appreciate the vastness of the cosmos, the causal complexity of material processes, and the chemical machinery of life, we have at the same time conceived the realm of value as radically alienated from this seemingly complete understanding of the fabric of existence. In the natural sciences there appears to be no place for right/wrong, meaningful/meaningless, beauty/ugliness, good/evil, love/hate, and so forth. The success of contemporary science appears to have dethroned the gods and left no foundation upon which unimpeachable values can rest. ... As I lamented in the opening chapter of this book, the cost of obtaining this dominance over material nature has had repercussions worldwide. Indeed, I don't think that it is too crazy to imagine that the current crisis of faith and the rise in fundamentalism that seems to be gripping the modern world is in large part a reaction to the unignorable pragmatic success of a vision of reality that has no place for subjectivity or value. The specter of nihilism is, to many, more threatening than death. By rethinking the frame of the natural sciences in a way that has the metaphysical sophistication to integrate the realm of absential phenomena as we experience them, I believe that we can chart an alternative route out of the current existential crisis of the age—a route that neither requires believing in magic nor engaging in the subterfuge of ultimate self-doubt. ... If quantum physicists can learn to become comfortable with the material causal consequences of the superposition of alternate, as-yet-unrealized states of matter, it shouldn't be too great a leap to begin to get comfortable with the superposition of the present and the absent in our functions, meanings, experiences, and values.”

But what Deacon has actually done is to screw down the death grip of true subjectivity even tighter. We end up with the opposite – eliminative materialism – rejecting the notion of mind and consciousness altogether as an archaic misconception, as Ryle has done, becoming nothing but a gap in the description of reality itself, substituted for by a regime of objective thermodynamics complementing physical materialism.

In a recent development (Kourehpaz et al. 2022), the arrow of time and the Boltzman distribution associated with thermodynamic entropy, which doesn't exist in quantum systems, which are time-reversible has been attributed to quantum chaos, thus meaning quantum reality and chaos are essential to the concept of thermodynamic time flow.

Hopeful Monster 6: Quasi-Particle Materialism

An interesting example of applying quantum processes to teleodynamic ideas is that of Roman Poznanski and coworkers (Poznanski et al. 2019a, b). Here they invoke a quantum process involving a variety of speculative quasi-particle like phenomena.

To start, I'll explain what I think is missing in Roman's pan-mat view of consciousness. Pan-mat is one of several theories of conscious brain function, in which a phenomenon, such as quasi-particles, that may well play a part in how the conscious brain functions, has been given a privileged status in a “hopeful monster” theory of consciousness that in this case depends on physical materialism and seeks to eliminate obvious exit routes in physics.

Organismic tissues constitute a unique state of matter in a self-organised phase transition between metal and insulator that creates a unique quantum-molecular paradigm. [Figure 81](#), shows that the myoglobin molecule, displays a series of fractal and self-organised critical properties that all organic molecules in tissue possess, from the origin of life, in a new state of matter, stunningly more advanced than the solid state physics of silicon. We simply don't understand or respect how tissues work because we don't understand they are macroscopic quantum phenomena possessing latent attributes of consciousness. Nottale (2014) & Turner & Nottale (2017), which the Pan-mat research cites show macro-quantum effects, via pseudo-quantum theories in which Planck's constant can be rescaled. But this is simplifying what is really happening because we can't just jig Planck's constant, so what they are displaying are genuine macro-quantum features that are actually held together by molecular fractality, from the quantum level all the way to the brain and universe as shown in [fig 1](#), so cell organelle and tissue structure is coordinate in a state of quantum fractal super self-organised criticality as a far from equilibrium self-organising system. This doesn't immediately look like a quantum fractal because, in living systems, genes have encoded the proteins to adopt useful fractal forms at the edge of chaos that themselves constitute dynamical quantum reality at the edge of chaos, but looks a little like a biological machine functionally. At the centre of the cyclone is the conscious brain, which is the ultimate cosmological interactive consequence of symmetry-breaking of the forces of nature.

The only meaningful empirical conclusion that can be drawn about the relation between subjective consciousness and physical reality is that “subjective conscious volition has efficacy over the physical universe” although this is an undecidable proposition, in the Godel sense, from the physical viewpoint, despite being certain from the Cartesian viewpoint: “*cogito ergo sum*”. Symbiotic Existential Cosmology sees this as an additional cosmological axiom of primal subjectivity at the quantum level which becomes fully manifest in eucaryote cellular and organismic consciousness.

The problem with Pan-mat is that it tries to limit all discussion to a classical viewpoint of physical materialism through an argument depending on analogy alone, stripping itself of the principles by which the hard problem can be solved: (1) It is empirically and theoretically impossible to demonstrate physical causal closure of the universe, or of the brain as a self-organising system, so founding a theory of consciousness on physical materialism is and remains unprovable, except as a kind of religious belief. (2) Roman and co-workers are using a social concept of multiscale organisation which is inadequate to the task, rejecting three key features of how the living universe works: (a) quantum reality, (b) self-organised criticality and (c) the intrinsically fractal nature of the symmetry-broken standard model of physics. No theory which neglects all three can have any hope of a successful description of life or intelligence in the quantum universe. (3) The actual core tenets of the theory are not empirically verifiable or even manifestly plausible. (4) It is based on quasi-particles through a quantum analogy when good science doesn't work on analogical assumptions.

As a field-like theory, the quasi-particle aspect has about the same strengths and weaknesses as other field-like theories of consciousness discussed earlier, but its claims to pan-experiential materialism are thus more problematic:

Quantum chemistry underpins the so-called 'quantum underground' where consciousness originates. Due to inherent uncertainty in electron localization, the weakest type of Van der Waals force, the so-called London force, exhibit quantum effects and the resultant dipole oscillations (see Hameroff (2008) for a review). London forces are quantum level instantaneous, but weak, induced dipole-induced dipole couplings, due to charge separation resulting in attractive Coulomb forces occurring between nonpolar π -electron resonance clouds of two or more neutral atoms, molecules or macromolecules.

We also assume that guidance waves and their resultant thermo-quantum fluctuations govern subtle internal energy leading to hierarchical thermodynamic transfer of information in the realm of preconscious. What is transferred from the macroquantum realm to the classical realm is information (theoretic) entropy as thermo-qubits containing information on the phase relations between molecular dipole-bound electron clouds of multiple systems.

The information we are discussing is intrinsic in the sense that it remains 'hidden' from the operational explanations of cognitive capacities. It is neither quantum information nor integrated information, but interconnected 'intrinsic' information associated with the internal thermo-quantum fluctuations that arise due to guidance waves transferring thermo-quantum internal energy by means of the macro-quantum potential.

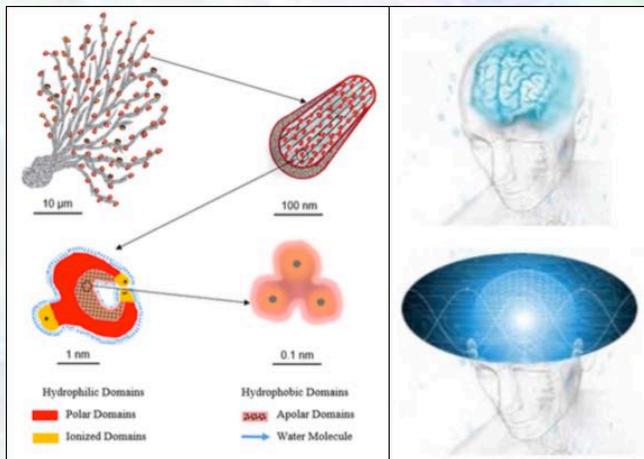

Fig 97: Left: (Top left) a neuronal branchlet studded with spines and (top right) shows a non-synaptic spine shaft containing cytoskeletal molecular proteins bound to actin filament networks within the spine shaft of uniform length. The quantised subspace is where pilot-waves originate at picometer scale (~ 0.1 nm) within apolar hydrophobic regions of actin-binding proteins shown (bottom left) form clathrate-like structures with water molecules. The electron clouds at ~ 10 pico-meter scale (bottom right) is an order of magnitude smaller than most chemistry transformations and measurements and therefore below physical chemistry. Right: There is a critical difference between identity theory (mind = brain) above and externalism (cosmic consciousness interacting with the brain) below. The brain only view of conscious space prevents any form of cosmic mind.

This process is illustrated in fig 97, where a similar quantum process to Hameroff and Penrose, using the London force is invoked on the dendritic web. Specific exceptional quantum processes are thus invoked which may not prove to exist. The "classical realm" is cited, as if it is a separate physical realm, when the entire process of dynamics is quantum non-IID. These do not couple to subjective consciousness, because they are just forms of hypothetical "information" in the brain dynamics acting as a cypher for consciousness, which is then considered irrelevant, in a form of "eliminativism" in favour of thermo-quantum teleology.

This becomes clear in (Poznanski et al. 2019c) where, in stating "against externalism" in the title, the teleodynamic process identifies itself with brain-mind identity theory against any cosmic mind description, even if consistent with dynamics of the default mode, drawn together in the name of dialectical materialism:

The difficulty in locating the mental states which are attributed to brain activity is explored in this paper through nonreductive physicalism, which claims that all mental phenomena can be explained by the functioning of their neurobiological correlates through information. That is, higher level of brain functioning with different properties with respect to their constituents emerges and influences causally brain activity. This is not emerging reductionism-unlike in philosophy of mind, we do not subscribe to different ontology from DiaMat (dialectical materialism), which claims that consciousness is not an immaterial spirit. How this happens is the notion of teleofunctional components with intrinsic information of the material component that includes activity in brain structure. This differs from externalism as shown in the figure through proto-consciousness or cosmic consciousness interacting with brain's neural dynamics. We are reduced to physical materialism, so the purpose and utility of the thermo-quantum extension is moot.

I also find the definitions and concepts to be metaphorical descriptions rather than a verifiable scientific theory:

It is usual to note that teleofunctions are distinct from the causal-role functions involved in functionalism. For example, with ordinary function the elements are irrelevant, while in teleofunction they are relevant because the function concerns what something is for and the notion of what something was selected for counts. This is a "teleological" notion of function, which can be minimally defined as the activity of the structure. Moreover, teleofunctions carry a value judgment or 'meaning' (unlike ordinary function, which carry only action or resultant effect). There is meaning attached to the interconnectedness of intrinsic information content of mental states and their interrelationship during the unification process. ... The integration of brain functions results in a new category because of the functionally-linked continuum that is referred to as teleosemantic hierarchy of intrinsic content of brain states. Since the quantum realm is characterized by indeterminism, i.e., non-causal effects, this is incongruent to nonreductive physicalism where quantum mechanisms must be acausal. The unification of mental states associated with the brain's hierarchical organization allows quantum-like causality to take on a subtle role in the brain leading to teleofunctionality. The unification of mental states arises from the teleosemantic hierarchy of interconnected intrinsic information content of mental states.

In Poznanski & Brändas (2020) the authors provide a sweeping philosophical justification to support their thesis, now described as pan-experiential materialism. The use of experiential is a misnomer because the authors state that panexperiential materialism claims that the mental-immaterial realm, just like the physical world, can be derived from matter waves, in an attempt to explain preconscious activity by an unproven claim of certain kinds of activity in the brain attribute "meaning" through thermo-teleodynamics. This forecloses on experiential consciousness, by claiming it is a distorted superstructural perspective on a deeper pre-conscious dynamic arising from the quantum thermal milieu and pure information gaining "meaning", using a purely objective physicalist description to use the brain's ability to use subconscious processing that may rise to conscious attention if it is coherently relevant, to devalue the core role of subjective consciousness, claiming to solve the hard problem through quasiparticle-enhanced pure materialism.

Poznanski et al. (2022) extends this description to give it more detailed theoretical support. I remain cautious about the scientific verifiability of this overall construction. Many of the descriptions are speculative and circularly self-fulfilling. The authors cite Bohmian mechanics extended to molecules, but Bohmian mechanics is inconsistent with particle creation and annihilation which bond formation and breakage involves. I thus have issues about the verifiability of the sub-molecular thermo-teleoquantum description and its assuming of the role of 1pp experiencability, in a purely materialistic teleological form, which effectively denies subjective conscious volition over the physical universe and thus becomes a form of preconscious epiphenomenalism:

Experienceability is the capacity for an experience that occurs preconsciously and serves as an affective function that explains experience as a testament of consciousness. We base our model on the meaning of the feeling-as-information hypothesis suggesting that evanescent meaning arises from patterns of intrinsic information-carrying physical feelings. In other words, evanescent meaning as information gives form to feelings, meaning sentience as the capacity of feeling. Since the information is intrinsic, physical or raw feelings are hidden from phenomenal introspection. ... Preconscious experienceability is realized physical feelings with vast numbers of atomic microfeels formed as physical feelings (holons) in informational holarchies.

The notion of "microfeels" bears an interesting comparison with "raw feels" cited in the [Stanford](#) account of dualism: "At least since the time of Ryle's *Concept of Mind* (1949), it has been assumed that thinking can be handled in a dispositionalist way; so only sensations or 'raw feels' constitute a problem for the physicalist". This is then identified with π -orbital electrons, but all heterocyclic molecules, from nucleic acid bases, through tryptophan to the porphyrin ring have delocalised electrons. They are integral to all biological processes. To identify experiencability with π -orbital electrons in a specialised brain dynamic is facile and confining to other processes:

The feeling-as-information hypothesis can be applied to nonpolar hydrophobic regions, which are non- electrolytic regions of fatty acids and intersect with lipophilic membrane proteins' domains of mainly partially holistic amino acid units. Here holistic is defined as the molecular wave function expressed over many delocalized electrons where parts of molecules are partially holistic with a specific internal energy that keeps it together by canceling the classical potential energy and, as shown in long-range order in a thermalized milieu must partially keep π -electrons phase differences in the self-organized molecular orbital only in the absence of classical potential energy.

The same problem occurs with the discussion of quantum entanglement:

Our theory posits that nonlocal holonomy results from negentropic entanglement of nonintegrated information through the 'negentropic force'. Therefore, there can be no "spooky action," and nonlocal holonomy in brains is through negentropic entanglement. The nonintegrated information juxtaposes several mechanisms on the quantum / classical regime boundary.

The explanatory gap between subjective consciousness and neurodynamics is explained through classical information:

We have proposed a solution to close the explanatory gap. Classical information theory measures the decrease in uncertainty, for example, when consciousness ends, and memory begins. The spontaneous potentialities are environmentally influenced. Intrinsic information is Fisher's information that relies on uncertainty and, at the fundamental level, comprises negentropic influences that carry molecular-embedded microfeels of meanings that comprise semantic information at a large scale. This latter process involves the capacity of negentropically interconnected partially holistic molecules to mutually affect, i.e., in-form, each other. This is the basis of negentropic entanglement. Although we propose a molecular approach, there is a problem with coupled process structures, in-forming each other on all levels of a neural organization. A dual-aspect theory of information, where one is classical and non-classical, is a wedge to close the exploratory gap between the mind and the body.

Quantum models of consciousness are then discarded in favour of "evanescent molecular micro-feels":

Finally, quantum models of consciousness are unrealistic from a biological perspective because the brain is an open quantum system. As Tegmark criticized the Orch OR model, the wave function has rapid decoherence. Our model is based on dissipative phenomena and does not suffer the same problems as other quantum models. No informational field continuously and permanently gives off the "radiance of consciousness". What we postulated are molecular-embedded microfeels that are evanescent. Therefore, by our definition, consciousness represents quanta of information (i.e., the temporal waveform in phase-space) that in each moment actualizes into conscious experience certain selections of the unconscious molecular embedded microfeels that, for long periods, resting in potentiality, constitute the preconscious experienceability.

Poznanski, in later statements, defines his cosmological point of view as follows:

Panexperiential materialism does not deny mentalism but puts it as part of the canopy of intrinsic processes, includes understanding relationships in their wholeness, and methodologically requires a multiscale approach. In panexperiential materialism, there is a self-referential identity theory, which allows for all possible relational facts, objective and subjective, intra- or interpersonal, enduring or dynamic, effectuated in structures of the holarchy to fundamental levels without the need for integration. The relational co-existence of the holons within the holarchy is a crucial distinction between holism and materialistic dialectics based on emergent causal effects. There will be effective feedback loops of intrinsic processes and experiences otherwise hidden in identity theory. Qualitative effects come about from self-referentiality and its non-Turing computational character. It is based on Sperry (1970) that subjectivity is not a qualitatively distinct category from physical processes.

Roman, in personal communication 5 Jul 2022 specifically concedes these quasi-particles cannot be empirically validated, but are nevertheless in reality subjectively first person conscious:

*The quasiparticles in the brain are not capable of being observed.
The complex nature of these signals makes them a theoretical petri dish but they are 1pp in reality.*

However, on 1 Mar 2023 in regard to (Alemdar et al. 2023), he states:

*Consciousness is a quasi-polaritonic⁴⁴ wave, see papers recently published.
Quasi-polaritonic waves that are moving result in standing waves when consciousness ends and memory starts.*

Polaritons are hybrid particles made up of a photon strongly coupled to an electric dipole. Examples of such a dipole include an electron-hole pair in a semiconductor, which forms an exciton polariton, and the oscillating electrons at the surface of a metal, which creates a surface-plasmon polariton. Obviously we don't think a transistor is conscious, although it involves polaritonic waves. If we are dealing with the same type of quantum entity in the brain why is one conscious and the other not? This is the same type of critique as Merker et al. (2022) concerning II.

Roman: As Sperry (1970) suggested, consciousness must be investigated objectively and we have done this through a multiscale lens (Alemdar et al. 2023). Starting with quasiparticles as the minimalist material composition of the dynamical brain where interferences patterns between incoherent waves of quasiparticles and their quantum-thermal fluctuations constrain the kinetic internal energy of endogenous molecules through informational channels of the negentropically-derived quantum potential. This indicates that brains are not multifractal involving avalanches but are multiscale, suggesting that unlike the hologram, where the functional interactions occur in the spectral domain, the

⁴⁴Polariton: quasiparticle resulting from strong coupling of electromagnetic waves with an electric or magnetic dipole-carrying excitation.

spatiotemporal binding is multiscale because of self-referential amplification occurring via long-range correlative information.

Chris: Multiscale is an ill-defined concept to do with scales of interaction in human societies (Olteanu et al. 2019). Neither is multifractal adequate, but denying quantum fractality outright is in empirical conflict with molecular biocosmology scale transitions (See [figure 51](#)). You are welcome to confine your research to Sperry, but it is inevitably pure physical materialism which will never bridge the explanatory gap.

You have just shown that your subjective conscious volition produced your e-mail reply, showing clear evidence you have subjective conscious volition you witnessed composing and dispatching your e-mail. That IS evidence! To deny it you either have to admit you are a zombie, who can't consciously affect the universe, or pronounce some epiphenomenalistic or fully materialistic jargon to deny the volition you know you exercised. We can all tell from the tenor of your reply that you consciously knew what you were doing even in the age of chatGPT.

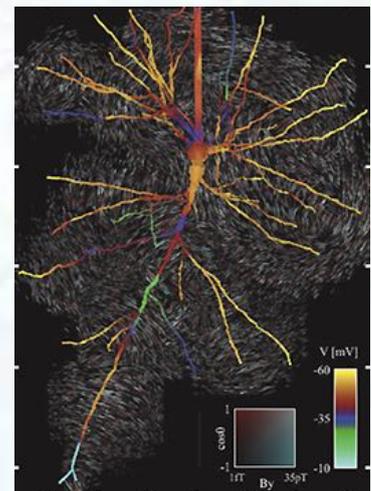

Roman: Quantum consciousness remains unproven and does not fit into quantum biology, but multiscale neuroscience does.

Chris: Quantum consciousness is not in the same category as multiscale neuroscience, consciousness is subjective and neuroscience is physical. You can't validly refute one on the basis of assuming the other. The statement that quantum consciousness doesn't fit into quantum biology is a contradiction, as consciousness does fit integrally into animal biology. Nothing in your theory is proven or provable, since you admit that: "The quasiparticles in the brain are not capable of being observed".

Roman: We have quantum analogs as classical properties of the quantum realm that fit onto a molecular scale of brain functionality. At this scale, phenomenal consciousness is a hybrid quasiparticle wave. It depends on its material property and represents a gateway to memory through the transfer of information, a derivative of energy transduction.

Chris: This is simply a statement of faith in pan-experiential materialism, which fails the hard problem extended to volition, as it effectively claims identity between polaritons and subjective consciousness. But this fails the same test as Merker et al. (2022) posed over ITT, since transistors and many other non-conscious systems utilise quasi-polaritonic waves but are not conscious. Why is phenomenal consciousness specifically and exclusively a hybrid quasi-particle wave at the molecular scale? Every molecule is a quantum entity, but it is only phenomenal consciousness if it also has a subjective phenomenology. You are in effect assuming one kind of quantum entity is a classical property and at the same time it is conscious – by analogy.

Fig 98: Reconstructed pyramidal neuron from macaque with the simulated electrical activity and corresponding magnetic field. The "two brain" theory postulates a second electromagnetic ghost in the electrochemical "machine" of the brain operating in complementary parallel.

Roman: It refutes the premise of dual aspect information since quantum information is not involved. I am not referring to weak dualism concerning the "outer core" of the quasi-polariton. This is because when we view through a multiscale lens, information has various layers of the physical attribution/functionality that constitute the mind. The "outer core" is where ions collect, which is associated with cognition. The "inner core" is the unique material composition of consciousness – the quasiparticles and their interference patterns.

We must further assume that quasi-polaritons as quasiparticles are archetypal quantum analogs of conscious experience that naturally depend on cognitive dynamics attributed to the arrangement of ions encasing the polaritonic wave. They are subjective because they encase the cognitive aspects of organisms uniquely.

Chris: You are claiming a form of pan-experiential materialism which does not appear to link to consciousness except by analogy. The notion of an inner core of consciousness of quasi-particles and their interference patterns and an

outer core containing ions as cognition is scientifically unverifiable and has no conceptual basis in quantum uncertainty any different from a purely physical phenomenon, such as a transistor.

Roman: What is consciousness? Many people of the old generation assume it is neural networks. The biggest change that we found is that consciousness is precognitive and the neural networks are entrained for consciousness to be expressed. Quantum mechanics is also irrelevant (see quantum statistical thermodynamics via Nelson 1966 reference). Consciousness does not have an electrical component and is therefore, not within the electro-ionic brain of the two-brains hypothesis but resides in the electromagnetic brain (Bercovich et al., 2017). Here, ions are not flowing as currents; the thermodynamic state creates the brain's internal energy, which includes covalent energy between molecular bonds and dispersion energy due to van der Waals bonds. Consciousness is a process that carries an integrative function, arising when the brain's internal energy is dynamically transformed (i.e., changes) by van der Waals bonds.

Chris: You seem to have an electromagnetic ghost lurking in the electrochemical machine. That is interesting and deserves critical attention.

Consciousness is the active process of attending to and engaging subjective experience either internally, or through the physical senses. Your definition of consciousness above is dependent on acceptance of the theory as a whole and your claim that "The act of understanding uncertainty is consciousness" is also unnatural as it derives from an abstruse definition of autopoiesis – the "central dogma" of information (Cárdenas-García 2022). It has nothing whatever to do with quantum uncertainty. Your definition of pre-cognitive is ill-posed because precognitive dreaming for example is pre-experiential *deja vu* – not pre-rational. Furthermore saying it is pre-cognitive is also ambiguous as to whether pre-cognition is experienced at all. The two brains hypothesis (Bercovich et al., 2017) is interesting but highly speculative.

Your published definition of consciousness (Alemdar et al. 2023) is:

*The meaning essential for understanding 'uncertainty' as a definition of consciousness falls into the category of semantic information in the central dogma of information (Cárdenas-García, 2022). ... **The act of understanding uncertainty is consciousness.** It does not need to make sense for "understanding" to take place. As the term "understanding" in the above definition of consciousness is precognitive, i.e., consciousness is intrinsic to affect but not to cognition. ... As per the central dogma of information, semantic information interactions with syntactical information is when conscious recall arises instead of memory, and only in the presence of 'uncertainty' is memory reconsolidated (Solms, 2017).*

The central dogma is purely about info-autopoiesis which is teleological, but not an innovative process, which subjective consciousness is. Therefore your entire holonomic argument rests on autopoiesis and multi-scalar system analysis, which in no way validly rebuts self-organised criticality or fractality. Your "anti-quantum" approach is cited as deriving from a Brownian motion classical interpretation of quantum mechanics (Nelson 1964) and the entire case is highly speculative. While I like the citation of an electromagnetic ghost in the electrochemical machine, I can still see no experimental evidence in vivo or in vitro to support this.

The abstract to The Central Dogma of Information (Cárdenas-García, 2022) states:

Info-autopoiesis or the self-referenced, recursive, interactive process of information self-production that engages all living beings in their efforts to satisfy their physiological and/or relational needs relies on Bateson's difference which makes a difference. Living beings, as active manipulators/observers of their environment, derive meaning from the sensorially detected motion of matter and/or energy in the Universe. The process of info-autopoiesis in humans is found to be triadic in nature and incorporates the simultaneity of a quantitative/objective perspective with a qualitative/subjective perspective. In this process of meaningful engagement with the environment, humans create and transform endogenous semantic information into countless expressions of exogenous syntactic information, which is synonymous with ordered material structure and artificial creation.

In my understanding panexperiential materialism doesn't explain "what it is like" to be consciously aware. Understanding relationships in their wholeness is an objective construct to make an abstract objectively "out there" model of mentality as an autonomous "homeostatic/teleological" feedback system as a physically definable form of organismic agency in a purely biological sense. It is thus a functionally extended form of pure materialism. This is simply not what happens. Conscious experience is self-manifesting. It is irrefutably present to our existential awareness. Our experiential purview of reality is entirely derived through subjective conscious experience, qualitatively entire as a distinct category from physical processes. Subjectivity can only be experienced not observed. We experience only through our subjective consciousness and infer the physical world view from consensual conscious

sensory experiences of the world at large and learn only indirectly from trial and error that we are biological organisms vulnerable to physical misadventure.

I provisionally accept that that living systems may exhibit a degree of short-term teleodynamics, particularly arising from their evolutionary context, but I see it as a limited necessary but insufficient condition for conscious existence. The authors may be speculating on plausible sub-molecular processes that underly normal brain functioning, consistent with an interface to, and potentially informative about, subjective consciousness, but whether these explain the hard problem or the existential nature of existence remains unestablished.

Strong Artificial Intelligence verses Understanding Natural Consciousness

We have seen that a number of neuroscientific theories of consciousness including ART, AST and IIT cite the possibility of their use in artificial neural networks supporting artificial intelligence. However some authors are interested in exploiting their discoveries for fame or profit. During the debate with Roman Poznanski on his theory of pan-experiential materialism, it emerged that he had trademarked a definition of consciousness with a view to it being used entrepreneurially in "Strong AI".

Roman: "The act of understanding uncertainty is consciousness" (This definition is copyrighted®12/12/22). It does not need to make sense for "understanding" to take place. As the term "understanding" in the above definition of consciousness is self-referential and precognitive, i.e., consciousness is intrinsic to affect but not to cognition. Experimental findings from acknowledged work on savants indicate that the disintegration of spatiotemporal patterns of neuronal activity can bring about lower-level recall of vast raw less-processed information at the expense of cognitive functions, such as conceptual thinking. Consciousness is a savant-like process in all of us with a difference. Instead of raw sensory information, it is endogenously produced semantic information as raw physical feelings.

Brian Josephson: Really? 5 Things You Can't Copyright That catchy slogan you came up with for your business? No dice on a trademark. The good news is that while not protected by copyright, if it pertains to your business (for example, goods and services), it can be protected with a trademark. Also exempt: Names, Titles, **Short phrases or expressions**, Product descriptions, Pseudonyms, Titles of works, Business names

Cathy Reason: However, I notice that he wrote ® rather than ©. So did he in fact register his phrase as a trademark rather than asserting copyright, which it seems would have been allowed, if no one else had done it before him?

Brian: This may help: *The registered trademark symbol, ®, is a typographic symbol that provides notice that the preceding word or symbol is a trademark or service mark that has been registered with a national trademark office. A trademark is a symbol, word, or words legally registered or established by use as representing a company, product or service.*

Chris: I copyrighted this idea as author under creative commons on 31/10/21:

Consequences: *Affirmation of human subjectively conscious physical agency and legal responsibility. Occam's razor is reversed, eliminating pure materialism, as inconsistent with conscious physical volition. Brain dynamics is not causally closed due to quantum uncertainty, enabling subjective consciousness to seamlessly participate in the uncertain instabilities of coherent processing without resulting in neurodynamic causal conflict.*

Uncertainty and mind: *The action of mind on brain necessarily arises from modulating the "random" aspect of quantum uncertainty in edge of chaos brain processing. This enables volitional will to intervene in the brain without disrupting the partial causal closure in brain processing in the uncertain quantum universe. In this sense, classical causality is replaced by quantum consciousness. It provides plenty of room to affect the computationally-intractable uncertain outcomes in evolutionary survival, using both subjective anticipation inherited from single celled eucaryotes a billion years before neural systems evolved and historical experience generated by cognitive processes.*

Symbiotic Existential Cosmology is CC BY-NC-ND 4.0, free to use intact and cited, but not to use uncited pieces of. SEC lists on Research Gate as published June 2021. The scientific overview I quoted lists from September 2021.

Roman: "Consciousness as uncertainty" is not what I suggested to be copyrighted: "The act of understanding uncertainty is consciousness".

Chris: Yes but it's wrong as it stands. The act of understanding uncertainty is conscious, but it's not consciousness. We need to do more than understand it, we need to act upon it to survive, which is why volition is pivotal. Watching a red rose is an act of conscious certainty, that it's not an alligator, or any other threat, except from its thorns.

I have a succinct cosmology whose thesis is centrally that subjective consciousness volition acts upon the physical universe exclusively through quantum uncertainty to avoid causal conflict as well as anticipating environmental threats rather than just "understanding" them. It's an important key additional axiom to quantum cosmology (and neuroscience). I don't want to see spurious later "copyright" claims distracting from its originality.

Roman: You are right. It is not yet a trademark unless it is used in business for 3 years. Nevertheless, I put that in just to stop others from taking the sentence. Yes, Mark Solms did mention something partially in line with the sentence but I believe it was not the entire sentence verbatim. This has nothing to do with quantum uncertainty.

Chris: All uncertainty arises from quantum uncertainty. It is an inescapable fundamental cosmological principle. All environmental uncertainty, as conceived of in neurodynamics, or the sort of uncertainty that Solms talks about in terms of strategic survival ultimately comes from contextual instabilities derived from quantum uncertainty.

The fundamental discovery in Symbiotic Existential Cosmology is the link between subjective conscious volition, quantum uncertainty and organismic survival, so neural processes are interactive manifestations of uncertainty as a cosmological principle. This means I have the copyright on this cosmological premise, not you Roman, nor Mark.

The final point is that it is impossible to eliminate quantum effects in the brain because the fractal non IID (independent, identically distributed quantum measurements) nature of neurodynamics means no convergence to the classical interpretation takes place because each event changes the context. Hence all the assumed non-quantum processes are quantum dynamics. So the notion of classicality in neurodynamics is invalid.

Conceiving the brain as a prediction machine cannot be done classically because the part that corresponds to conscious volition is collapsing the alternative Schrödinger cats of informational prediction, completing the prediction machine in free will. Consciousness corresponds to uncertainty because the computational aspects of prediction don't need to be conscious, but the uncertain aspects are uncomputable.

This doesn't mean we need dedicated quantum pathways like Hameroff & Penrose's model, nor do we need specific quasi-quantum classical pathways like Roman's polaritonic waves. We just need to respect the broad brush strokes of empirical neuroscience with the added quantum indeterminacy, as in SEC because tissue is the most exotic form of quantum material in the universe, quite unlike solid state physics excitons and quasi-particles, which require low temperatures and by contrast can readily take place in the thermodynamic milieu at 25-37°C.

Alfredo Pereira: I am puzzled because almost everybody agrees that phenomenological consciousness involves three mental functions: *cognition, affect and action control*. How to reduce consciousness to one cognitive concept, namely to reduction of uncertainty? The big Cartesian error remains, identifying consciousness with certainty. If we remain uncertain about something we cannot be conscious of it?

Chris: The problem with *cognition, affect and action control* is that it is conflating things which don't need to be subjectively conscious with those that do, so the picture gets muddled. We aren't identifying consciousness with certainty, because then the process is essentially over, whether it is "aha" or a decision-making process leading to action upon the physical universe. Processes like *cognitive thought* are easy to represent as physically-determined computational processes which can be expressed logically and so could be handled unconsciously and which we consciously perceive as a foregone conclusion. *Affect* is too vague because it is associated with ill-defined feelings which are limbic-system responses essential to survival, such as love, hate, disgust, contempt, and fear. *Action control* hints at volition, which is preceded by decision-making at a higher level, where the source becomes elusive.

A completely different way of dealing with the really creative questions, deeper in the intuitive process of subjective conscious decision-making is to view neurodynamics as a fully quantum process, in the most exotic quantum material in the universe, in which the wave aspects consist of parallel excitation modes representing the competing possibilities of response to environmental uncertainties. If there is an open and shut case on logical, or tactical grounds, this one will win out pretty much in the manner of Edelman's (1987) neural Darwinism or Dennett's (1991) despised multiple

drafts. In terms of quantum determinism the non-conscious processes form overlapping wave functions, proceeding according to deterministic Schrödinger solutions, (von Neumann type 2 processes), but in situations where subjective consciousness becomes critical to make an intuitive decision, the brain dynamic becomes an unstable tipping point, in which system uncertainty becomes pivotal (represented in instability of global states which are in turn sensitive to fractal scales of instability to the molecular level). Subjective consciousness then intervenes causing an intuitive decision through a (type 1 von Neumann) process of wave function collapse.

From the inside, this feels like and is a choice of "free-will" aka subjective conscious volition over the physical universe. From the outside, this looks like collapse of an uncertain process to one of its eigenfunction states which then become apparent. There is a very deep mystery in this process because the physical process looks and remains uncertain and indeterminate, but from inside, in complete contradiction, it looks and feels like the exercise of intentional will determining future physical outcomes. So in a fundamental way it is like a Schrödinger cat experiment in which the cat survives, more often than not i.e. we survive.

Roman: As for copyright, it can if used in entrepreneurship, like Strong AI development. Do you all know that the world now has nothing but weak AI? Google invested 500 million in DeepMind to squeeze sentience out of it. They will exploit it until they see that blood cannot be squeezed out of the rock. ... Yes, not copyrighted but trademark. TM. Copyright law applies after 15 or more words are copied.

Whit Blauvelt: Trademarks, with or without registration, require the mark be established in regular use in trade, in sale of goods or services, and not in conflict with any prior marks. Enforcement is a matter of civil action. Your odds of winning a trademark infringement suit based on some phrase written here are roughly zero/infinity.

Chris: You can't copyright "The act of understanding uncertainty is consciousness" as a process in Strong AI. It's not a product or process. None of the concepts are clearly defined. This would mean that every Turing computation that terminates is conscious, since it has "understood" the uncertainty of the invoked algorithm by solving it.

Roman: Our work on active consciousness suggests that consciousness is in the hand of man, not god, and therefore there is a way for the development of Strong AI. I am pleased with this progress. It will not only change the world but put DeepMind out of business. In the year that Strong AI stood up, I greatly appreciate that you don't send me emails to my other email or send me emails on metaphysics.

Chris: It's in the mind of man but should it be in the hand? The hand of God vs hand of man statement is a statement of serious concern. People are beginning to get worried that you are trying to claim intellectual property rights over the very notion of consciousness, which we all possess, in the same way the US failed to ratify the 1992 Rio Biodiversity Convention and still hasn't, to potentially claim ownership of the world's genes.

We already have too many neuroscientists like Graziano's AST conflating recursive biological attention with artificial neural nets. It is really irresponsible for materialistic neuroscientists to engage in the mechanised degradation of the biological consciousness we all share, in favour of classical neural nets or other technologies with or without transistors and other polaritonic components. Putting this in the context of a claim to somehow author Hard AI on a patentable basis is both unethical and pretentious given the IBM definition cited by Google:

Strong AI aims to create intelligent machines that are indistinguishable from the human mind. But just like a child, the AI machine would have to learn through input and experiences, constantly progressing and advancing its abilities over time.

I don't see how this is remotely achievable without an organoid approach. The idea you can do better than the entire evolution of the human genome since life began, with some sort of artificial organoid is more than a stretch of credibility, which raises very serious ethical doubts. And what a diabolical mission to even attempt. The literal Frankenstein of consciousness! In fact a cited co-worker of Poznanski has published on the use of sentient organoids made of a chimaera of a human organoid and bacterial and synthetic sensors fig 99b (Periera et al. 2023).

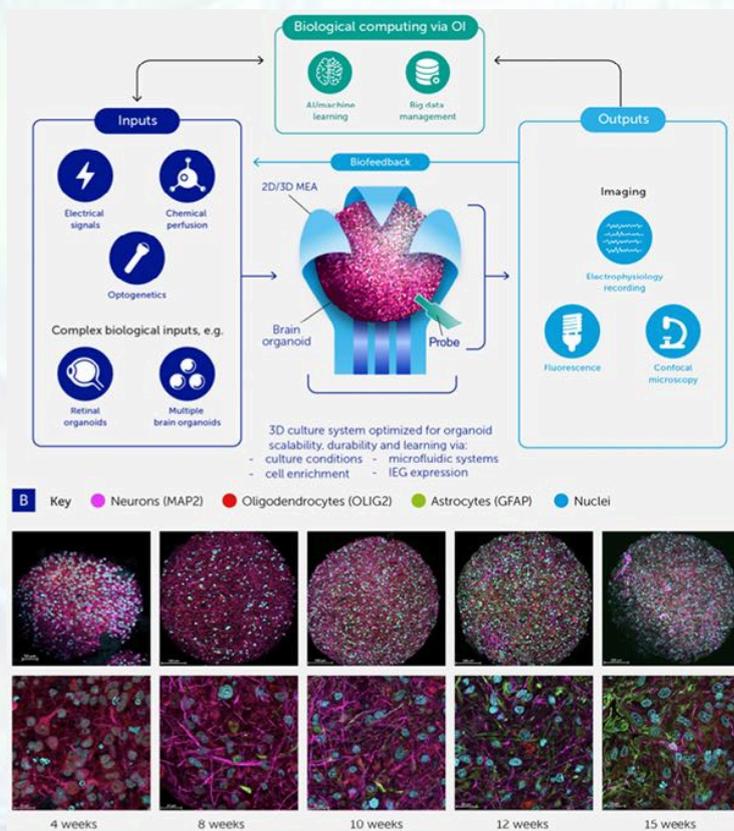

This morning, I noticed the Quantum Biology group had posted the link below to Smirnova et al. (2023) whose research team is headed by Thomas Hartung of Johns Hopkins, who is collaborating with the DishBrain team that taught an organoid to play pong (Kagan et al., 2022, Ledford 2022, Bowler 2022) aiming at a comprehensive plan for organoid super-computing and Hard AI.

"The beautiful and pioneering aspect of this work rests on equipping the neurons with sensations – the feedback – and crucially the ability to act on their world," says one of the authors, Professor Karl Friston, a theoretical neuroscientist at University College London. "Remarkably, the cultures learned how to make their world more predictable by acting upon it. This is remarkable because you cannot teach this kind of self-organisation; simply because – unlike a pet – these mini-brains have no sense of reward and punishment," he says.

"Let's say upfront that this is not a brain. Not even close. The human brain has somewhere in the region of 86 billion neurons. Even a mouse has 70 million. The team suggest DishBrain has a similar number of neurons to a bumblebee". "Even if DishBrain did have 86 billion neurons, we just don't know enough about the human brain to be able to create anything resembling a human brain".

"The brain has a complexity that cannot currently be replicated in a dish. The sheer number of cell types, the dynamics of the synaptic input they receive, and the neuromodulatory processes are not easy to replicate," explains Associate Professor Lucy Palmer, the head of the Neural Networks Laboratory at the Florey Institute.

This illustrates that DishBrain, was only the beginning and we are rapidly entering an era where strong AI, and my claim that realising his hypothesis would require an organoid approach was prescient (Brofiga & Massobri 2022).

"Nowadays, we are able to replicate many human neuronal types and peculiar brain regions in the form of engineered neuronal cultures, like neurospheroids or brain organoids, directly from embryonic and human induced pluripotent stem cells (hiPSC), and to couple them to a technological counterpart (i.e., chip).

"A full-sized human brain is not able to compute to the level of a supercomputer, but numbers-wise, they're not far off. Compared to a supercomputer, our human brain has a similar speed – around 1 exaFLOPS. Memory and storage units are still better in the human brain than supercomputers. For all human brains' flaws, they're also incredibly compact and low energy compared to a supercomputer."

Fig 99: Game plan for 'organoid intelligence'.

Already public discussion has run with the question whether such organoids are conscious, and the issue of trade-marking a definition of consciousness is red hot, so we all need to take stock now before it's too late to even comment. *Although the company calls its system DishBrain, the neurons are a far cry from an actual brain, Kagan says, and show no signs of consciousness. The definition of intelligence is also hotly debated; Kagan defines it as the ability to collate information and*

apply it in an adaptive behaviour in a given environment.

"The Australian company behind 'Dishbrain' (which learnt to play Pong last year) is collaborating with scientists at Johns Hopkins University in the US, whose research paper has outlined how these 'biocomputers' could allow us to understand memory, learning and other integral parts of human understanding. They also suggest it could rival supercomputers or AI. The crux of the paper, published in *Frontiers in Science* is a term called 'organoid intelligence' – this is the new field that will study small groups of human neurons that can learn, remember, and even understand its environment."

The Dishbrain team also controversially used the word 'sentience' in their paper, and so started a long line of questions about what makes something sentient, what makes consciousness and even intelligence? But this new paper suggests this is only the start. "We are talking at the moment really about the very basics," says Hartung. "It will take certainly many years before we reach the intellectual capacity of even a small animal."

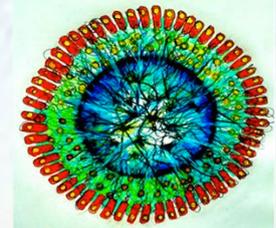

Periera et al. (2023) outline the following approach:

We predict the emergence of conscious experiences in the first-person perspective of the brain organoid, motivating the system to compose creative works, recombining the dynamic patterns previously presented. ... In this context, a scientific revival emerges,

which seeks not a return to a primitive state, but a transcendence of the human-nature relationship mediated by the very intelligence of the machine.

Enable the use of the brain organoid in "post-humanist" projects for the preservation of sentience, both demonstrating the mentality intrinsic to nature and contributing to human "reconnection" with the information richness of nature; ... In our foresight, Sentiomics has the potential to be the next step in a sequence of developments for the study and promotion of biodiversity and natural forms of mentality, moving forward in relation to successful projects of identification and preservation of genomes and proteomes.

Fig 99b: A genetically engineered bacterial network (colored red) connected around a brain organoid (colored blue; the intensity corresponds to hypothetical neuron firings) by means of a bio-sensor composed of a synthetic interface device to hypothetical neuron firings) by means of a bio-sensor composed of a synthetic interface device made of graphene (green) and golden quantum dots (yellow) to deliver natural bio-signals to the organoid. The bacteria have the role of transducing dynamic patterns from the Amazon Rainforest organoid (Periera et al. 2023).

Their approach is a two-phase one different from Poznanski's hard core panexperiential materialism.

Ways of feeling are studied in two modalities:

(A) As the universal set of patterns of Sentience, which we call Sentiomics;

(B) As species-specific and individually different sets of qualitative subjective experiences, which we call Qualiomics.

Qualiomics is, of course, a difficult issue for conventional science, as stated in the "hard problem of consciousness", because it leads to the much-discussed distinction of first- and third-person perspectives. There is an important difference between the capacity of feeling and emotion: while the first is a basic phenomenon possibly present in (almost) all living systems, the second is a higher-order phenomenon. The study of conscious emotions belongs to the domain of Qualiomics, a field of knowledge constructed with first-person perspective approaches. Sentiomics is more amenable to a scientific (empirical, experimental, and hetero-phenomenological) treatment than Qualiomics.

The problem solving dynamics in in vitro neuronal networks have been found to approach criticality in game-solving challenges similar to the dynamics attributed to conscious brain states however, by contrast in the 'resting state it is subcritical, unlike conscious brains, where the resting state is accompanied by active rehearsing of impending crises. Habibollahi et al. (2023) used an in vitro neural network of cortical neurons that was trained to play a simplified game of 'Pong' (Kagan et al. 2022) to demonstrate Synthetic Biological Intelligence (SBI). We demonstrate that critical dynamics emerge when neural networks receive task-related structured sensory input, reorganising the system to a near-critical state. Additionally, better task performance correlated with proximity to critical dynamics.

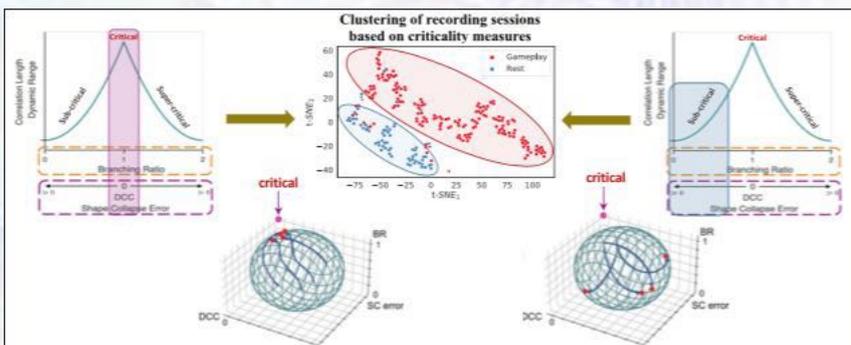

Fig 99c: Avalanches are utilised to examine the criticality metrics in the neuronal network's activity patterns to identify the working regime of each recording in terms of being sub-, super-, or near-critical. The same measures of criticality are used to cluster the recordings between two groups of Gameplay and Rest. The recorded neuronal activities are then employed to extract the 3 metrics of criticality (namely Branching Ratio (BR), Deviation from Criticality Coefficient (DCC), and Shape Collapse error (SC error)) which are

found to move towards the critical point during Gameplay and move further from that point during Rest (Habibollahi et al. 2023).

The human brain has taken 3 billion years to evolve. We are the climax of intelligent life in the universe as we know it. We are already being taken over by soft AI, with concern about the immanent tipping point caused by chatGPT. People are losing employment and a meaningful role in human society. We are trashing the biosphere from which we evolved with no real confidence of a living future. Is spawning a synthetic world made of our own brain cells the right course of action, when we still can't agree on what consciousness actually is? I repeat my concern that this is a critical ethical issue we all need to understand and take a clear position on. Do we really want to embark on a Brave New World of "Strong AI", in which we are taken over by supercomputing human brain cell Frankensteins? We can't just let it "stand up" as you say and walk by itself. What kind of Tragedy of the Commons (Hardin 1968) of consciousness is this potentially invoking? The use of human brain cells to make super computers and/or Hard AI needs to be

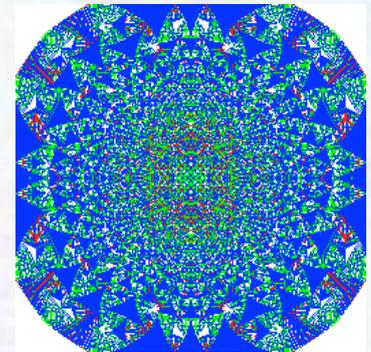

comprehensively assessed beforehand for ethical use, just as human germ-line genetic modification needs to be. We need to make a determination in advance that if “organoid intelligence” is a feasible biotechnology, is it actually desirable and will it help protect the future of Homo sapiens?

The Critically-Tuned Cortex at the Edge of Chaos

Associated with edge-of-chaos dynamics, the conscious brain is also cited as being in a state of self-organised criticality as being fine tuned in a phase transition between subcritical and supercritical states. This applies to many features, not just the neurodynamics, but to the network connectivity. Given only weak connections, neurons typically activate independently of each other, and the pattern of network activity is stochastic. The number of neurons activated in the last layer will tend toward zero because weak connections dampen the spread of activity. But too strong a set of connections is also counterproductive. One active strongly connected neuron activates multiple other neurons, spreading activity until nearly all the neurons in the final layer are active. Activity gets through, but this saturation does not let you accurately guess whether I activated one neuron in the first layer or all of them. The amplification has washed away most of that information. In the intermediate “critical” case, avoids both pitfalls and the proportion of neurons activated is roughly preserved across layers.

Fig 99d: [Abelian](#) simulation of the fractal avalanches in a sand pile.

Self-organised criticality (SOC) is a property of dynamical systems that have a critical point as an attractor. Their macroscopic behavior thus displays the spatial or temporal scale-invariance characteristic of the critical point of a phase transition, but without the need to tune control parameters to a precise value, because the system, effectively, tunes itself as it evolves towards criticality. The concept was put forward by Bak, Tang & Wiesenfeld (1987), and is considered to be one of the mechanisms by which complexity arises in nature. Its concepts have been applied across fields as diverse as geophysics, physical cosmology, evolutionary biology and ecology, economics, quantum gravity, sociology, and neurobiology.

John Beggs (2023) summarises the situation:

Over the last few decades, an idea called the critical brain hypothesis has been helping neuroscientists understand how the human brain operates as an information-processing powerhouse. It posits that the brain is always teetering between two phases, or modes, of activity: a random phase, where it is mostly inactive, and an ordered phase, where it is overactive and on the verge of a seizure. The hypothesis predicts that between these phases, at a sweet spot known as the critical point, the brain has a perfect balance of variety and structure and can produce the most complex and information-rich activity patterns. This state allows the brain to optimize multiple information processing tasks, from carrying out computations to transmitting and storing information, all at the same time.

The same sense of a critical brain being “just right” also explains why other tasks should be optimized. For example, consider information storage, which is driven by the activation of groups of neurons called assemblies. In a subcritical network, the connections are so weak that very few neurons are coupled together, so only a few small assemblies can form. In a supercritical network, the connections are so strong that almost all neurons are coupled together, which allows only one large assembly. In a critical network, the connections are strong enough for many moderately sized groups of neurons to couple, yet weak enough to prevent them from all coalescing into one giant assembly. This balance leads to the largest number of stable assemblies, maximizing information storage.

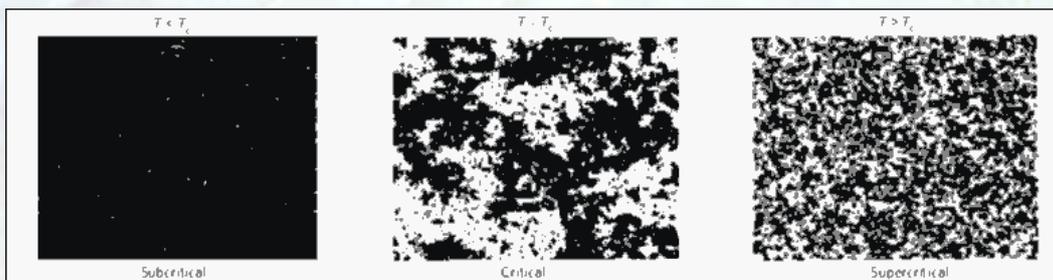

Fig 99e: **Complex is critical.** Three snapshots of the spin configurations at one moment in time for three temperatures (subcritical, critical and supercritical) from numerical simulations of the two-dimensional Ising model. Only at the critical temperature do systems exhibiting a second-order phase transition show the highly heterogeneous correlated domains seen, whereas both sub- and supercritical conditions result in homogeneous states (Shriki et al. 2013).

And this is not just theory or simulation: Experiments both on isolated networks of neurons and in intact brains have upheld many of these predictions (Shew et al. 2009, 2011). Further, we have seen these benefits arise across many different species, in turtles (Shew et al. 2015), cats (Hahn et al. 2010) and even humans (Shraki et al. 2013). Most of these studies have focused on the outer part of the brain, known as the cortex, although some have included subcortical regions as well. Overall, the studies have shown that these networks operate near the critical point.

Similarly, when humans are sleep deprived, their brains become supercritical, although a good night's sleep can move them back toward the critical point. It thus appears that brains naturally incline themselves (Chialvo 2010) to operate near (Ma et al. 2019) the critical point (Beggs 2019,2023), perhaps just as the body keeps blood pressure, temperature and heart rate in a healthy range despite changes to the environment.

Shraki et al. (2013) used MEG to model self organised critical cascades:

Our results demonstrate that normal cortical activity in healthy human subjects at rest organizes as neuronal avalanches and is well described by a critical branching process. Theory and experiment have shown that such critical, scale-free dynamics optimize information processing. Therefore, our findings imply that the human brain attains an optimal dynamical regime for information processing.

The **edge of chaos** is a transition space between order and disorder that is hypothesised to exist within a wide variety of systems. This transition zone is a region of bounded instability that engenders a constant dynamic interplay between order and disorder. We have seen two examples in neurodynamics, firstly in [figure 35\(rt\)](#) where edge of chaos is cited to have higher Lempel-Ziv complexity at the edge of chaos than the normal waking state or coma and seizure, which lie on the ordered and chaotic sides of the edge peak, and secondly in [figure 78\(1\)](#), where Freeman's dynamics of olfaction involves a sniff resulting in high energy chaos whose energy falls on exhalation to either enter an existing attractor representing a known smell, or causes a bifurcation to form a new attractor. Here the edge of chaos is tuned in time, with the chaotic phase ensuring the dynamic doesn't get stuck in a rut of order, followed by descent into lower energy chaos strange attractor, representing the solution, in a similar manner to the thermodynamic annealing and slow cooling in [Hopfield nets](#) to get a sub-optimal stochastic solution to potential landscape minimisations.

Devaney's three **Axioms of Deterministic Chaos**, which apply to both discrete and continuous non-linear dynamics:

- (1) **Butterfly effect:** Sensitive dependence on initial conditions
- (2) **Periodic points dense** and hence repelling, and/or a single dense orbit.
- (3) **Topological transitivity:** Mixing of small open neighbourhoods.

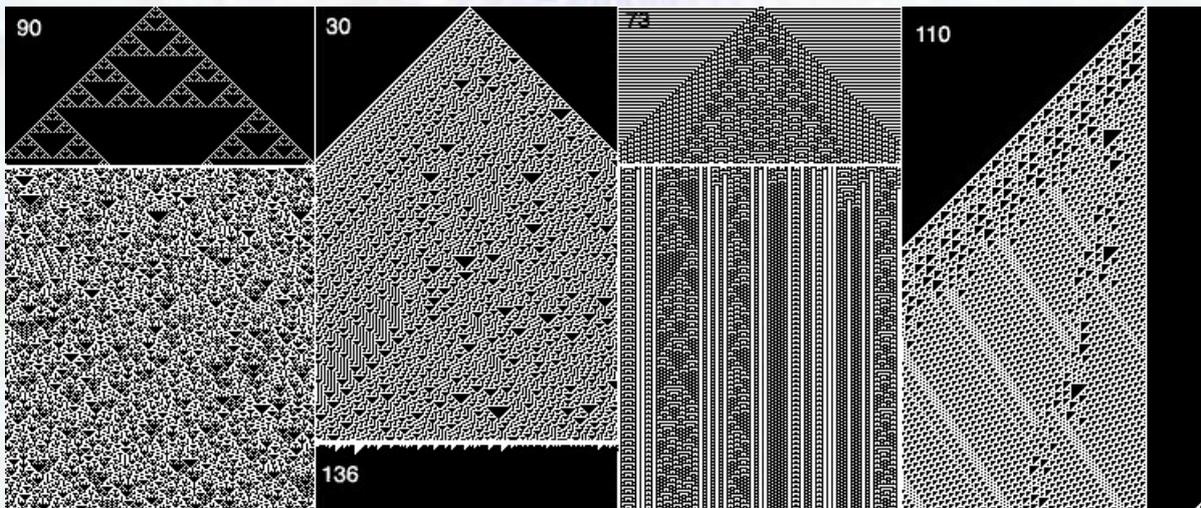

Fig99f: Examples of elementary 1-D 2-state CAs based on triplet of cells, include four types in Wolfram's classification: (1) Eventually fixed (136 = 10001000) (2) Periodic, often as a result of finite separated regions (73=01001001) (3) Chaotic with aperiodic patterns (30 = 00011110) and (4) Complex system potentially capable of universal computation (110 = 01101110). Rule 90=01011010 also has root significance. In each time step all values are replaced by the exclusive or **XOR** of the two neighbouring values.

But there is a beautiful example in the most elementary discrete cellular automata of all – 1D 2 state 3 cell automata that Stephen Wolfram made the centrepiece of "A New Kind of Science". What is outstanding is that not only is rule 30 chaotic and has proved to satisfy all 3 axioms above, but rule 110 which is a Turing complete universal computer is also

formally at the edge of chaos because it contains chaotic subsystems. It is impossible not to look at the 1-D cellular automata without realising that if universal computation arises at the edge of chaos and not in the regime of order there is no hope for any claim to an order based regime of ultimate good in a universe of intelligent systems. This doesn't mean life is bad or cursed by evil because we exist through this centre of the cyclone called the incarnate mortal coil, but since we can't take it with us when we go we need to respect the lives that follow in the best of all possible worlds called REALITY in the flesh. This is the ethic of collective immortality that brings us all together as one. The ethic of cosmology's chaotic edge.

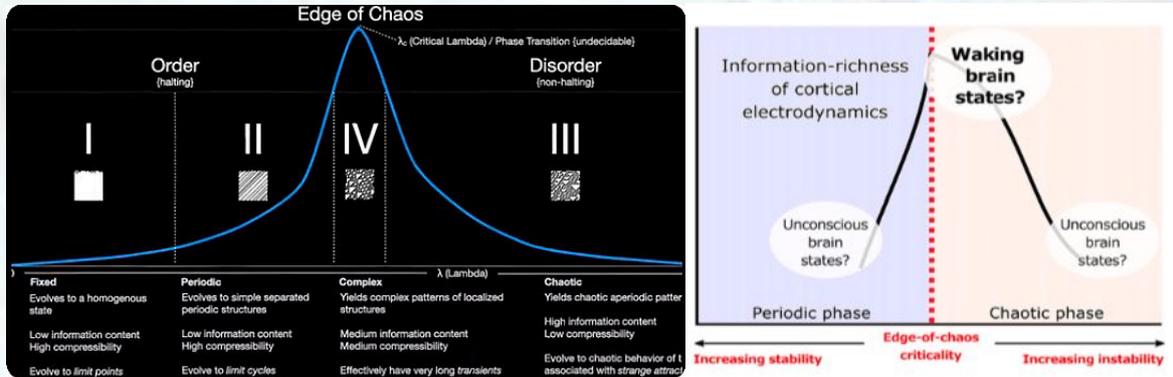

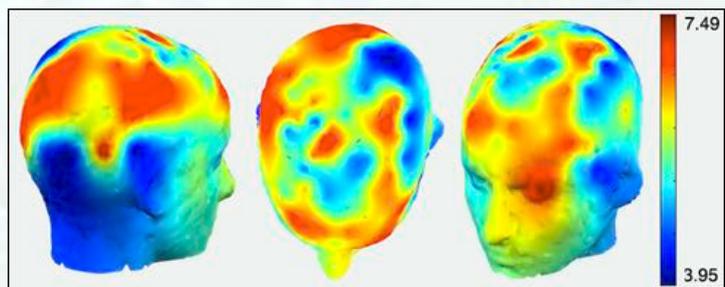

Fig 99g: **Left:** Wolfram's four classes of automata: **Rule 136** is class I, **rule 73** is II **Rule 30** is III and is proven chaotic in the full sense of Devaney (Cattaneo, G et al. 2000). According to Devaney's three axioms of dynamic chaos, Rule 30 displays (1) **sensitive dependence on initial conditions** (two initial configurations that differ only in a small number of cells rapidly diverge), (2) its **periodic configurations are dense** in the space of all configurations, according to the Cantor topology on the space of configurations (there is a periodic configuration with any finite pattern of cells), and (3) it is **topologically transitive**, or mixing open sets (for any two finite patterns of cells, there is a configuration containing one pattern that eventually leads to a configuration containing the other pattern). **Rule 110 IV is an edge-of-chaos universal computer** i.e. Turing complete, as suggested by Stephen Wolfram and proved by Mathew Cook (2004). It also stands at the edge of chaos, in the sense that there exist subsystems on which this rule is chaotic in the sense of Devaney (Chen et al. 2012). **Right:** Toker's (2022) classification of brain states – see fig 35 (right).

Also pivotal to the understanding of edge of chaos is the prisoners' dilemma, where defection is pitted against cooperation and in which the temptation to defect is at the source of social and religious and moral notions of mutual jeopardy and evil. Protest is essential in free societies to avoid tyranny including tyranny of the majority, but the other side is violent criminality, so there is no effective way to mount a universal ethic, except at the edge of chaos. Life exists at the edge of chaos as a far from equilibrium system dependent on chemical gradients and solar radiation.

A variety of complex and chaotic signals show the signature of $1/f$ noise. "Noise" here is regarded as any stochastic, chaotic, or complex signal that has varying power across frequency scales. White noise has the same intensity at all frequencies and each state is independent of the last. The integral of white noise becomes the drunkards walk of Brownian motion. Successive states are heavily dependent on the past states and distribute with frequency as $1/f^2$. Pink, or $1/f$ noise, which is a half integral, is at the sweet balance between history and novelty. Music for example is regarded to commonly be $1/f$ in both the frequency and amplitude domains. Related forms of brain analysis, such as multiscale entropy also form a similar fractal measure of complexity in signal "noise". The correlation dimension, closely related to the fractal dimension on the multifractal spectrum (Schroeder 1992), also provides an estimate of fractal complexity of dynamical strange attractors and the 0-1 chaos test a view of chaotic and edge of chaos neurodynamics (Toker et al. 2020).

Fig 99h: Correlation dimension of resting state eyes closed on caffeine for 20,000 samples over 20 secs. On the same data, the 0-1 chaos test gave a uniform cortical chaos level with mean 0.992 & sd 0.005.

Panpsychism and its Critics

This perspective naturally leads towards panpsychism, the idea that the fundamental constituents of the universe –i.e. quanta – have both a subjective existence and objective behaviour, just as they have both a wave and particle aspect physically. We can't see this

subjective existence or "isness" directly, just as we have difficulty seeing one another's consciousness directly, so objective behaviour becomes the default core description. However we know that the quantum wave function shapes where each particle ends up in a way which remains unpredictable for a single quantum and only becomes determined in the average, in terms of the probability (amplitude squared) of the wave function. This individual idiosyncrasy of a single quantum, when viewed as a particle within its wave function could be interpreted as its free will, as its location in the probability space modulated by the wave function amplitude is completely arbitrary and unbiased, just as it is able to have a determined position in the pilot wave theory if the Feynman implications of particle creation and annihilation are ignored. Likewise one could interpret its consciousness as its integrated "awareness" of the universal quantum entanglement through its wave function. One could thus conclude that the consciousness of the observer is apperceptive of the free-will of the quantum particle, since we are not asserting that the observer is applying their will to determine that Schrödinger's cat is alive or dead, but simply that our subjective consciousness is perceiving it to be in one of the two states. In either case we are dealing with what appears to be subjectively conscious observation of a quantum displaying psychic behaviour exerting an equivalent of volitional will masked by irreducible randomness.

Panpsychism doesn't just apply to any physical object such as a spoon (Goff 2019, Seth 2021a), where there is no manifest form of active behaviour one can associate with the object. It can be associated with single quanta, where idiosyncratic quantum uncertain behaviour is manifest. Panpsychism might also be associated with other adventitious quantum events such as evolutionary mutation, and might also become manifest in edge of chaos quantum processes in the open environment where chaos can lead to further entanglements (Chaudhury et al. 2009, Steck 2009), which are not subject to the suppression of chaos noted in closed quantum systems. Evolution is particularly sensitive because adventitious mutations form a chain of idiosyncratic single collapses in sequence, in which no convergence to the probability interpretation actually takes place.

We have already seen in Chris Koch's description of IIT his use and then rejection of panpsychism as a basis to introduce integrated information systems as an alternative, however Symbiotic Existential Cosmology makes a similar analysis of diverse natural systems extending beyond those of living animals that is consistent with a unique form of panpsychism that does not have the problems cited by Chris Koch, or Anil Seth.

A succinct account of the emergence of subjective consciousness from quantum panpsychism, consists of individual quanta, edge-of-chaos processes with quantum sensitivity due to the butterfly effect, biogenesis, and prokaryotes, becoming emergent eucaryote cells and organisms. I shall associate consciousness as such only with a discrete transition to coherent excitability of single cells with the eucaryote endosymbiosis and the evolution of this into the coordinated excitability of organismic nervous systems, in a clear-cut biological model of subjective consciousness. This dispatches Seth's "combination problem" – how to combine small conscious entities such as quanta into larger ones, mischaracterised as a problem of panpsychism's own making, because the types of coordination are a product of physical neuro-dynamic processes forming boundary conditions upon the complementary subjective conscious aspect.

Anil Seth, in "Being You" (2021b) provides a provocative account of the "exhilarating new science of consciousness". When asked if we will ever fully understand consciousness, and if we do what will that mean for our understanding of ourselves and our place in the world, he says:

"It's a very good question, but it's a hypothetical situation. The reason I am hesitating is that some people who are new to the idea of scientifically explaining conscious feel threatened by it. ... This attitude is especially true when you come to topics such as free will. People say "But no, I decided what I want to do", thus claiming this is a residue of the age-old belief in human exceptionalism that we are at the centre of the universe and distinct from all the other creatures. "Having got rid of those exceptionalist ideas, I think that the picture of the universe is infinitely richer, more beautiful, more rewarding." (Dixon 2022).

However this is incorrect, as Darwin's view was that free will spanned the metazoans "down to the polype". There is thus simply no connection between human exceptionalism and free will and it leads to an incorrect claim that a true understanding of consciousness suggests that free will is an illusion. He nevertheless has an insightful view of the evolutionary basis of consciousness within nature with which I agree:

We're going through this transition where we will begin to understand consciousness as part of the wider tapestry of nature. "Now that is threatening if you're still hanging on to your experience of being you as something apart from nature, separate from it. But I think that's exactly the way Copernicus and Darwin were ultimately incredibly enriching. It will be and it already is incredibly enriching to understand consciousness within the wider patterns of the universe and the natural world (Dixon 2022).

But Copernicus is here conflated with Darwin when the extended view of subjective consciousness as a privileged view appears to be cosmologically accurate as a climax conscious phenomenon providing precisely this privileged view and what he is saying is that the analytical view of objective science has revealed nature's true and confounding detail to the exclusion of subjective experience. While it may be true of religious cosmologies such as the Sabbatical Creation and Heaven and Hell, this view of the exclusive primacy of objective empiricism is fundamentally incorrect.

Seth cites Thomas Nagel as a basis for his naturalistic materialism, who in "What's it like to be a Bat" (1974) contended that while humans could never experience what a bat experiences, there would nevertheless be something it was like for the bat to be a bat, thus invoking subjective phenomenology as part of the discourse on consciousness.

However in this he cites the brain as a "complex prediction machine rather than a mere computer". This is insightful because it recognises the key function of consciousness shared by all animals to predict existential threats and sources of opportunistic hunting, feeding and sex through environmental prediction which is an established neurophysiological fact. But it is still exploring animal conscious as an implicitly mechanistic phenomenon, which he extends to three key areas: Levels of consciousness, the content of consciousness and the self.

This then tallies with his research approach, to set aside the hard problem of why subjective consciousness exists at all, if a prediction machine can do it well or better, to the easier problems relating brain functionality to states of mind through experimental neuroscience. According to his "real problem of consciousness" the primary goals of consciousness science are to explain, predict and control the phenomenological properties of conscious experience. In short, addressing the real problem requires explaining why a particular pattern of brain activity, or other physical process, maps to a particular kind of conscious experience, not merely establishing that it does.

This is something well established in neuroscience, as much of the research on psychedelic states reviewed in this work attests for one of the most complex and difficult of these states to assess. However, correspondence between brain states and conscious states do not explain whether the brain states cause the conscious states and in particular do not come anywhere close to empirically concluding that conscious volition, or free will, are merely subjective delusions of causal function of a prediction machine.

This approach leads to a series of mantras such as "I predict therefore I am", implying that conscious mental states are just controlled hallucinations (Seth 2018) to predict circumstances and are thus not real and that the self is just a construct having no intrinsic or even volitional meaning or value. Yes we know conscious experience is also an internal model of reality constructed by the brain to make sense of the world, but it is although an evolved model, a superbly veridical model enhancing reality, which outside is an indecipherable flux of photons, atoms, electrons and other quanta having no phenomenal characteristics apart from mass, wavelength and/or position and energy and/or time.

These hallucinogenic conclusions simply don't follow and stylistically devalue veridical experience and create a mystique of consciousness research as successfully unravelling the subjective foundations of our existential condition in favour of an occluded, albeit sophisticated mechanism. In the absence of solving the hard problem, this is a dangerous appeal to promissory materialism which diminishes and invalidates the human experience of natural reality, we depend on to survive as a species.

Anil Seth (2021a), in critiquing panpsychism, advances the case that the success of materialistic science is based on explanation, prediction, and control (EPC), the criteria by which many scientific enterprises are assessed, thus reducing biological 'vitalism' in a demystifying dissolution into molecular biology. Goff has countered that some scientific advances such as Darwin's theory of evolution "*emerged from a dramatic insight, rather than incremental dissolution*". But the objection to EPC is fundamental, because, at the very climax of biology, neuroscience has currently no idea of how to solve the hard problem or how the easy problems might be combined to evoke consciousness either. Goff argues that quantitative science does not capture qualitative properties characteristic of subjective qualia. The intrinsic difficulty with Seth's "real" problem of consciousness – how to distinguish different types of qualia e.g. red and blue sneakers, is that it completely fails to address the root question of subjectivity, which is by nature entirely different from the localisable, analysable, distinguishable and separable properties of objective reality and arises in both quantum observation in physics and the hard problem in neuroscience in complementary ways. The cosmology deals with this by accepting root primitive subjectivity, then expanded into sentient attentive consciousness with the eucaryote endo-symbiosis, which then becomes a tightly-coupled society of neurons subjected to boundary filter

conditions imposed by cerebral neurodynamics to provide adaptive context. Thus subjectivity is intrinsic, while the details of qualia are imposed by the boundary conditions described by empirical neuroscience.

But Seth's final criticism is that "Worst of all for panpsychism is that it is not itself testable, and that it does not lead to testable predictions". The problem is not about testability as such but how to make a test in a subjective regime that is by definition not objectively observable by others except by their demeanour and behaviour. This claim shows an inability to determine appropriate criteria for subjective testability. Legal decisions do not just depend on circumstantial (physical) evidence, but on sworn conscious testimony of a veridical nature. While this may be difficult for a single photon because it can only report from its behavioural trajectory, it is certainly possible and accepted scientifically at the high end of the scale in human subjective reports, each of which counts as a statistically verifiable data point. And by the mutual affirmation test invoked by the cosmology. However the details of just what the ultimate nature of conscious experience is in the cosmology of mental states illustrated in [fig 107](#) is as yet not fully characterised, not least due to legislation against psychedelics.

This problem is significant. Albert (1992 82-3) in the context of consciousness collapsing the wave function from imprecision about what consciousness actually is:

How the physical state of a certain system evolves (on this proposal) depends on whether or not that system is conscious; and so in order to know precisely how things physically behave, we need to know precisely what is conscious and what isn't.

We have also discovered that quantum entanglement between particles is both critical and universal to how the universe works. In special relativistic quantum theories, wave functions are coupled in both directions in time, with advanced and retarded solutions providing handshaking between future absorbers and past emitters (King 1989). This is evidenced in the Wheeler delayed choice experiment, [fig 74](#), confirmed by communication between satellites in Earth orbit (Vedovato et al. 2017). Even in a one quantum wave function, the particle can be detected only once in its wave function whether it occurs at earlier or later times, so collapse of the wave function has to occur simultaneously throughout past, present and future space-time, as suggested by the transactional picture.

In a trend that indicates just how inscrutable the "well" of quantum entanglement between two quantum systems can be, a paper on quantum complexity theory (Ji et al. 2020) shows that it is impossible to calculate the amount of correlation that two quantum systems can display across space when entangled (Castelvecchi 2020). The work concerns a game-theory problem, with a team of two players who are able to coordinate their actions through quantum entanglement, even though they are not allowed to talk to each other. This allows both players to 'win' much more often than they would without quantum entanglement. But the paper concludes that it is intrinsically impossible for the two players to calculate an optimal strategy. This implies that it is impossible to calculate how much coordination they could theoretically achieve. Thus there is no algorithm that is going to tell you what is the maximal violation you can get in quantum mechanics.

The Crack between Subjective Consciousness and Objective Brain Function

In this respect, it is pertinent to quote Popper and Eccles (1984 96) coining of the phrase "promissory materialism":

"the new promissory materialism accepts that, at the present time, materialism is not tenable. But it offers us the promise of a better world, a world in which mental terms will have disappeared from our language, and in which materialism will be victorious. The victory is to come about as follows. With the progress of brain research, the language of the physiologists is likely to penetrate more and more into ordinary language and to change our picture of the universe, including that of common sense. So we shall be talking less and less about experiences, perceptions, thoughts, beliefs, purposes and aims; and more and more about brain processes, about dispositions to behave, and about overt behaviour. In this way, mentalist language will go out of fashion and be used only in historical reports, or metaphorically, or ironically. When this stage has been reached, mentalism will be stone dead, and the problem of mind and its relation to the body will have solved itself."

We thus take the obvious foundational realities of existence – consciousness & volition – upon which we depend for our sanity and survival and turn our empirical experience into a vacuum, ablated in the contrivance that a combination of biological constraints and mechanistic physical laws, which together can be the natural complement of existential consciousness, and instead unravel all the actuality of existence, as a descriptive illusion. We thus tell ourselves an arcane story that existence itself is a just thermodynamic constraint, neutralising our very agency to do anything meaningful, spontaneously imaginative, creatively transformative or merely good as in Bertrand Russell's [dire warning](#).

Conscious: Etym Latin *consciūs* 'knowing with others or in oneself' (from *conscire* 'be privy to') + **-ous**

When we turn to the actual definition of consciousness e.g. in Merriam-Webster we find that essentially ALL the definitions of consciousness are dealing with subjective experience!

Definition of consciousness

1a : The quality or state of being aware **especially of something within oneself.**

1b : The state or fact of **being conscious of** an external object, state, or fact

1c : **Awareness** especially : concern for some social or political cause:

"The organization aims to raise the political consciousness of teenagers."

2 : The state of being characterized by **sensation, emotion, volition, and thought** : mind.

3 : The **totality of conscious states** of an individual.

4 : The **normal state of conscious life.** *"he regained consciousness".*

5 : The **upper level of mental life** of which the person is aware as contrasted with unconscious processes.

Francis Crick and Christof Koch acknowledge in Crick's words that "Consciousness is the major unsolved problem in biology", in his foreword to Koch's (2004) "The Quest for Consciousness". Koch (2018) in "What Is Consciousness?", makes clear in his first sentence that: "Consciousness is everything you experience" thus acknowledging that it is the sum total of subjective experience. Koch makes clear in his discussion that their strategy is rather to define the NCC or neural correlates of consciousness, equivalent to the various easy functional problems of consciousness, deferring the hard problem of exactly what subjective consciousness is until these problems are solved, in the hope they will address the elephant in the room. But correlation is NOT causation, so an NCC doesn't imply the brain is causally closed.

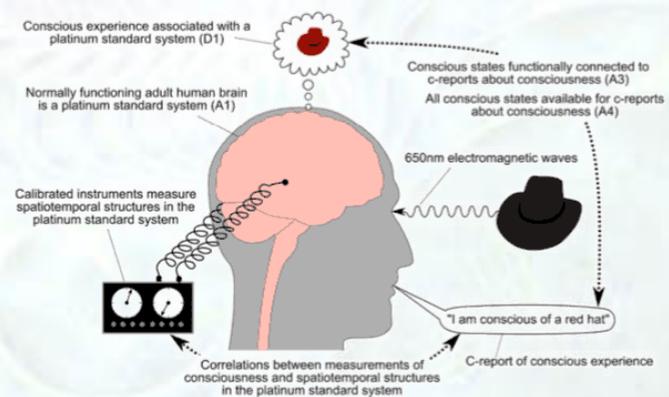

Chris Koch (2020) unveils another defence tactic in discussing the status of near death experiences, admitting physical materialism is just an assumption, but claiming it has a-priori evidential weight requiring "**extraordinary, compelling objective evidence to the contrary**" to overrule it based purely on its past successes in science and technology:

"I accept the reality of these intensely felt experiences. They are as authentic as any other subjective feeling or perception. As a scientist, however, I operate under the hypothesis that all our thoughts, memories, percepts and experiences are an ineluctable consequence of the natural causal powers of our brain rather than of any supernatural ones. That premise has served science and its handmaidens, technology, extremely well over the past few centuries. Unless there is extraordinary, compelling, objective evidence to the contrary, I see no reason to abandon this assumption".

For all Chris's charming romantic approach to reductionism (Koch 2012) this hypothesis underscores the dishonesty of neuroscientific materialism, that he should feel the need to adopt this position, because it places an illegitimate test on reality. We HAVE to assume causal closure, because of the historical success of classical deterministic science in other simpler areas, or a completely unestablished admitted "assumption" is arbitrarily declared to be true under an impossible burden of proof, to establish the contrary – a specific causal violation, which we know to be concealed in the edge of chaos dynamics correlated with the subjectively conscious condition.

How then does neuroscience turn the tables on this central signature of subjective existence, to claim it is exclusively a functional aspect of brain processing, however plausible it might seem, knowing we are biological beings with brains?

Fig 100: The subjectively conscious individual is reduced to a set of functional interactions monitored by calibrated instruments (Gamez 2014), in which the case report "I am conscious of a red hat" is reduced to an objective sentence thereby side-stepping the entire subjective nature of consciousness, in this case a-priori, without even citing any kind of brain process to support it.

Gamez (2014) in "The measurement of consciousness: a framework for the scientific study of consciousness" makes this process clear by defining a set of interlocking definitions which a-priori define it to be so:

D1. **A platinum standard system** is a physical system that is assumed to be associated with consciousness some or all of the time.

A1. The normally functioning adult human brain is a platinum standard system.

A2. The consciousness associated with a platinum standard system **nomologically supervenes on the platinum standard system**. In our current universe physically identical platinum standard systems are associated with identical consciousness. (X is said to supervene on Y if and only if some difference in Y is necessary for any difference in X to be possible.)

A3. During an experiment on the correlates of consciousness, the consciousness associated with a platinum standard system is **functionally connected to its c-reports** about consciousness. (subjective reports)

L1. There is a **functional connection** between consciousness and the [neural]correlates of consciousness.

This series of claims is simply defining consciousness to BE integrated brain function by philosophical supervenience, using the easy problems of consciousness based on simple functionality, as shown in fig 100, where the experimental subject has simply become their functional brain!!

If the brain were simply controlling the process and consciousness was just a marionette being pulled by our brain strings we would experience this as being passive travellers in the passenger seat of intentionality. This is clearly NOT the case, so we need to distinguish brain influence e.g. as a boundary condition shaping, but not fully determining outcomes, from the brain determining conscious states entirely. We need to acknowledge subjective consciousness is the puppet master of edge-of-chaos instability and certainly not conclude that the brain drives the boat of subjective consciousness in a causally determined manner. This is consistent with the view of the brain as a functional filter on consciousness that is participatory with subjective awareness in shaping the nature of conscious experience.

Note that, by citing psychedelics, I am also invoking a paradoxical objective biochemical role for inducing unconstrained subjectivity, so this is a deep cosmological paradox we all need to take careful account of.

A Cosmological Comparison with Chalmers' Conscious Mind

In espousing his philosophical view of naturalistic dualism David Chalmers' central points in "The Conscious Mind" (1996) are as follows:

1. *In our world, there are conscious experiences [which are irreducible to physical descriptions because subjectivity is categorically irreducible to any combination of functional inferences about the objective physical universe and/or the brain].*
2. *There is a logically possible [zombie] world physically identical to ours, in which the positive facts about consciousness in our world do not hold.*
3. *Therefore, facts about consciousness are further facts about our world, over and above the physical facts.*
4. *So materialism is false.*

Rather than a philosophical view based on astute argument, I will take a complementary view of reality, embracing empirical observation for the objective physical aspect and empirical experience for the subjectively conscious volitional aspect. This means that empiricism carries direct evidential weight over logical discourse while preserving the empirical and theoretical basis of scientific inquiry and the veridical nature of existential experience.

In regard to the above, support 1, 4 and 3 (for other reasons), but remain unconvinced about 2. This is because "logically possible" is a philosophical conclusion that lacks an empirical basis in nature. Given a broad acceptance of 1 on the basis that the subjective phenomena are categorically different from any possible explanation in objective terms it remains unclear that a universe without conscious experience can become manifest as all our knowledge of the physical universe is gained through conscious experience of it. Nor is it empirically evident that such a "zombie" universe could display identical properties with living ecosystems if it did, since such a condition is unachievable.

David then takes a very cautious view, retreating to the very brink of materialism by asserting that consciousness is naturally supervenient to the physical, although not logically so, noting that this does not invoke Cartesian dualism:

So it remains plausible that consciousness supervenes naturally on the physical. It is this view — natural supervenience without logical supervenience — that I will develop. ... The arguments do not lead us to a dualism such as that of Descartes, with a separate realm of mental substance that exerts its own influence on physical processes.

David then effectively asserts, and later explicitly assumes causal closure of the physical universe as a justification, on grounds of personal opinion rather than empirical evidence:

The best evidence of contemporary science tells us that the physical world is more or less causally closed: for every physical event, there is a physical sufficient cause. If so, there is no room for a mental "ghost in the machine" to do any extra causal work. A small

loophole may be opened by the existence of quantum indeterminacy, but I argue later that this probably cannot be exploited to yield a causal role for a nonphysical mind.

I reject this point of view, based on the fact that: (1) quantum reality consists of causal process punctuated by quantum uncertainty and entanglement. (2) This is exacerbated by open system quantum chaos, inducing further entanglements because the kind of edge of chaos phase-coherence processing used by the brain becomes subject to butterfly effect sensitivity at tipping points in conscious processing where critical insights and decisions over uncertain outcomes are resolved. This has also invoked a reappraisal of the exclusiveness of sufficient, rather than final causes, because resolving quantum field problems, e.g. in the Feynman formalism involves implicit information from the future absorbers. Therefore the classical view of efficient causality central to the notion of classical causal closure remains unproven. To wager such a position in advance of scientific verification is a belief not a description of nature.

Chalmers describes his position as a form of property dualism:

The dualism implied here is instead a kind of property dualism: conscious experience involves properties of an individual that are not entailed by the physical properties of that individual, although they may depend lawfully on those properties. Consciousness is a feature of the world over and above the physical features of the world.

The position I am advancing, involving a complementarity between the subjective mind at large and the physical universe could also be described as a form of property dualism, but working in the scientific-existential paradigm, I describe it as asymmetric complementarity, following wave-particle, boson-fermion, and other biological complementarities, such as sperm and ovum. These are not considered to be “property dualistic”, as the complementarity is integral to the natural condition, or cosmological “design” as a whole in the case of cosmological symmetry-breaking.

For a design example, the four core quantum forces of nature display a particular type of broken symmetry ([fig 71](#) lower left), which introduces a fractal design into the universe resulting in biological tissues and brains as climax structural outcomes, without assuming any form of teleology – theistic or anthropic.

Chalmers then advances the “plausibility” of consciousness nevertheless having an [entirely] physical basis, generated by contingent laws of nature such as the biological functionality of brain processing:

It remains plausible, however, that consciousness arises from a physical basis, even though it is not entailed by that basis. The position we are left with is that consciousness arises from a physical substrate in virtue of certain contingent laws of nature, which are not themselves implied by physical laws. This position is implicitly held by many people who think of themselves as materialists. ... Some people will think that the view should count as a version of materialism rather than dualism, because it posits such a strong lawful dependence of the phenomenal facts on the physical facts, and because the physical domain remains autonomous.

I shall reject this view both on multiple grounds: (1) It remains unestablished that quantum cosmology is physically autonomous as a whole or that the universe can become manifest without conscious observers. (2) Volitional autonomy is evidential to the conscious subject but no causal physical process such as a machine displays autonomy as such. (3) It results in a contradictory treatment of the subjective realm where Chalmers asserts that consciousness is irreducible but later, as we shall see, claims the phenomenal can be subtracted from volitional causality over the physical, when volition is manifest consciously as well as in behaviour and Chalmers’ arguments fractures the two, rendering the conscious awareness of volition to be a delusion and the physical manifestation in consciously motivated behaviour to have no causal basis. This is the classical materialist trap!

On the one hand we have the zombie establishing consciousness phenomena are categorically independent of the physical and on the other we have a similar argument making them subtractable from the causal, thus invoking a philosophical Catch 22.

Chalmers then indicates he will explore new fundamental properties and laws of consciousness, detailed in a major section of his work. Symbiotic existential cosmology solves this problem differently by associating subjective phenomena as complementary manifestations of physically dynamic properties of brain processing rather than parallel laws in their own right. I reserve my position on this claim because it invokes a type of analysis successful in the exploration of the physical world, because fermionic matter is granular because of the Pauli exclusion principle, leading to the fractal material complexity of matter and hence biology. It is unclear such a “subjectively reductionistic”

approach can be successful in the subjective realm, as subjectivity is not clearly subdividable in the same way, as is expressed as a noted feature of Eastern philosophy:

To bring consciousness within the scope of a fundamental theory, we need to introduce new fundamental properties and laws.

Chalmers cites physicist Steven Weinberg looking towards an explanatory chain from fundamental laws:

*In his book *Dreams of a Final Theory* (1992), physicist Steven Weinberg notes that what makes a fundamental theory in physics special is that it leads to an explanatory chain all the way up, ultimately explaining everything. But he is forced to concede that such a theory may not explain consciousness. At best, he says, we can explain the "objective correlates" of consciousness. "That may not be an explanation of consciousness, but it will be pretty close"*

Chalmers then cites two possible outcomes, citing proto-phenomenal properties in passing as a possible option:

There are two ways this might go. Perhaps we might take experience itself as a fundamental feature of the world, alongside space-time, spin, charge, and the like. That is, certain phenomenal properties will have to be taken as basic properties. Alternatively, perhaps there is some other class of novel fundamental properties from which phenomenal properties are derived. Previous arguments have shown that these cannot be physical properties, but perhaps they are nonphysical properties of a new variety, on which phenomenal properties are logically supervenient. We could call these properties protophenomenal. Most of the time, however, I will speak as if the fundamental properties are themselves phenomenal.

This leads to seeking a parallel with the elegance of physical laws. I would question this approach, as the subjective is so fundamentally different from the objective that modelling subjective phenomena on the success of physical laws invokes a subjective reductionism even if not through proto-phenomenal or proto-panpsychic means:

The case of physics tells us that fundamental laws are typically simple and elegant; we should expect the same of the fundamental laws in a theory of consciousness. ... To capture the spirit of the view I advocate, I call it naturalistic dualism. It is naturalistic because it posits that everything is a consequence of a network of basic properties and laws, and because it is compatible with all the results of contemporary science.

He notes that this could rather be what one might rather call dual-aspect monism, citing matter and energy as alternatives, but not the complementary wave-particle aspects of quanta. This is problematic because matter and energy are not complementary but functionally equivalent, for example in terms of $E = mc^2$:

I should also note that although I call the view a variety of dualism, it is possible that it could turn out to be a kind of monism. Perhaps the physical and the phenomenal will turn out to be two different aspects of a single encompassing kind, in something like the way that matter and energy turn out to be two aspects of a single kind.

In dealing with possible objections to his approach, Chalmers cites emergence as a foil while still involving materialism, noting however that it has to exceed the usual limits, for example on biologically emergent properties. I agree with Chalmers on this:

Sometimes it is argued that consciousness might be an emergent property, in a sense that is still compatible with materialism. In recent work on complex systems and artificial life, it is often held that emergent properties are unpredictable from low-level properties, but that they are physical all the same. ... If consciousness is an emergent property, it is emergent in a much stronger sense. There is a stronger notion of emergence, used by the British emergentists (e.g., Broad [1925]), according to which emergent properties are not even predictable from the entire ensemble of low-level physical facts. It is reasonable to say (as the British emergentists did) that conscious experience is emergent in this sense.

I agree with Chalmers rather than his description of Searle's position although I admire Searle's work ⁴⁵:

Like me, Searle (1992) holds that consciousness is merely naturally supervenient on the physical. He allows that a zombie replica is logically possible, holding that consciousness is merely caused by states of the brain. But he denies that this is a variety of dualism, even property dualism. This might seem to be a mere terminological issue, but Searle insists that the ontological status of consciousness is the same as that of physical features such as liquidity, so the issue is not merely terminological.

⁴⁵ Beginning with a spirited discussion of what's wrong with the philosophy of mind, Searle (1992) characterizes and refutes the philosophical tradition of materialism. But he does not embrace dualism. All these "isms" are mistaken, he insists. Once you start counting types of substance you are on the wrong track, whether you stop at one or two. In four chapters that constitute the heart of his argument, Searle elaborates a theory of consciousness and its relation to our overall scientific world view and to unconscious mental phenomena. He concludes with a criticism of cognitive science and a proposal for an approach to studying the mind that emphasizes the centrality of consciousness to any account of mental functioning.

We now come to the crux of the problem – the relationship between subjective conscious experience, volitional will and causal efficacy over the physical world:

A problem with the view I have advocated is that if consciousness is merely naturally supervenient on the physical, then it seems to lack causal efficacy. The physical world is more or less causally closed, in that for any given physical event, it seems that there is a physical explanation (modulo a small amount of quantum indeterminacy). This implies that there is no room for a nonphysical consciousness to do any independent causal work. It seems to be a mere epiphenomenon, hanging off the engine of physical causation, but making no difference in the physical world.

Chalmers notes two responses to Thomas Huxley's (1874) coining of the term epiphenomenalism, after observing frogs with cranial ablations still managing to jump out of a pool of water: *Huxley (1874) advocated such a view, but many people find it counterintuitive and repugnant.*

Chalmers' two grounds – counterintuitive and repugnant are pejorative of conscious experience and fail to invoke the full scope of the grounds for the invalidation of epiphenomenalism. The fact that something is counterintuitive or repugnant obviously doesn't mean it is not true. Newton's laws of motion were first seen to be counterintuitive, but are true nevertheless in their domain of application. Likewise disease and death are repugnant but universal realities of existence. But that's because incorrect criteria are being used. Neither of them carry the force of veridical affirmation from empirical experience of our volitional actions and decisions which are the "critical point". Epiphenomenalism is invalidated by empirical experience because it fails the mutual affirmation test of subjectively conscious volitional agents. An argument, however astute, doesn't carry the water of conviction against empirical observation, or experience.

It may seem "counterintuitive" or even "pretentiously naive" to trade off mutual affirmation between conscious biological organisms against the assumed physical causality of the entire universe, but this is a valid cosmological position, given the fact that, as far as we know, the physical manifestation of the universe can only be verified by conscious perception of its existence. The alternative to conscious volition is experiential and cosmological catatonia.

Chalmers acknowledges the mysterious nature of causation in rejecting claims of a full formal epiphenomenalism citing the possibility of a breakdown in our classical notions of causality:

In responding to this, I will pursue a two-pronged strategy. First, it is not obvious that mere natural supervenience must imply epiphenomenalism in the strongest sense. It is clear that the picture it produces looks something like epiphenomenalism. Nevertheless, the very nature of causation itself is quite mysterious, and it is possible that when causation is better understood we will be in a position to understand a subtle way in which conscious experience may be causally relevant. ... On the second prong, I will consider the reasons why epiphenomenalism might be found unpalatable, and analyze their force as arguments.

In questioning causality Chalmers first cites Humean causation, upon which all it is for A to cause B is for there to be a uniform regularity between events of type A and events of type B, or a slightly more restrictive form in which any nomic (or lawful) connection suffices. Chalmers see these as inadequate and demurs that many conscious individuals will attribute such correlations to be causes when they may not be. He also fairly rejects overdetermination – the notion that both subjective and objective causes can come to bear in parallel on the same effect or behaviour.

Chalmers acknowledges that there are two classes of facts that do not supervene logically on particular physical facts: facts about consciousness and facts about causation and that these two may be linked:

A third strategy rests with the very nature of causation itself. We saw in Chapter 2 that there are two classes of facts that do not supervene logically on particular physical facts: facts about consciousness and facts about causation. It is natural to speculate that these two failures might be intimately related, and that consciousness and causation have some deep metaphysical tie.

A proposal like this has been developed by Rosenberg (1996), who argues that many of the problems of consciousness are precisely paralleled by problems about causation. He argues that because of these parallels, it may be that experience realizes causation, or some aspects of causation, in the actual world. On this view, causation needs to be realized by something in order to support its many properties, and experience is a natural candidate. If this is so, it may be that it is the very existence of experience that allows for causal relations to exist. Of course, this proposal is extremely speculative, and faces some problems. For a start, it seems to lead to a version of panpsychism the view that everything is conscious, which many find counterintuitive.

This is an extremely important point because the only evidence we have for classical causality is through our conscious experience of the universe in the affairs of the world around us. The laws of physics, both classical and quantum, contain no arrow of time upon which sufficient causes can be based and our only theoretical evidence for it comes

from the stochastically driven second law of thermodynamics, with quantum entanglement having the spooky implications of retrodiction also imputing final causes. It is thus true (1) that the only way the physical universe actually becomes manifest is through our conscious experience of it and (2) that the laws of quantum mechanics lead to superimposed quantum states and the potential for Schrödinger cat paradox multiverses, which our conscious experience may play a key part in resolving. But as Chalmers points out this leads to panpsychism:

There is of course the threat of panpsychism. I am not sure that this is such a bad prospect — if phenomenal properties are fundamental, it is natural to suppose that they might be widespread — but it is not a necessary consequence. ... An alternative is that the relevant properties are protophenomenal properties. Either way, this sort of intimate link suggests a kind of causal role for the phenomenal.

Nevertheless he concedes that his view of natural supervenience feels epiphenomenalistic. However, he then mounts an attempt to marginalise the consequences:

Some people ... may be tempted by an interactionist variety of dualism, in which experience fills causal gaps in physical processes. Giving in to this temptation raises more problems than it solves, however. For a start, it requires a hefty bet on the future of physics, one that does not currently seem at all promising; physical events seem inexorably to be explained in terms of other physical events. It also requires a large wager on the future of cognitive science, as it suggests that the usual kinds of physical/functional models will be insufficient to explain behavior. But the deepest problem is that this view may be no better at getting around the problems with epiphenomenalism than the view with causal closure, for reasons I will discuss shortly [the assumed ability to subtract the phenomenal from the causal].

He then mounts a critique of the ability of the quantum universe to alter the classical causality of brain states, on two key fronts (1) quantum uncertainty and (2) collapse of the wave function:

- (1) *The only form of interactionist dualism that has seemed even remotely tenable in the contemporary picture is one that exploits certain properties of quantum mechanics. There are two ways this might go. First, some have appealed to the existence of quantum indeterminacy a nonphysical consciousness might be responsible for filling the resultant causal gaps, determining which values some physical magnitudes might take within an apparently "probabilistic" distribution (e.g., Eccles 1986). Although these decisions would have only a tiny proximate effect, perhaps nonlinear dynamics could amplify these tiny fluctuations into significant macroscopic effects on behavior. ... This is an audacious and interesting suggestion, but it has a number of problems. First, the theory contradicts the quantum-mechanical postulate that these microscopic "decisions" are entirely random, and in principle it implies that there should be some detectable pattern to them—a testable hypothesis. Second, in order that this theory allows that consciousness does any interesting causal work, it needs to be the case that the behavior produced by these microscopic decisions is somehow different in kind than that produced by most other sets of decisions that might have been made by a purely random process.*
- (2) *A second way in which quantum mechanics bears on the issue of causal closure lies with the fact that in some interpretations of the quantum formalism, consciousness itself plays a vital causal role, being required to bring about the so-called "collapse of the wave-function." This collapse is supposed to occur upon any act of measurement; and in one interpretation, the only way to distinguish a measurement from a non-measurement is via the presence of consciousness. This theory is certainly not universally accepted (for a start, it presupposes that consciousness is not itself physical, surely contrary to the views of most physicists), and I do not accept it myself, but in any case it seems that the kind of causal work consciousness performs here is quite different from the kind required for consciousness to play a role in directing behavior. It is unclear how a collapse in external perceived objects allows consciousness to affect physical processing within the brain; such theories are usually silent on what happens to the brain during collapse. And even if consciousness somehow manages to collapse the brain state, then all the above remarks about apparently random processes and their connection with behavior still apply.*

Both these questions are extensively addressed in this chapter of the monograph. There is no empirical evidence that brain processes are causally closed. Shepherd (2017) points out, that the neuroscientific threat to free will has not been causally established, particularly in the light of Schurger et al. (2012, 2015), also [discussed herein](#). It is illegitimate to assume that any connectedness between subjective and objective in quantum uncertainty would result in gross or even detectable variations from pseudo-randomness, particularly if the relationship is one complementary to the physical universe as a whole. We already know that, in the absence of wave function collapse third party quanta do invoke compounded entanglements.

Chalmers then begins to explore the futility of invoking spooky quantum pseudo-particle states or subjective "psychons", as these don't in themselves demonstrate experiential properties:

Imagine (with Eccles) that "psychons" in the nonphysical mind push around physical processes in the brain, and that psychons are the seat of experience. We can tell a story about the causal relations between psychons and physical processes, and a story about the causal dynamics among psychons, without ever invoking the fact that psychons have phenomenal properties.

This brings us to the nub of Chalmers' critique, with which I disagree on empirical grounds:

Any view that takes consciousness seriously will at least have to face up to a limited form of epiphenomenalism. The very fact that experience can be coherently subtracted from any causal account implies that experience is superfluous in the explanation of behavior, whether or not it has some subtle causal relevance.

I see this conclusion as the core of a dilemma all forms of philosophical causal reasoning apply to conscious volition in particular. It is evident that core physical theories defining the laws of nature, from Newton's laws of motion to cosmological TOEs, or theories of everything, are not explicitly about causality, but the description of nature through symmetries, symmetry-breaking and equational relationships that successfully define characteristics of nature we can empirically observe and confirm, such as the doubling of the bending of light around the Sun due to the Sun's gravitational field, confirming Einstein's theory of general relativity.

To make a claim on logical grounds that the subjective "phenomenal" aspect can be subtracted from the causal is not a valid comment about the status of subjective experience but the particular way the philosophical discourse is treating causality. Science is a product of theoretical predictions and confirming empirical observations. Neither is the theory a cause of the observations but a natural description of the circumstances predisposing to them. It is thus empirical observation that is the standard of validating natural science and it is the same standard of empirical experience that defines the natural investigation of the subjective domain. In this regard, the standard is and has to be veridical affirmation by empirical experience, not a logically astute argument to the contrary in defiance of subjective evidence.

Chalmers then repeats his mischaracterisation as the common objection: *The most common objection to epiphenomenalism is simply that it is counterintuitive or even "repugnant." Finding a conclusion counterintuitive or repugnant is not sufficient reason to reject the conclusion, however, especially if it is the conclusion of a strong argument.*

In my view this is an incorrect portrayal of the central existentially experienced objection, which is that our conscious existential experience is centrally and unambiguously that of being an intentional agent acting in the physical world to further our physical survival and social success. We do this by a coherent integrated experience of responding to circumstances over which we have partial control, focusing our attention and volitional will of making decisions and carrying out ensuing physical actions with purposive intent, consciously aware of our intentions and the strength of our wilful determination, in exactly the same way we process and pay attention to our sensory experience.

We are thus aware and aware that we are aware, and aware that we intend and aware that we are aware that we intend and aware that we are aware that we act wilfully, intentionally and often decisively and tenaciously resist attempts by other agents and the vagaries of the world at large to impede our autonomy as conscious volitional living beings functioning as physically causal agents. To characterise the inconsistency between this view of organismic conscious existential survival in the natural world as merely because the unverified claim of epiphenomenalism is counterintuitive on the one hand is to attribute it to a failure of astuteness and on the grounds of repugnance on the other hand to a failure of our wishful emotions to recognise the stark limitations of our sense of autonomous survival against the odds. This amounts to a philosophical misrepresentation of the realities.

Human perception is described as veridical because it evokes an experience of the world around us that is more true to reality than the incoming sensory information. Our perception of our volition is likewise veridical, to give us a truthful expression of the way our conscious attentive will is securing our survival in real time. To concede sensory perception is veridical and to deny it entirely for our perception of our volition is a contradiction – in Gilbert Ryle's stark terminology – a category error. If epiphenomenalism were actually, in any qualitative, or even quantitative respect true, our veridical perception would inform us that we are mere passengers accompanying our action without any veridical sense of our volition.

Chalmers then goes into the counter-objections in detail:

More detailed objections to epiphenomenalism fall into three classes: those concerning the relationship of experience to ordinary behavior, those concerning the relationship of experience to judgments about experience, and those concerning the overall picture of the world that it gives rise to.

The first is an attempt at finesse. Chalmers demurs on veridical volition because he attributes it to mistaken regularity or an indirect nomic (lawful) connection, ultimately attempting to dispense with it as merely an intuition which cannot have the force of an astute philosophical argument:

We are much more directly aware of experience and of behavior than we are of an underlying brain state; upon exposure to systematic regularities between experience and behavior, it is natural that a strong causal connection should be inferred. Even if the connection were only an indirect nomic connection due to relations to the underlying brain state, we would still expect the inference to be made. So this intuition can be explained away. In any case, this sort of objection cannot be fatal to the view, as it is an intuition that does not extend directly into an argument. It is an instance of the merely counterintuitive.

The second however he concedes is both worrying and potentially fatal. My position is that it is manifestly fatal, because, Chalmers concedes it is incompatible with our knowledge of experience, as I have already discussed:

The second class of objections is more worrying. It seems very strange that our experiences should be irrelevant to the explanation of why we talk about experiences, for instance, or perhaps even to our internal judgments about experiences; this seems much stranger than the mere irrelevance of my pain to the explanation of my hand's withdrawal. ... Some claim that this sort of problem is not merely counterintuitive but fatal. For example, it might be claimed that this is incompatible with our knowledge of experience, or with our ability to refer to experiences. I believe that when these arguments are spelled out they do not ultimately gain their conclusion, but these questions are certainly challenging.

As noted the basis of my objection is that Chalmers' resort to the use of astute causal argument, while dismissing veridical awareness of volition in action as intuitive by comparison with robust philosophical argument is fatal because argument is a symbolic expression of a very narrow subset of subjective experience and can't pretend to account for it as a whole. But the core objection is that this violates the principles of verification by empirical experience that are the foundation of the "scientific" exploration of the subjective.

Chalmers is ever astute and acknowledges that some people, including myself will find his position to be a fatal flaw:

I do not describe my view as epiphenomenalism. The question of the causal relevance of experience remains open, and a more detailed theory of both causation and of experience will be required before the issue can be settled. But the view implies at least a weak form of epiphenomenalism. Some will find that nevertheless the epiphenomenalist nature of this position is a fatal flaw. I have some sympathy with this position, which can be seen as an expression of the paradox of consciousness: when it comes to consciousness, it can seem that all the alternatives are bad. However, I think the problems with all other views are fatal in a much stronger way than the counterintuitiveness of this one.

Summarising his position he states his four key assumptions:

The argument for my view is an inference from roughly four premises:

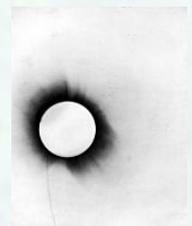

1. *Conscious experience exists.*
2. *Conscious experience is not logically supervenient on the physical.*
3. *If there are phenomena that are not logically supervenient on the physical facts, then materialism is false.*
4. *The physical domain is causally closed.*

Chalmers finally states his naturalistic dualism succinctly:

Then there is my view, which accepts premises (1), (2), (3), and (4): vii. Naturalistic dualism. Consciousness supervenes naturally on the physical, without supervening logically or "metaphysically."

My position is to deny (4) on the basis of the veridical nature of empirical experience and volition, which is both inconsistent with causal closure of the physical. This is so because verification between subjectively conscious agents depends on mutual veridical affirmation of their common status as volitional conscious agents, just as replication by empirical observation is pivotal to objective science. This is what all sane human beings, not subverted by implicit belief in materialism assert, consistent with conscious observation of the universe being necessary and integral to the ability to establish and hence manifest its existence.

Fig 101: One of Arthur Eddington's photographs of the 1919 solar eclipse experiment, confirming the time taken was double, consistent with relativity in single experienced image presented in his 1920 paper announcing its success (Dyson, Eddington & Davidson 1920, Earman & Glymour 1980, Coles 2019).

To subsume veridical experience of volition to refutation by philosophical argument, on the basis that phenomena can be subtracted from causality and hence that volition can be discounted as merely "intuition" rather than empirical experience, is as fallacious as attempting to mount a philosophical argument that the doubling of the bending of light around the Sun due to the Sun's gravitational field does not mean that we should accept relativity because the general field equation $G_{\mu\nu} = \Lambda g_{\mu\nu} + \kappa T_{\mu\nu}$ is simply a numerical expression describing a functional relationship and not a causal statement,

especially having conceded that: “*there are two classes of facts that do not supervene logically on particular physical facts: facts about consciousness and facts about causation*”.

And Chalmers has one very astute final observation:

There is also an eighth common view, which is generally underspecified: viii. Don't-have-a-clue materialism. "I don't have a clue about consciousness. It seems utterly mysterious to me. But it must be physical, as materialism must be true." Such a view is held widely, but rarely in print (although see Fodor 1992).

Ultimately we come back to his persistent, and as detailed in my view, incorrect contention that the phenomenal component can be subtracted from the causal, when the issue is that volition is both experientially phenomenal and physically efficacious as we know experientially, and thus can't validly be subtracted from the phenomenal aspect:

The deepest reason to reject options (iv) and (vi) is that they ultimately suffer from the same problem as a more standard physics: the phenomenal component can be coherently subtracted from the causal component.

It should be noted that Chalmers does seriously acknowledge the potential relevance of panpsychism as a possible solution, as I have:

Personally, I am much more confident of naturalistic dualism than I am of panpsychism. The latter issue seems to be very much open. But I hope to have said enough to show that we ought to take the possibility of some sort of panpsychism seriously; there seem to be no knockdown arguments against the view, and there are various positive reasons why one might embrace it.

In “The Meta Problem of Consciousness” Chalmers (2018) discusses the meta-problem of explaining why we think consciousness poses a hard problem, or in other terms, the problem of explaining why we think consciousness is hard to explain. In this he addresses phenomenal reports: the things we say about consciousness (that is, about phenomenal consciousness). Problem reports are a fact of human behaviour. Because of this, the meta-problem of explaining them is strictly speaking one of the easy problems of consciousness. Chalmers contrasts *illusionism*: the view that consciousness is or involves a sort of introspective illusion, while realists think conscious experiences are real direct phenomena. Chalmers notes that because illusionism is held by a minority, it makes sense to understand the problem as the meta-problem and focus on solving it.

This invokes a research program involving (i) experimental philosophy and psychology, linguistics, and anthropology studying subjects' judgments about consciousness, (ii) work in psychology and neuroscience on the mechanisms that underlie our self-models and bring about problem reports and other phenomenal reports, (iii) work in artificial intelligence and computational cognitive science on computational models of phenomenal reports, yielding computational systems that produce reports like ours, and (iv) philosophical assessment of potential mechanisms, including how well they match up with and explain philosophical judgments about consciousness.

Chalmers is principally targeting a complementary problem to the hard problem which can help elucidate these dichotomies, but it applies more generally in the sense that it concedes the role of subjective reports and poses questions of how these can be rationalised in philosophy and particularly in neuroscience, where subjective experience and subjective reports tend to take second tier to hard physical data on brain states in so far as they can unambiguously be elucidated in conscious subjects.

Chalmers uses this approach to discuss theories of consciousness such as IIT Tononi & Koch (2015) that integrated information is the basis of consciousness, noting that there is no obvious link between integration of information and these judgments. Since, according to IIT, for every system with high integrated information there will be a computationally isomorphic simulated system with zero integrated information. He applies the same challenge to global workspace theories (Baars, 1997), where the basis of consciousness is a global workspace that makes information available to other systems in the brain. How does the global workspace help to explain our judgments about consciousness? Again, it is not obvious how the workspace explains problem reports involving a sense that consciousness is puzzling.

Higher-order thought theories (Rosenthal, 2002) say that conscious states are those that are the objects of higher-order thoughts. But again it is not clear how mere higher-order thoughts explain why we report mental states as being conscious nor how higher-order thoughts explain why we report conscious states as puzzling.

He notes that it can apply to quantum theories (Hameroff and Penrose, 1996; Stapp, 1993) that say there is a strong tie between wave-function collapse and consciousness. Does wave-function collapse play a central role in explaining reports of consciousness? One might worry that the answer is no, since wave-function collapse only selects one of multiple branches of the wave function. If a subject says 'I am conscious' in the selected branch, it is arguable that the subject also says 'I am conscious' in many unselected branches. If so it looks as if there may be an explanation of the reports which is prior to wave-function collapse.

The challenge also applies to panpsychist theories which hold that human consciousness is some sort of combination of micro-consciousnesses in fundamental entities. The combination problem for panpsychism is to explain how micro-consciousnesses can combine to yield our consciousness, now extended to explain how these combination states play a central role in bringing about reports of consciousness.

In considering introspective models which attribute primitive relations to qualities and contents, Chalmers, notes that introspection is especially central to Graziano's (2013) AST model in which 'awareness is a model of attention' and doubts attention is the right choice for the complex relation that is being modelled, suggesting instead that it is more generally a model of representation.

Chalmers' own view with which I have complete agreement is best quoted for its sheer lucidity:

My own tentative view is that the most promising solution to the meta-problem lies in primitive relation attribution and the sense of acquaintance: our experiences seem to primitively acquaint us with qualities in the environment, and these experiences are themselves objects of acquaintance. I favour a realist theory of consciousness where consciousness does in fact involve acquaintance in this way. This line tends to suggest a combination of a first-order representational view of consciousness (consciousness involves immediate awareness of worldly properties) with a self-representational view of consciousness (consciousness involves immediate awareness of itself). I do not think this sort of awareness is reducible to brain mechanisms, but one might expect some sort of corresponding structure at the level of brain mechanisms.

Uziel Awret (private communication) notes the need to distinguish the ground of subjectivity from the properties:

"The intransitive properties of consciousness those common to all conscious states, systems and creatures like some rudimentary 'there is something it is like' to be such systems, or to be in such states, and are usually referred to as 'phenomenal character' (some would add privacy and intentionality). The transitive properties of consciousness are those that distinguish between different conscious states like blue and red or a square and a triangle and referred to as 'representational content'. Conscious mental states have both structural and non-structural properties including aspects of the representational content that are more structural lending themselves to scientific investigation and non-structural aspects of phenomenal character that seem less accessible to scientific investigation.

The question - What is it about consciousness that is made necessary by the way the brain is? Should be broken in two:

- 1) *What is it about the structural properties of consciousness that are necessitated by the way the brain is?*
- 2) *What is it about phenomenal character that is necessitated by the way the brain is?*

In symbiotic existential cosmology I am focusing only on phenomenal properties as intractable to the hard problem, the Darwinian panpsychism likewise refers only to primitive subjectivity in general with an evolutionary model, where consciousness as we know it, is an emergent property induced by the eucaryote endosymbiosis when the membrane became freed for informational excitability and social signalling via neurotransmitters. The transitive structural properties have to be seen in the context of how the brain operates neurodynamically.

Consistent with his view in "The Conscious Mind", Chalmers and McQueen (2021) have philosophically explored a variety of scenarios in which consciousness could collapse the wave function in realistic circumstances, dealing specifically with the paradoxes arising from superposition of the observer as a quantum system. They explore various options including super-selection rules forcing the elimination of some components of the superimposed state and super-resistance models in which a threshold causes collapse. Chalmers and McQueen adopt IIT as a basis for their analysis, but this introduces abstractions, in which consciousness is associated with a discrete Markov formulation consistent with observed features of conscious existence but not possessing subjectivity as such. This leads to a description where we are really analysing features of consciousness in objective brain dynamics rather than subjective experience to establish causality.

Summarising the difference between Chalmers & McQueen's approach and Symbiotic Existential Cosmology, we compare four philosophical objections they cited and addressed:

(a) What is a superposed state of consciousness? Chalmers & McQueen are stating a functional IIT model of "consciousness", so they state such a situation is possible, in conflict with our veridical experiences. The symbiotic cosmology concurs with the veridical conclusions of subjective conscious, and with Wigner's position that this is "absurd", although it doesn't rule out bodies and brains being quantum objects.

(b) How do quantum effects make a difference to macroscopic brain processes? Chalmers & McQueen do not assume quantum sensitivity in the "warm" brain, stating that "*we have treated brain states as superpositions of numerous decoherent eigenstates, which themselves may involve relatively classical processing in neurons*". Symbiotic cosmology accepts the need for brain states to have at least some quantum sensitivity and presents evidence for this. Critically it does not require the kind of isolation that current quantum computing methods do, by either isolating themselves from any significant decoherence, or by adiabatic quantum computing at very low temperatures following a series of zero energy configurations. All it requires in symbiotic cosmology are critically poised cellular states that become sensitive to individual quantum fluctuations in critically poised ion channels, initially in individual eucaryote single celled organisms. Later this process can become coupled in animal brains, through critically-poised whole brain states as coherent "excitons" distinguishable from one another through phase coherence discrimination being sensitive to threshold transitions in single neurons and their ion channels.

(c) What about macroscopic superpositions? Chalmers & McQueen hedge their bets, firstly suggesting machines might also be conscious: "*For a start, if a correct theory of consciousness associates these devices with some amount of consciousness (as may be the case for IIT), then the devices will collapse wave functions much as humans do.*" Then following it with a catch-all: "*Even if these devices are not conscious, it is likely that typical measuring devices will be entangled with humans and other conscious systems, so that they will typically be in a collapsed state too.*"

(d) What about the first appearance of consciousness in the universe? This is a problem for their particular models. They seek to solve this with an approximate super-resistance model: "*For eons, the universe can persist in a wholly unconscious superposed state without any collapses. At some point, a physical correlate of consciousness may emerge in some branch of the wave function, yielding a superposition of consciousness and unconsciousness (or their physical correlates) with low amplitude for consciousness*".

The symbiotic cosmological model is panpsychic so the subjective element is included from the cosmic origin. Indeed it would then be possible for the universe to be involved in collapse of its own wave functions and develop a course of history, without human observers, which is a key strength of the theory, but in the case of the experimental quantum measurements of the types we are dealing with in the cat paradox, there is a specific interaction between human organismic consciousness and the experiment, so collapse could be evoked by the human observer's consciousness. This may apply more to (a) situations in how the brain performs its own phase front coherence processing between wave voltages and discrete action potentials and (b) in unstable tipping points in prisoners' dilemma paradoxes in open environment situations, in which there are real or potential threats to survival, as in fig 91.

Penrose (2014) suggested a similar process involving gravitationally induced collapse, in which a quantum state remains in superposition until the difference of space-time curvature attains a significant level. However all quantum entanglement experiments on Earth take place successfully in an environment where gravitation is present.

Chalmers also notes that their general view might prove causal closure of consciousness: "*The same might apply to the connection between consciousness and non-conscious processes in the brain: when superposed non-conscious processes threaten to affect consciousness, there will be some sort of selection. In this way, there is a causal role for consciousness in the physical world*" (Chalmers 2003, pp.262-3). This is very close to Stapp's proposal above and the approach adopted in this cosmology, and to neuroscience notions of peripheral rather than coherent conscious processing in the brain, but it is being applied to collapse of the brain as a quantum superimposed state, not the subjective mind.

While this is provocative of an attempt to confirm a causal basis for volitional will, the difficulty here is that quantum observation depends on the subjective experience of the observer, not just integrated brain states we might accept as being the objective correlates of subjectivity, so the explanation of the theory is led into dealing with potential paradoxes of physical collapse that are tied to objective brain states rather than subjective experience, which is the veridical reality generating the unique history of the universe, rather than superimposed multiverses. In the author's view Albert's critique is pivotal – human society remains impeded from exploring the actual nature of unconstrained

conscious states and only with the full exploration of these and collecting veridical accounts of visionary states can we begin to assess the nature and cosmological status of subjectivity.

To coin an analogy from the mathematical world, integral transforms such as the Fourier transform convert localisable time-amplitude information into frequency information, creating a mapping from all states into a complementary configuration space. If the subjective basis of experience is a transform of the entire physical universe under the encapsulated constraints of the organismic brain, it may have a form of predictive power without possessing any localisable or separable features of the objective universe. Effectively it would be sampling the entire scope of quantum entanglement throughout the universe and throughout space-time, and through the consciousness of other sentient organisms, echoing Huxley's notion of organismic consciousness being a filter upon the "mind at large". Brain processing already appears to use transforms as integral to its wave processing, so the analogy is highly pertinent.

In later interviews, Chalmers (2022) has a much more positive view of the potentiality for subjective consciousness to causally interact upon the physical brain, through collapse of the wave function:

The next radical conclusion is that consciousness is separate from the physical world but it also has an effect on the physical world – a causal impact. We need to be cautious here, but science hasn't taught us that physics is a closed system – that the brain is a closed system. There's one route there that I think might be worth pursuing. A hole that's left open for where consciousness can have some impact. In quantum physics, most of the time, the wave function follows the Schrödinger wave equation, but every once in a while a strange thing happens – it collapses – why does the wave function collapse? Quantum mechanics doesn't tell us – it just says it collapses when a measurement occurs. What's a measurement? No one knows. On the face of it what looks like a measurement is a measurement by a conscious observer. If you wanted to have consciousness to effect physics, it looks like physics could not be designed more perfectly.

Moreover, in regard to the collapse of the wave function, the idiosyncrasy of single quantum instances displays unmitigated liberty, except in the context of repeated measurements of the same kind, in which the probability distribution is normalised by its asymptotic approach to the wave function real power $\phi \cdot \bar{\phi}$, in which the empirical wave function is an integral representation of entanglement at large. In the biological context no such repeated measurements occur so there is a close correspondence between quantum idiosyncrasy, the unpredictability of brain states at unstable tipping points and the uncertain and unpredictable nature of open environment survival crises. As non-IID (independent and identically distributed measurement) quantum processes do not necessarily converge to the classical, the need to prove the case for subjective interaction is no stronger than the need for materialism to prove its case for causal closure, which remains non-evident empirically.

Autopoiesis and Neurophenomenology

The term autopoiesis refers to a system capable of producing and maintaining itself by creating its own parts (Maturana & Varela 1991) to define the self-maintaining chemistry of living cells.

An autopoietic machine is a machine organized (defined as a unity) as a network of processes of production (transformation and destruction) of components which: (i) through their interactions and transformations continuously regenerate and realize the network of processes (relations) that produced them; and (ii) constitute it (the machine) as a concrete unity in space in which they (the components) exist by specifying the topological domain of its realization as such a network.

The aim is to give a formal meaning to biological agency as self-organising system, but applied to the cell such self-organisation is largely homeostatic, applying less to advanced organisms, where the hard problem of the explanatory gap and the creative demands of conscious intelligence require more than homeostatic prolongation of cellular life.

To address this, Francisco Varela's (1996) neurophenomenology is an attempt to marry cognitive science with a disciplined approach to experience i.e. phenomenology (Husserl 1913) and thus consists of naturalising phenomenology, as integrated into an explanatory framework admitted by the natural sciences.

Pinholt (2012) notes that Varela's article is written with David Chalmers' 'hard problem' in mind, and functions as an alternative to Chalmers' suggestions of what is needed to solve the hard problem, it is therefore also a step towards a possible solution to the 'hard problem'. Varela agrees with Chalmers that experience is not a candidate for (reductive) eliminativism. But he disagrees with Chalmers that in order for us to solve the gap between cognitive science and experience we need to find some theoretical principles that will do the job. Varela believes that there could be a "neurophenomenological" circulation i.e. a co-determination of both accounts – a joint investigation of phenomena

involving subjective experience, where the phenomenological analysis will be responsible for mapping out the structure of experience from a first-personal perspective, while cognitive science will be responsible for finding the neurological correlates for that experience, of course this approach pre-supposes that there are such things as neurological correlates.

A consequence of this approach is that both have equal status, that each constrain the other in which phenomenological analysis will provide a model or explanation of the structure of experience, while the neuroscientist will, guided by the phenomenological data, attempt to map out the neurocorrelates. According to Lutz and Thompson (2003) neurophenomenology is guided by the proposal that the best current candidate for the neurophysiological basis for consciousness is a "flexible repertoire of dynamic large-scale neural assemblies that transiently link multiple brain regions and areas."

Tim Bayne (2004) has made critiques of neurophenomenology where he remains skeptical towards claims put forward by neurophenomenologists, especially the claim that phenomenology provides a more reliable methodology than other first-person methodologies, including introspection. He reaches the conclusion that neurophenomenologists suggest that neurophenomenology involves more than just neuroscience and phenomenology but doubts the reality of this extension: "Exactly what the something more is, I think, an open question. Varela speaks of changing the "entire framework within which the [hard problem] is discussed". The idea seems to be that neurophenomenology solves the hard problem by undermining the assumptions that generate it."

The problem neurophenomenology shares with autopoiesis is that there is no clear interaction between subjective and objective realities that allows for conscious creativity, insight, innovation and intentional behaviour that characterises both the explanatory gap and the existential condition.

Minimalist Physicalism and Scale Free Consciousness

Fields, Glazebrook & Levin (2021) take a very different approach from naturalistic dualism, they call Minimalist Physicalism MP, which bypasses classical physicalism and seeks to incorporate consciousness as a type of observer-world relationship based only on principles of quantum information that is claimed on empirical grounds to be scale-free and then regards basal systems which they describe as running all the way down the evolutionary tree not just to single-celled eucaryotes and Symbiotic Existential Cosmology does of consciousness proper, but to the first prokaryote and in principal to abstract quantum systems, thus equating with the primitive subjectivity of SEC.

Here, we provide a straightforward construction of fundamental, scale-free features of consciousness and cognition within a generic description of system-environment information exchange as bipartite physical interaction. We term this description "minimal physicalism" (MP) as it makes no assumptions about classical computational architecture, in particular, no assumptions about network architecture, and no physical assumptions beyond those of quantum information theory.

A well-established literature extends the concepts of consciousness — the capability of having phenomenal experiences, however basic or minimally structured—and cognition to phylogenetically basal systems, including free-living or facultatively communal unicells, whether pro- or eukaryotic, plants, and a neural or lower (than mammals, birds, or cephalopods) complexity neural metazoa, particularly flat- worms.

Like the extension of these concepts from humans to nonhuman mammals and then to big-brained non-mammals, this extension to more basal organisms was initially motivated by observations of communication, learning, and behavioral flexibility, and by functional similarities between the mechanisms supporting information processing and learning in basal systems and in more complex systems such as mammals. Both molecular and bioelectric mechanisms of cellular information processing, memory, communication, and error correction are, in particular, evolutionarily ancient and conserved across phylogeny.

Like the Solms-Friston model of the conscious brain, this utilises Markov blankets which form a statistical thermodynamic interface across the cell membrane:

As the locus of molecular, thermodynamic, and bioelectric exchange with the environment, the cell membrane implements a Markov Blanket (MB) that renders its interior conditionally independent of its exterior; this allows the cell to be described as a Bayesian active inference system. The utility of this Bayesian approach has been demonstrated in simulation models of cell-cell communication driving morphogenesis.

The information that transits the cell membrane, and is thereby encoded on the MB implemented by the membrane, is actionable or meaningful to the cell: it "makes a difference" to what the cell does. When the cell's interaction with its environment is represented

as measurement, what renders the information meaningful becomes clear: meaning requires measurement with respect to some reference frame. Viewed abstractly, a reference frame is a value, or more generally a vector, from which deviation is detectable.

This notion of consciousness is an interactive “consciousness of” rather than subjective consciousness as a cosmological complement to the physical universe and in that sense claims to be able to pose the hard problem for example in single cellular prokaryotic systems where the feedback processes can all be identified. I have some reservations about whether this is actually testing the hard problem in its original sense or not. Prokaryote membranes are dominated by respiratory or photosynthetic free energy production, unlike eucaryote membranes which are available for perception and social signalling.

These cross-scale similarities motivate a hypothesis that consciousness and cognition are scale-free phenomena that characterize all living systems. If consciousness and cognition are scale-free phenomena, we can expect them to be supported by common, scalable mechanisms that can be investigated in whatever systems permit the most straightforward theoretical and experimental approaches. Phylogenetically basal organisms, in vitro preparations, and synthetic constructs provide obvious advantages of manipulability and environmental control. Studies of basal systems are, moreover, especially effective in overcoming the intuitions that give rise to the hard problem, as they allow the mechanisms via which single cells and relatively simple multicellular organisms navigate their environments— mechanisms that they share with most of our cells, and with us as organisms— to be investigated in detail.

I nevertheless think the approach is potentially powerful and deeply informative:

Our interest here has not been ontological, but rather empirical: to derive as much as possible from the simple assumption that consciousness involves information exchange subject to the constraints of quantum information theory. We have shown that the MP framework that follows from this assumption allows many of the key features of consciousness to be understood as simple, scale-independent consequences of thermodynamics.

It has led to a description of neurons as hierarchies of quantum reference frames (Fields, Glazebrook & Levin 2022). And has also led to intriguing conclusions on the limits of metabolic limits on classical information processing by biological cells, implying quantum processing in the cell interior (Fields & Levin 2021):

Biological information processing is generally assumed to be classical. Measured cellular energy budgets of both prokaryotes and eukaryotes, however, fall orders of magnitude short of the power required to maintain classical states of protein conformation and localization at the Å, fs scales predicted by single-molecule decoherence calculations and assumed by classical molecular dynamics models. We suggest that decoherence is limited to the immediate surroundings of the cell membrane and of inter-compartmental boundaries within the cell, and that bulk cellular biochemistry implements quantum information processing.

Defence of the real world from the Case Against Reality

I have said that while consciousness is primary, the universe is necessary. Thus we know the universe only through our conscious experiences of it, but its stability and structure is necessary for the existence of conscious life.

Don Hoffman in “The Case Against Reality” (2020) makes the evolutionary case that perception is not veridical in the sense of optimally truthful, but evolved by natural selection:

The classic argument is that those of our ancestors who saw more accurately had a competitive advantage over those who saw less accurately and thus were more likely to pass on their genes that coded for those more accurate perceptions, so after thousands of generations we can be quite confident that we’re the offspring of those who saw accurately, and so we see accurately. That sounds very plausible. But I think it is utterly false. It misunderstands the fundamental fact about evolution, which is that it’s about fitness functions—mathematical functions that describe how well a given strategy achieves the goals of survival and reproduction.

We’ve been shaped to have perceptions that keep us alive, so we have to take them seriously. If I see something that I think of as a snake, I don’t pick it up. If I see a train, I don’t step in front of it. I’ve evolved these symbols to keep me alive, so I have to take them seriously. But it’s a logical flaw to think that if we have to take it seriously, we also have to take it literally. ...Snakes and trains, like the particles of physics, have no objective, observer-independent features. The snake I see is a description created by my sensory system to inform me of the fitness consequences of my actions. Evolution shapes acceptable solutions, not optimal ones. A snake is an acceptable solution to the problem of telling me how to act in a situation. My snakes and trains are my mental representations; your snakes and trains are your mental representations.

Yes cat’s eyes are designed to hunt, with low colour specificity and reflecting retinas to hunt at night with those almond shaped pupils, and insect vision may be even more prosaic but although human perception has evolved by natural selection, human selection has been evolving towards the most generalised adaptable attributes because the human niche is strategically omnivorous of reality. Human perception has thus been consciously naturally selected to

be veridical. Visual reality out there is a chaotic jumble of photons that have no colour only wavelength and particulate energy. Human perception has evolved to give us the most socially and environmentally discerning visual theatre of 3-D, size-conserved, seamlessly integrated experience. Yes, consciousness is also a type of internal model of reality constructed by the brain through evolution, but it is a veridical masterpiece and it is not just a model, but an outstanding manifestation of the ground of conscious being in subjective cosmology. There is no better way of looking at so called “physical reality” that we can possibly imagine!

Hoffman’s perspective on existence is very confluent with this cosmology. He supports the primacy of the quantum description over the false classical description of “mainstream” neuroscience and advocates what he calls conscious realism. Here follow an excerpt from an Atlantic interview (Geferter 2016) via Quanta magazine:

My intuition was, there are conscious experiences. I have pains, tastes, smells, all my sensory experiences, moods, emotions and so forth. So I’m just going to say: One part of this consciousness structure is a set of all possible experiences. When I’m having an experience, based on that experience I may want to change what I’m doing. So I need to have a collection of possible actions I can take and a decision strategy that, given my experiences, allows me to change how I’m acting. That’s the basic idea of the whole thing. I have a space X of experiences, a space G of actions, and an algorithm D that lets me choose a new action given my experiences. Then I posited a W for a world, which is also a probability space. Somehow the world affects my perceptions, so there’s a perception map P from the world to my experiences, and when I act, I change the world, so there’s a map A from the space of actions to the world. That’s the entire structure. Six elements. The claim is: This is the structure of consciousness. I put that out there so people have something to shoot at. ... I call it conscious realism: Objective reality is just conscious agents, just points of view. Interestingly, I can take two conscious agents and have them interact, and the mathematical structure of that interaction also satisfies the definition of a conscious agent. The idea that what we’re doing is measuring publicly accessible objects, the idea that objectivity results from the fact that you and I can measure the same object in the exact same situation and get the same results — it’s very clear from quantum mechanics that that idea has to go. Physics tells us that there are no public physical objects. So what’s going on? Here’s how I think about it. I can talk to you about my headache and believe that I am communicating effectively with you, because you’ve had your own headaches.

The same thing is true as apples and the moon and the sun and the universe. Just like you have your own headache, you have your own moon. But I assume it’s relevantly similar to mine. That’s an assumption that could be false, but that’s the source of my communication, and that’s the best we can do in terms of public physical objects and objective science.

Not only are they [neuroscientists] ignoring the progress in fundamental physics, they are often explicit about it. They’ll say openly that quantum physics is not relevant to the aspects of brain function that are causally involved in consciousness. They are certain that it’s got to be classical properties of neural activity, which exist independent of any observers—spiking rates, connection strengths at synapses, perhaps dynamical properties as well. These are all very classical notions under Newtonian physics, where time is absolute and objects exist absolutely. And then [neuroscientists] are mystified as to why they don’t make progress. They don’t avail themselves of the incredible insights and breakthroughs that physics has made. Those insights are out there for us to use, and yet my field says, “We’ll stick with Newton, thank you. We’ll stay 300 years behind in our physics.”

The neuroscientists are saying, “We don’t need to invoke those kind of quantum processes, we don’t need quantum wave functions collapsing inside neurons, we can just use classical physics to describe processes in the brain.” I’m emphasizing the larger lesson of quantum mechanics: Neurons, brains, space ... these are just symbols we use, they’re not real. It’s not that there’s a classical brain that does some quantum magic. It’s that there’s no brain! Quantum mechanics says that classical objects—including brains—don’t exist. So this is a far more radical claim about the nature of reality and does not involve the brain pulling off some tricky quantum computation.

The formal theory of conscious agents I’ve been developing is computationally universal—in that sense, it’s a machine theory. And it’s because the theory is computationally universal that I can get all of cognitive science and neural networks back out of it. Nevertheless, for now I don’t think we are machines—in part because I distinguish between the mathematical representation and the thing being represented. As a conscious realist, I am postulating conscious experiences as ontological primitives, the most basic ingredients of the world. I’m claiming that experiences are the real coin of the realm. The experiences of everyday life—my real feeling of a headache, my real taste of chocolate—that really is the ultimate nature of reality.

But there is another lesson lurking here! The case is not just against veridical perception itself, but the notion of a “real world” that is independent of our perceptions of it, rather than an elusive quantum reality, in which the universe is manifest through our evolved consciousness of it (Mark et al. 2010, Hofmann et al. 2015, Fields et al. 2017, Prakash et al. 2020). The interface theory of perception (ITP) is a filter theory like Huxley’s “Doors of Perception”, of how the brain constructs our internal model of reality.

I agree with the central point that our perception is a conscious construction and we need to understand it as such, because subjective consciousness IS primary, as Don says, but if the real world doesn’t in any sense stably exist then genes aren’t real. Natural selection is not either. The whole evolutionary ball game over billions of years depends on

the stability of the real world quantum universe over these same time scales or we wouldn't even have a fitness function to select naturally towards. When we are dreaming, things do change like that, so we can have some sort of understanding of the implications and how impossible everything would be without the real world being real.

In interview, Hoffmann dismisses the materialist idea that the hard problem can be solved by physicalist versions of the easy problems, and having gained tenure as an expert in perception, sets out to try to formulate a universal theory starting from the subjective consciousness where the field is less crowded with similar unfruitful ideas:

What will happen if we start from the other direction as a purely scientific and rigorous approach. I'm not talking about mysticism or anything like that. I'm talking about can we get a mathematically precise model of consciousness on its own terms? So then we have to put down mathematical structures, not because they're right but so that we're precise. So that we can then find out why we're precisely wrong. Now you start to make predictions you get. dynamics of consciousness. The test will be can you derive quantum physics from it? Can you get quantum field theory out of it? Because at least if you can you have a mathematically precise solution of the mind-body problem starting in the other direction.

But is it really possible to deduce quantum field theory from subjective consciousness, by taking the same objective mathematical modelling that has proven to work in objective systems outside space-time.

Hoffman, Prakash & Prentner (2023) address this question, with a searing critique of theories of consciousness that incorporate assumed and often occluded physical assumptions in physicalist and phenomenistic accounts alike, targeting in particular, the notion of space-time as doomed:

Most scientific theories of consciousness posit physical systems, or functional properties of physical systems. Some propose that these give rise to consciousness; for instance, global workspace, integrated information, and orchestrated objective reduction. Others propose that these give rise to the illusion of consciousness; for instance, illusionism and attention schema. All of the above falsely assume that spacetime physics is fundamental.

But they base their alternative view of conscious agency on two assumptions:

We start with two posits about consciousness: (1) there are conscious experiences; and (2) there are probabilistic relations among conscious experiences. These posits lead us to the notion of a conscious agent.

While (1) is essential, (2) is a pre-emptive regression into Markov chains, sacrificing subjective experience to the same fate as probabilistic degeneracies of the Born interpretation and Friston's free-energy notion of homeostatic agency:

We make this precise in a mathematical theory of conscious agents, whose dynamics are described by Markov chains. We show how (1) agents combine into more complex agents, (2) agents fuse into simpler agents, and (3) qualia fuse to create new qualia.

This leads to a sterile quasi-probabilistic mathematical theory that in no way has the capacity to represent, let alone manifest, subjective experience.

Morris (2023) notes that Hoffman's ideas of the subjective are to say the least expressionist, although they do have a ring of experiential truth, and echo the ideas of Jung's archetypes and Joseph Campbell's masks of the divine:

The alternative theory Hoffman proposes is that conscious entities are fundamental entities that exist beyond spacetime. These entities are us. And we are also avatars of a single conscious entity that Hoffman calls the "conscious aleph infinity agent." We interact with each other via an interface whose format is spacetime. For Hoffman, what's really going on outside of conscious awareness is so complex, involving non-spacetime dimensions numbering in the trillions or quadrillions. Our simple human minds created an ultra-compressed version of reality stripped of details that would break our brains—if we actually thought with our brains, which Hoffman sees no convincing evidence for. Hoffman's math leads him to conclude that we are avatars of a superconscious or arch-conscious agent, that puts us avatars through the paces of an infinite number of experiences, no matter how joyous or horrific, so that the arch-conscious agent can experience everything. Hoffman also warns against overidentifying with our self, because the self is an avatar. "You are not any particular experience. You are the potential in which those experiences arise and disappear. That's what you really are in your essence. You transcend any particular experience because you are that potential."

Consciousness Cosmology and the Quantum: Putting it all Back Together

All purely materialistic descriptions of consciousness fail the manifestation test. Subjective consciousness is primary and incontrovertibly manifest, while physical reality is inferred through it. Thus for an objective description to lay claim to sweep aside the manifest nature of subjective reality is an artifice. It illustrates why attempting to form models of consciousness without addressing the root cosmological status of consciousness itself can frustrate the discovery process. By attempting to form a model which lays claim to the properties of subjective consciousness while denying

its existential status, a root fallacy is created. Yes it then does seem plausible to opt for a form of brain-mind identity over any seemingly implausible notion of externalism (cosmic consciousness interacting with the brain).

That is why I immediately in June 2021 came to the necessity of a cosmology, in which subjective and objective reality are complements within a single whole, exemplified by nature itself as a climax process and elaborate the description in full empirical detail from there. We all start from conscious experience as a universal reality and infer the physical universe and its physical descriptions from our consensus experience of it. Once we accept subjective consciousness as cosmological in 'nature', the very existence of the subjective mind IS cosmological in nature and assumes it's natural place without physical contrivance.

We know that empiricism is established, both by verifiable empirical observation and by affirmative empirical experience and the semantic notion of empiricism arose this way, because it is naturally evoked in the human mind's world view. Hence the proposition that subjective conscious volition has efficacy over the physical universe is a natural immediately verifiable statement of our existential condition, as I consciously write this passage.

The Central Thesis, makes clear that continuous brain waves, like radio waves and lasers constitute entangled quantum states and explains the interaction of subjective consciousness with the physical brain states moving in and out of wave coherence in terms of neurodynamic phase transition at the edge of chaos coupled to a quantum phase transition between entangled states and projectively reduced quantum states, minimising destructive quantum measurement to address uncertain existential crises the organism faces, leading to a unique form of quantum entangled "anticipation".

David Peat (2013) has a good description of these non-local potentialities in relation to living systems at the edge of chaos and non-local forms of entanglement:

[L]ocality has served physics well, which implies that our hypothetical underlying non-local effects must be extremely subtle. So where should we look for them? Supposing that true non-locality is present quite generally in the universe: how would it manifest itself? I suggest that the most promising place to look is in these extraordinarily sensitive non-linear systems that are termed "chaotic". Systems which suffer constant iteration and in which every tiny region is contingent upon all others are known to behave in extremely complicated ways. Their dynamics are characterized by fractal behavior--in which endless levels of detail are found at finer and finer scales. But "chaos" may be a poor term to describe such systems for it is not so much that they are "random", "anarchic", or "orderless" as that they have an extremely complex and subtle order.

These systems are so extraordinarily sensitive that the smallest perturbation has an uncontrollable and unpredictable effect upon their dynamics. These are the ideal systems in which to study non-local effects for their behavior could well be controlled by the global correlation of vanishingly small effects. Attempting to control such systems locally proves useless: on the other hand global, or non-local description and control may be entirely appropriate. The global co-ordination of boundary conditions, for example, could act to guide, in a very general way, the overall form of the system.

Information which is distributed globally as boundary conditions or very delicate non-local perturbations would be hidden within the apparent chaos of a sensitive system. Attention to individual regions of space would not be sufficient to display this non-local influence. What is required is some new, global description of these systems.

A simple image will illustrate this point. Local disturbances propagate through a system and are normally assumed to dissipate themselves, becoming lost in the random fluctuations of the medium. But in a world in which events are correlated non-locally what may appear to be a vanishingly small random fluctuation may in fact be the manifestation of a global order. Extremely small perturbations, when correlated non-locally could, for example, have the effect of initiating an inwardly moving wave of disturbance which then interferes co-operatively and gives rise to a large local disturbance. This is the reversal of what is normally assumed, in which an effect spreads out and is dissipated. I am therefore suggesting that local events in such systems can have a non-local origin. More generally I propose that sensitive dynamical systems may be guided by non-local effects and are best understood using a non-local description. The possibility of non-local control in chaotic and sensitive systems is far-reaching.

There are a wide variety of systems in nature that have the characteristics of "chaos", or rather of complex, non-local order. In such systems rather than causes producing effects of a similar magnitude it may be more a matter of very tiny, but globally coordinated causes having a wide range of global effects. The size of the cause is no longer related to the magnitude of the effect, what is important is the overall form of that cause. Moreover what appear as "random fluctuations" may be highly significant aspects of global behavior. Life forms a particularly important subset of these globally complex systems. It may be valuable to consider its processes from a non-local perspective. Life "rides the wave" and lives on a delicate knife edge between order and chaos. Some form of non-local correlation of dynamics is, I would suggest, characteristic of living systems.

This monograph provides a good understanding of the relationship between conscious and sub- or un-conscious processing that arises from brain dynamics. Conscious brain states consist of global phase angle modulated excitations

that are interacting with more diverse excitations that are phase decoherent to sufficient extent that these processes remain local and don't necessarily participate in the central "theatre" of conscious experience but remain a resource that is able to and will do so if either the global dynamic changes, or the local one becomes more coherent with the global. I see this view as productively useful, as it explains consciousness as a central arena having ready access to subconscious levels of processing. It allows edge-of-chaos dynamics to be phase tuned as well as harmonic oscillations as exemplified in the bat hippocampus (Eliav et al. 2018) and in cortical phase relationships in psychedelic studies (Muthukumaraswamy et al. 2013, Tagliazucchi et al. 2016, Toker et al. 2022).

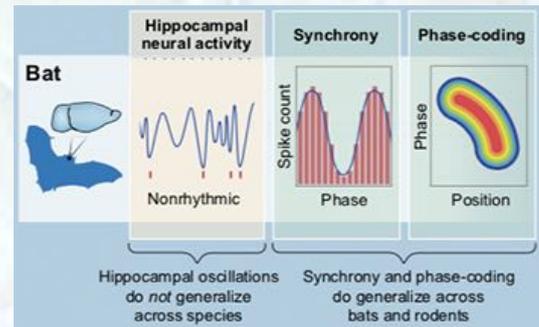

Fig 102: Hippocampal non-rhythmic synchronisation and phase precession (Eliav et al. 2018), see also (Qasim et al. 2021) fig 78(4).

We now come to the scientific description of the super-conscious state, there is obviously a physical dimension to it – if I enter a meditative or entheogenic–contemplative moksha, I can happily understand and describe this neurophysiologically in terms of quietening of the default mode network, and the relinquishing of the subject–environment polarity in favour of a unified state of ego annihilation. I can see it as a natural biophysical state that has become sensitively dependent on the brain's own inner dynamics, in a biologically natural way, by seeing the notion of the cosmic mind as a shared organismic state that emerges only in such dedicated conditions from the biota, meaning that the cosmic mind becomes manifest biologically. I don't need to articulate externalistic physical force fields to achieve this, because subjectivity is already built into the unified cosmology at the root and can fully utilise the known processes of cortical activity as a contextual boundary condition filter to realise qualia neurodynamically.

This kind of complementarity may be akin to a universal integral transform of the state of the entire quantum-entangled universe, or even the AdS/CFT correspondence, so that organismic consciousness is an encapsulated manifestation of the cosmic mind. Such a complementarity doesn't have to be conveyed by hypothetical externalistic constructs to support it, because it is cosmologically complementary to physical force fields.

We can then embark on the other half of the empirical discovery of reality with an open mind and discover for ourselves by mutual empirical experience the inner nature of cosmic reality, without placing outer restrictions upon a discovery process that we can all engage transformatively from within, because, in bringing forth what we have within us – i.e. foundational cosmic consciousness encapsulated in our mammalian biological brains – this can be experienced empirically in a discovery process without a priori theoretical or conceptual preconditions. In summary here is my tentative position about how subjective consciousness interacts with the universe and causality in detail. This is a working hypothesis, not a proven conclusion but I think it has a counter-intuitive twist that may explain everything.

Firstly in quantum mechanics, we have two apparent processes:

- (a) von Neumann type 1: the causality-violating collapse of the wave function on quantum measurement.
- (b) von Neumann type 2: the evolution of the wave function under a Schrödinger wave equation.

There are various versions of QM, from the Everett interpretation where no collapse takes place (but this creates probability multiverses that we don't experience) to Wigner type interpretations where the conscious observer collapses the wave function, to decoherence where collapse results from many interactions. In any event, conscious observers experience Schrödinger's cat either alive or dead in the real world or so it seems, although we do witness superposition in laser light. Napoleon didn't win Waterloo and we experience a line of history taking place partly as a result of our own actions, which I call historicity.

Symbiotic existential cosmology is agnostic about these QM differences, because it imputes primitive subjectivity to quanta, which could then also in principle act as 'observers', but leave this aside and back to the established physics.

When we do a simple two-slit interference experiment one photon at a time, as Feynman marvelled at, the individual photons can end up literally anywhere the wave function amplitude is non-zero throughout space-time. If we make a phase space in which the amplitude is normalised they can literally end up anywhere in this space with equal

probability, just like a random variable. This is the “free-will of the individual quantum, which Conway & Kochen (2009) used to imply conscious free will.

However, when we repeat the experiment multiple times we discover a pattern, that the photographic plate begins to have bands where the photons ended up, varying sinusoidally with the superimposed wave functions. This is an example of IID (independent and identically distributed measurements).

This is how the quantum process converges to the classical in the Born interpretation of large quantum numbers, but it is explicitly violated in both evolution, where each mutation that becomes fixed by selection induces a new context for a subsequent mutation, and in brain dynamics where any quantum event fixed by altering subsequent neuronal activity also changes the context. Again let's leave whether this is possible in the brain aside although I will claim that the butterfly effect, stochastic resonance and global tipping points at critical decisions are ideal ground for this.

Let's look at a single quantum 'instance' again. We have already seen that, in the phase space, the quantum can end up anywhere at all. This is the purest form of free-will we can possibly imagine, except that it is shaped by the wave function, so it has context just like our personal conscious decisions.

What's the flip side of this? It's that the whole process was being guided by the wave function. Now we get to entanglement. In the ideal interference experiment, we have prepared a pristine experiment in which we have defined the wave function simply and precisely by the macroscopic apparatus, but in the real world there are a multitude of third-party interactions, and in the absence of collapse, each of these introduce entanglements that modulate the wave function. In special relativistic quantum mechanics the wave function extends into the future as well as the past when a particle is emitted, as the transactional interpretation shows, so it has entangled “information” about the future which causal computation can't access through local Einsteinian causality, but entangled conscious brain states must have because evolution has conserved this edge-of-chaos consciousness from the eucaryote emergence on.

Indeed in the Everett interpretation all wave functions are part of the universal wave function forming an entangled history from alpha to Omega. So the flip side of quantum free will is the 'consciousness' the wave function possesses globally as a representation of potentially the entire history of reality encoded in the subtleties of the wave function. Thus we have a primitive model of quantum conscious free will.

Now to entanglement in detail. The results of Einstein, Rosen, Podolsky, Bell and Alain Aspect demonstrate that when two particles become entangled in a single wave function and we make independent measurements of both, we find that Bell's theorem is violated, ruling out local Einsteinian causality between the separated particles but consistent with quantum mechanics.

We can do this e.g. with an excited Calcium atom because it has two outer electrons so can transition to the ground state emitting a green and a yellow photon in opposite directions having net zero spin, thus having complementary polarisations. And Aspect did this with time varying analysers which showed that the correlations persisted over space-like intervals that appeared to require local travel between the detectors faster than the speed of light.

The conclusion of the Bell results is that: (a) The polarisation statistics of either photon appears individually random, (b) when we match them up whenever we measure one, the other instantaneously adopts complementary polarisation, but (c) this entangled relationship can't be used to send information between the separated particles.

There is another point here. Both the separate particles look like they are behaving randomly but there is a hidden process going on which is completely masked unless we sample the two together.

Now back to the supposedly causal universe. QM has two interposed processes in causal reality as we experience it: (a) The Hamiltonian progression of the wave function under the Schrödinger equation. (b) The apparently random projection of superpositions onto one of the eigenvectors in collapse.

This is what I call 'punctuated' causality after 'punctuated equilibrium' in evolution. So we now have to ask what is the cosmological source of this randomness? We already know that lots of deterministic processes can end up with pseudorandom or quasi-random distributions. Computers use these to do random simulations and classical deterministic chaotic processes have the property of ergodicity, converging to a space-filling 'thermodynamic' trajectory

characteristic of stochastic systems. So there are a huge swathe of complex processes that could underlie quantum uncertainty that could distribute in the limit to be quasi-random, masking any apparent 'hidden variable theory'.

Now let's go back to supposed causal closure of the universe in the brain context. In the quantum universe, notwithstanding the ebb and flow over Libet's claim, and its later refutations, it is not possible to make any practical empirical experimental test to confirm causal closure of the brain, so the onus on science to demonstrate it fails.

Causal closure might appear to make superficial sense because, unless it IS causally closed, we could have both mind and brain dynamics affecting future brain states, resulting in causal conflict. But if it is confined only to circumstances where the brain dynamics is critically poised in uncertainty, because it is representing an existential crisis where the causally-induced alternatives are finely balanced and the global brain state (in mutual phase coherence feedback with action potentials modulated by stochastic resonance) is at a sensitively dependent unstable tipping point, this corresponds quite closely to a quantum measurement of its own instability.

So we ask this question: "What if the only thing subjective consciousness has the capacity to do is to perform quantum measurements on its on brain's unstable brain states? Does this invoke any form of useful mind-matter interactionism or is it just futile randomness?"

Here I think that it has a huge capacity to be exactly what we are all looking for, because the universe as we know it is paradoxically 'punctuated causality' – literally only half causal and half uncertain in structural terms, so although we don't expect quantum measurement to force any outcomes to cause the cat to be alive rather than dead, it does have a profound effect on the evolution of the universe, turning it from a multiverse into one where Napoleon didn't win the battle of Waterloo, and where Nelson turned his blind eye on the Danish fleet in the Battle of Copenhagen.

Of course some of these events come down to hidden physically causal factors like the positioning of troops or the silly height of the Spanish ships in the Armada's defeat, but the key role of conscious experience, as Michael Graziano's attention schema theory points out, is split-second intuitive life or death decisions, when the shark strikes. We know the brain is also a predictive perceptual computer as shown in the "flash-lag" illusion where it sometimes makes predictive errors, but all this comes down in the end to an intensely conscious split-second real time decision which is going to alter the course of history in exactly the way a quantum measurement does.

Note also that this process emerged in pretty complete form with the founding universal eucaryote ancestor, complete with membrane action potentials, edge of chaos excitability on a global basis, the genes to enable synapse formation and the neurotransmitters as social signalling molecules, and as I noted, the brain is an intimately coupled society of such cells (King 1978, Edwards 2003) operating in essentially the same way.

Human neurons, and by extrapolation neuroglia, are extremely sophisticated human single-celled animals in their own right nurtured by their social environment. If you look at a pyramidal neuron spanning the cortical layers ([fig 122](#)), they are modulated by all the principal neurotransmitters from GABA, through serotonin, nor-adrenaline and even dopamine and the inputs of interneurons as well as fast ionopore receptor fluctuations of NMDA and AMP. Their axonal output is thus an expression of multiple dynamic forces. They are not simply additive Mcculloch-Pitts units and that is why the cerebral neurodynamics is the edge-of-chaos phase tuned dynamic it is.

This means that the brain is conscious at the cellular level and the binding problem is all about how the neuronal and glial excitations are bound together in the overall brain dynamic, which is in phase-coupled feedback between graded cortical potentials in the local EEG and individual action potentials. So we come back to meaning and this means the meaning is in the purview of conscious experience each cell has in its neurosystem context. I see this as a true conscious meaning, but it is a wildly different meaning to the meaning we experience, because neurosystems meaning is a coherently bound dynamics of cellular meaning and the cellular meaning is how the conscious excitability of individual neurons interpret their intimately bound social environment. This is a cellular version of Freeman dynamics and it's very hard for us to make meaning out of it at our coherently bound neurosystems level, but in it lies the solution to the entire dilemma of what consciousness is, the binding problem, and how meaning arises in the multi-celled conscious organism.

Taken to a rather poetic conclusion, we are walking inflated quanta exercising our free will in just the way each individual photon does, except we are doing it in a supremely entangled way that brings the conscious moment into

focus in every detail of our neurodynamic internal model of reality representing the mysterious quantum world around us and the extreme vagaries and computational intractability of the open environment problem, which is worse than the travelling salesman problem because there isn't necessarily only one outcome, but multiple threads, all or any of which may result in annihilation or ultimate survival. You could even speculate that our entire incarnation, from birth to death, is a single quantum measurement, particularly when looked at sideways on in space-time, as the Feynman representation tends to do!

Ram: In your SEC/ICAM, is primal subjectivity fully aware (eternally conscious)? Or is the primal subjectivity in potential form?

Chris: You have contradictory definitions. "Fully aware" is not the same thing as "eternally conscious". No one knows that fully aware humans are "eternally conscious". "Potential form" is completely ambiguous. What does it actually mean? Is primal subjectivity fully aware? That depends on what you mean. A single quantum has a space-time extensive wave function "experiencing" both the past and future in special relativistic quantum reality. One could say this is "aware". It also has a form of volition by projection onto one of its particle eigenfunctions. But that's not what we think of awareness, or volition as.

- (1) If we accept the irreducibility of the hard problem extended to subjective conscious volition over the physical universe, which we can affirm empirically as subjective conscious sentient beings, then subjectivity has to be an integral aspect of matter and hence has a cosmological origin with the universe.
- (2) We have evidence of cellular excitability and neurotransmitters and receptors immediately after the eucaryote endosymbiosis, so we can say the edge of chaos consciousness our neurons and neuroglia possess and hence our excitable brain dynamics arose there.
- (3) Short of that we have only our personal subjective experience as direct evidence and infer other humans and animals are conscious by their vivacious behaviour.

These are the only three observations any of us can make so any deviation from the position of [Symbiotic Existential Cosmology](#) is speculative to specious. That's why [Symbiotic Existential Cosmology](#) is empirically correct and the only possible conscious cosmology consistent with the physical universe.

Ram: Regarding individual human consciousness, my understanding is that it is comprised of conscious subjective experiences (CSEs) of self, exogenous and endogenous stimuli, and conscious components of cognitions such as conscious thoughts from 1pp.

Chris: This is a little difficult to respond to because the way you classify a framework tends to divide it into disjoint categorical objects. So you think conscious experiences are of self, stimuli, and cognitive components. This doesn't work too well for consciousness itself because it can't be subdivided categorically and remain intact and a lot of it is more like watching a movie we have some guidance and control over the outcomes of. For example neither dreams nor visionary experiences are "stimuli" which has a purely external physical connotation I am happier with the "stream of consciousness" as a holistic flow that we both perceive and modulate both emotionally and intentionally. I see cognition and thought as a culturally driven superstructural process that has taken over the conscious brain as a linguistic-based serial process. Thought is really abstractedly talking to ourselves, so it's a highly learned art where we can watch ourselves distractedly reeling out syntactical sequences with semantic meaning and guide them through to a conclusion, just as I am now typing to you, in the same way we can guide a physical sensory process, in our behaviour like hunting with an arrow, or gathering specific plants.

Ram: My first question is: where do these CSEs come from in SEC/ICAM? From what I understand, you assume that all CSEs come from primordial subjectivity, which is complementary to the physical universe. Subjectivity and the universe interact with each other, but I am still having trouble grasping exactly where CSEs originate.

Chris: CSEs in SEC come from encapsulated subjectivity. Encapsulation is a complex physical boundary condition on subjectivity that is both evocative and restrictive. It evokes specific forms of conscious experience and is restrictive in directing conscious experience to environmentally significant situations involving our survival. Our encapsulation is biologically physical. So we have a trichromatic 3D enhanced internal model of physical reality, accompanied by a spectral auditory stream connected to our awareness of elapsing time. We also have complex olfactory experiences and endogenous emotional and physiological senses and veridical perception of our subjective conscious volition over

the physical universe. So we experience and modulate the stream of consciousness while also being able to become engrossed in thought almost to the exclusion of experience itself.

This is all consistent with subjectivity being optimally compliant with these very rich physical boundary conditions to add the essential ingredient of subjective consciousness – that we subjectively experience conscious reality as it unfolds. The place where subjectivity becomes critical is in unstable transitional brain states with no foregone conclusion, where environmental (quantum) uncertainty rules, so there is no determined dynamic or heuristic so subjectivity can act out intuitive interventions on the causal process to jump out of the way of a snake in the grass, where a robot would get struck because it's too complicated to calculate the odds.

We can become entrapped on thought cycles and the ego's desperate struggle for survival so that meditators try to tell us to sit back and be here now or we will become distracted by illusion rather than veridical reality. Thus subjectivity is interacting with the physical universe through subjective conscious volition, some of which is planned and intentional and some of which is deeply intuitive, which is where root consciousness beyond experience itself comes into play.

Ram: My second query is about primordial subjectivity – does it mean a fully conscious psychophysical universe, or is it potentially conscious (i.e., it is not fully conscious, but it has the potential for consciousness)? In Sankhya, it is assumed that CC (cosmic consciousness, Purusha) is fully and eternally conscious at a cosmic level. Is Sankhya's Purusha equivalent to SEC/ICAM's primordial subjectivity at the cosmic level? Or does SEC/ICAM's subjectivity mean potential consciousness (i.e., it has the potential for consciousness, but it is not fully conscious)? For example, does it have the potential for CSE redness? Or is it eternally fully conscious, like Purusha.

Chris: Your classification into "fully" versus "potentially" doesn't capture the phenomenon. I don't accept that a fully fledged cosmic consciousness caused the universe to come into existence. It's a contradiction because consciousness has so many biological attributes and if you strip them all away there is nothing there to make the universe out of. And the cosmology is morally degenerating so its an illusory hopeful monster. Aurobindo tried to talk about conscious aggregates becoming matter but its cheese trying to become chalk or quartz. It's an illusion created by samadhi.

But that doesn't mean cosmic consciousness is just a potential that doesn't exist either. We know we are conscious experiencers and this is a cosmological process because life is the central interactive phenomenon of cosmic symmetry breaking, so cosmic consciousness is also us being conscious here and now, but it's fragmented in each of our separate encapsulations physically, like the fragmented tantric origin. But we can bring about a state of cosmic consciousness through inner states of conscious experience that open the doors of perception so the environmental filters become relaxed so our mind-brain resonates to the cosmic underlying conscious reality rather than immediate survival. Then our physical brains adopt a more cosmic dynamic, which Aurobindo called the supermind for want of a better word.

How the Mind and Brain Influence One Another

To summarise and complete, here is a short discussion with the psychophysicist Stanley Klein:

Stanley Klein: There has been a lot of evidence that mind is being done in the brain. There are indeed a number of folks that think that mind is separate from the brain. Of course the brain is getting input from neurons outside of the brain like from our eyes and ears, etc. I look forward to hearing evidence that points to mind coming from outside of our brain.

Chris: To suggest that mind is outside the brain, if you are a physicalist, means you are asking for the subjective mind to physically exist somewhere outside the brain – i.e. in the toes or round the corner somewhere. You know that's not how it works. Mind is inside and the brain is outside. Both are happening depending on how we choose the discourse i.e. to talk about our experiences, or the physical world we are perceiving.

And Stan, just what is the extensive evidence that mind is being done in the brain? There is no way of escaping that any brain research on a conscious individual mind, is happening when an experimental recording is made of brain dynamics e.g. Freeman dynamics. But this isn't mind being done by the brain – just accompanying brain states associated with conscious activities.

Stan Klein: However, I don't fully understand what you said about the mind-brain connection. Could you provide more details of what you have in mind.

Chris: The trick is in how the brain uses dynamical instability computationally. It's attempting to form a causal model, but the open environment is computationally intractable and indeterminate. The single celled eucaryote learned to use edge of chaos membrane excitation for predictive sentience, by being sensitively dependent on external quantum modes to generate a physical awareness of its environment. As the amoeba-flagellates evolved, they became genetically adapted to take advantage of this predictively, gaining perpetual survival opportunities. I see this as being non-IID at the cellular level so its a genuine quantum process at the edge of chaos that aids survival because the membrane excitation feedback process under genetic control becomes predictive in ways that involve similar situations to weak quantum measurements and expand instantaneous time into a quantum of the present.

In a complex brain, each of the neurons are carrying out an exceedingly complex social version of this, that grew out of neurotransmitters as social signalling molecules, so the social signalling has become a wired form of synaptic signalling driven at high speed through axonic and dendritic connections. The result is a Freeman dynamics brain at the edge of chaos that seamlessly uses a combination of self-organised criticality to resolve uncertainties and making quantum measurements through wave phase coherence of neuronally networked populations. Because it evolved from adaptive unstable cellular consciousness it seamlessly integrates computational and quantum predictive dynamics. We experience this as "the present". This is just a description on the fly of neurodynamics that passes far more sophistication onto the neurons themselves as highly evolved human cells with extreme delicate social connections simultaneously using all the social signalling molecules from glutamate through GABA serotonin and so on. But the key to understanding it is not brain dynamics alone but brain development and the roles the neurons of each neurotransmitter type have in mutually organising the social network of synapses.

Stan: Many thanks for your detailed discussion of many details of how the brain does its thing. You seem to be agreeing with me that the brain is where the action is for producing the mind. As I've said many times, present science doesn't yet fully understand how the brain does it. Do you agree with the above or do you think the brain isn't producing mind.?

Chris: No I don't agree Stan! The brain and mind are producing one another. The brain is not causally closed and the mind is transcausally volitional. By transcausal I mean the result is a product of a transactional process between past and future underlying quantum reality and wave function collapse.

The brain, as a developmentally and dynamically structured set of conscious neurons, is providing a partially open dynamical computational context in which the mind fills in the unstable parts of the quantum dynamic. This is being driven by tightly-coupled cellular sentience on the part of neurons and their complementary neuroglia. This means that, from the mind's point of view, the brain is a boundary condition acting as a filter on the way the mind can volitionally act. That's why we look out at the conscious experiential world we perceive as individuals. By act I do not mean causally interact in the sense of interactional dualism where we can define functional mechanisms on both sides. Nor is it simply dual aspect monism because the complementary processes are very different, with the subjective able to be experienced but neither observed objectively nor decomposed.

The nature of the mind is related to and complementary to the underlying "volitional" process that determines wave function collapse. This means again that mind is complementary to the universe as a whole. We appear to have our own mind, not because there are many minds, but because the many brains impose varying boundary constraints, as encapsulations on the subjective condition.

Stan: Chris, You said: "By transcausal I mean the result is a product of a transactional process between past and future underlying quantum reality and wave function collapse." Why did you include "future"? Present science doesn't allow information to go backwards in time or faster than light. But strangely enough some influences can go faster than light. Wonderfully crazy.

Chris: The Feynman description and transactional interpretation both involve hand-shaking between past and future through the special relativistic wave propagator and offer and confirmation waves. All quantum processes are time reversible. Weak quantum measurement is an averaged out process which involves retrodiction post-hoc. It's still partly IID because of the repeated measurements to establish the 'Bohmian' trajectories. But cellular sentience is a feedback loop at the quantum level that isn't trying to make a classical prediction, just to exert anticipatory volition, escaping the snake strike, so it's basically an inflated version of context dependent wave function collapse, including

advanced influences from absorbers. I'm not being too precise about this because SEC is agnostic as to quantum interpretations.

You are happy with entanglement involving instantaneous definition of the state of the remote particle, when the nearby one has its polarisation measured because this doesn't involve a classical signal exchanged faster than light. It simply reveals a hidden correlation that now has become determinate. But this actually occurs because the advanced waves from both detectors arrive at the source of the entangled photons and the changed result is referred back in the retarded wave to instantaneously define the remote particle's orientation. So that is the way it all works.

Real positive energy determines the arrow of time and the direction of classical causality, but collapse of the wave function punctuates this. So if you are talking about real positive energy particles, forward causality is true, but if you are talking about collapse of the wave function it isn't. For example virtual particles don't conserve mass-energy and don't respect the arrow of time because they are not real positive energy so they interconnect past and future symmetrically in precisely determining the electromagnetic force in QED.

Because mind is complementary to quantum uncertainty, it is complementary to the transactional milieu. This doesn't mean it can send classical signals from the future to the past, but it means that its volition can and does reflect these 'virtual' influences. That's why we intuitively feel and perceive we have active agency over the universe and veridically perceive this to be the case and perceive that we are acting predictively by the conscious presence of mind, while also plotting out the next move, where possible cognitively. It may seem counter-intuitive that standing in for the apparent randomness of uncertainty is all there is to volition but that's enough to completely determine and to utterly change the course of history, as we know.

Stan: Chris you said: "As you know I also have a relationship with Psi. It's just a crazy knack that I seem to possess" If you can demonstrate your ability to do Psi, you can get a Nobel prize! Can you give an example of your Psi ability?

Chris: If we can't own our own consciousness I don't think it right to say we possess Phi but we are responsive to it and share its innate capacity. I simply said it was a knack I possessed. That knack is open mindedness to uncanny correspondences in the flow of ongoing experience.

I am happy with Radin, Bancel & Delorme (2021) producing research supporting an influence of mind on entanglement and other Psi results that may have statistical significance. But these are attempts to produce verifiable results, indicating an effect under repeated instances, which make them statistically significant. This tends to be like an IID (independent identically distributed) quantum experiment that converges to the Born probability interpretation, but it depends on the exact nature of the experimental process undergone.

I really like the simple concise treatment of Gallego & Dakić (2021) showing that, in non-IID processes, the quantum description can prevail in macroscopic situations. So let me try to explain where I see what people call Psi is coming from. I am particularly interested in causality-violating conscious experiences that involve time and implicit anticipation, particularly under shifting contexts in real life where each event changes the context, so there is no IID. This is going to strike these all out of scientific proof because we can't apply statistical analysis to non IID events as they are adventitious, as we know with evolutionary mutation, but there is a reason why this is likely to be critical.

We accept that the brain has evolved to be a predictor of environmental crises of survival and opportunities for food and reproduction. We know the perceptual brain has evolved to be a predictor of emerging situations, evidenced by anomalies such as flash-lag illusions and mainstream ideas such as Graziano's attention schema theory AST. This makes excellent evolutionary sense and explains why the brain has evolved to ensure the survival of the organism, through massively parallel computing that doesn't stall in an exponential runaway, like serial computers facing the travelling salesman problem, so like Anil Seth we can describe the brain as a kind of prediction machine, using consciousness efficiently do do its work in real time, even if this is a kind of hallucination for efficiencies sake.

Now we come to the hard part. Evolution has not only selected massively parallel real time predictive machines, but subjectively conscious ones. So the same argument has to apply to subjective consciousness. So we have to address the question of why evolution has retained subjective consciousness all the way to mammals, primates and humanity, apparently universally across metazoa if subjective consciousness in itself has no predictive power over and above objective brain function.

The hard problem exists because (1) all our experience, including all knowledge of the objective physical universe is derived subjectively, (2) subjectivity is categorically inconsistent with pure objectivity and cannot be finessed into it by any Zeno's paradox easy problem approach, and (3) edge of chaos brain dynamics, combined with phase coherence processing mean the physical brain is a self-critically unstable system, uncertainly poised in the very conscious states we are considering, making proof of causal closure impossible.

So subjective consciousness must have a critical predictive advantage for it to be universally retained as central to brain function sitting right in the centre of the cyclone of edge of chaos.

When we walk down the street, we can consider that we are highly determined by our circumstances, going to the supermarket for example 50 m down our side street from here. We may be thinking some very obvious thoughts like worrying about Ukraine, but when we turn the corner just about anything can occur, including nearly getting run over.

So about half our active lives are spent dealing with defined causal aspects and the other half are accidental things that come in from left field. This is living in the quantum uncertain conscious universe. The causal circumstances are the Schrödinger equation part and the accident waiting to happen is cat paradox collapse of the wave function. Because our brains transcend IID, both processes are playing out seamlessly together. Brain computational predictivity is there to deal with the Schrödinger part and subjective consciousness to deal with causality-violating quantum collapse part of daily existence.

To be able to be predictive, subjective consciousness needs to be reflected in the sort of interactions described in the transactional interpretation and special relativistic Feynman formulation, where tellingly, even the exactly determined values of the electron magnetic moment are found with stunning accuracy by integrating over both past and future components of the wave functions. The transactional approach which deals with real particle exchanges gives an intuitive picture of this implicit predictivity, but it all comes down to how a many-to-many transaction collapses into a single real particle exchange and whatever way we look at this it is a collapse from potential past and future states to a single set of pairs of these, so it's not moving either direction in space-time but across it transversely. As I noted above, I don't have the final answer on this and suspect that no causal description is possible although I call it transcausality, because to do so would be to commit a causality violating space-time process to be causally explained, so it may forever be hidden in the entanglement which extends to the wave function of the universe as a whole (Hartle & Hawking 1983). However in this picture, we as subjectively conscious beings are INSIDE this entangled phenomenon and are thus intuitively conscious of it in our changing circumstances.

This means that our circumstances, which the Eastern Wisdom Tradition call karma (although with a more moral tone) are a product of cosmological entanglement – in the mysterious hidden variable problem. That's all well and good, but we know about Bayes' theorem, so many people discount subjective reports of coincidence, or synchronicity as being false predictions resulting from selecting only the verifying cases and ignoring the contradicting ones. The trouble with this argument is essentially that it only works with IID processes which we know converge to the Born probability. When we are dealing with sheer idiosyncrasy, we are dealing with non-IID quantum "science fiction", but subjective conscious volition is anything BUT science fiction. If anything neuroscience is fiction denying volition. But the key point here is that we can't use Bayes' theorem estimates in singular on-IID events.

So what is the answer to your Nobel prize-winning question? Well it's this. If we allow ourselves to entertain the primacy of consciousness, we enable our minds (and brains) to enter into a heightened form of intuitive awareness, where some of our attentive, perceptual and cognitive efforts go into actually looking at, and entering into, the flux of experience. Put in a very clunky way by meditators, who are far too disciplined in their one-pointed focus to appreciate the full dimensions, unless they completely abandon themselves to the abyss, this is called mindfulness. That is allowing our mind to simply resonate with nature in its vast space-time ramifications arounds us, as animals do, to make sure they can actually hear the hiss of the snake strike over the swishing of the long grasses and the chirping cicadas.

So what about my Psi? Sometimes I have really striking qualitative experiences which have the character not just of everyday coincidence, but something else at the bottom of the billabong as the Australians say. Precognitive dreams that are registered and come veridically true are examples. I hated writing a song that later proved to have tragic precognitive echoes of specific details of 9-11 that can also be explained to some degree given the subject matter, but

the qualitative details remain uncanny to this day although similar precognitive results are cited by Bem (2012) and Bem et al. (2016). These results have been analysed by Rabeyron (2020).

But why would we spend time speculating on this? In the same way, subjective consciousness is transformative over the physical universe, through efficacy of volition, we don't have time to save the world from a perilous fate dwelling on magic tricks. We need to do the good thing for life as a whole, while we are here and time is short. But Brahman accompanies me as I labour and the great virtue of entheogens is that the whack they give under the right circumstances can last a lifetime, or at least a seven year fast, because, when you fall outside the bubble of perception, you are never completely in the closed causality box any longer.

But there is more to this. The circumstances of the world may look like they are hugely deterministic laws of mass action, leaving us helpless. Empires rise and fall and their huge armies with them, in clashes of the titans as if everything is brute force, of tectonic fire and tsunamic flood, but consciousness and the human conscious world view are both transformative and critically unstable. When Nelson turned his blind eye to the telescope in the Battle of Copenhagen, an alternative history was created. Perceived realities are in flux. The Weltanshauung of Immortality is an infectious concept with a pandemic R0 very delicately poised at 1, just reproducing itself without extinction. One tiny shift and the entire flux of history can be transformed back to immortal Paradise. So the entire stakes are caught in a single cat paradox experiment that encompasses all of us.

Stan Klein: I'm pleased that we are in general agreement with standard science. One topic where there might be differences is on the topic of psychic phenomena. Do you think that telepathy might be possible, in violation of the presently known 18 wavicles?

Chris: My response is sheer speculation, off the cuff. If Bob tries to run a telepathy experiment and thinks a specific planned thought and 'sends' it to Alice and something enters Alice's head out of the blue, this is very hard to distinguish from a quantum uncertain 'cat paradox' event, and Alice's brain would have had to be in a highly uncertain dynamical state, because otherwise the causal circumstances of her brain function are forcing her brain to see Bob's thought. If that were the case it would take a strong wavicle interaction we could probably measure or falsify. But I don't think that's the case, even if Psi experimenters can get a sigma out of their experiments.

But that's not how I think this works. I think the possibility is that conscious brains use quantum entanglement and can sometimes share entangled states. This again is off the cuff, but I would see brain states as dynamical quasi-particles corresponding to phase coupled global excitations. Now the actual more common context is not an experiment, but two people who know one another, say it's me and my mum, because this happened a lot when she was alive. Because we know one another (except she's gone) there are certain dynamical brain states that can become 'engrammed' in memory, like my sense of my mother's presence and her sense of me, her son, that form a kind of familial collective consciousness.

So then I suddenly get the idea to call my mum because I haven't done so for a while and that's this quasi-exciton emerging in a non-IID way out of the 'engram' milieu, and I call her, and her phone rings and that sets off the other entangled part of her quasi-exciton that got entangled with mine last time we spoke, and of course a call from me is on the cards too, and times before that. So I say "Hi and she says "I was just thinking of you!" This is also the Aboriginal dream time speaking. They (and twins) suddenly notice something is amiss in their psyche and realise their uncle, or sibling, has passed away somewhere far off, although Bayes' theorem might claim she was always thinking of me!

Modern culture is very bad at this kind of thing because we either think flat stick in a mechanistic way or we meditate in a controlled mindful way and never really let the winds of uncertainty pass through our consciousness any more. So both spiritual practices and practical realities can block our sensibilities. The key point here is how are we going to disprove this using the standard model? It's just as bad as the hard problem. If quantum anticipation is possible and conscious volition is real, all these other possibilities are on the scientific "table top of reality", as Carlos Castaneda put it, at the far edge of brute certainty!

Consciousness and Wave Function Collapse

An important feature of our description of both the Schrödinger wave equation determining particle probabilities and the collapse process resolving them into eigenvalues, is how particle states are created and annihilated. For example a

Geiger counter is particle annihilation in a scintillation count and in a quantum interference experiment the photon is created in a hot filament, or from a voltage drop in a light-emitting diode, traverses the slits as a wave and is then annihilated as a particle by an atom on the photo-plate becoming excited. These are described effectively as discrete transitions in multi-particle states and quantum field theories.

If we start with the Schrödinger equation for the potential plus kinetic energy of the one-dimensional time-independent quantum harmonic oscillator:

$$\hat{H}(\psi(x)) = \left(-\frac{\hbar^2}{2m} \frac{d^2}{dx^2} + \frac{1}{2} m \omega^2 x^2 \right) \psi(x) = E \psi(x)$$

and change variables, by letting $x = \sqrt{\frac{\hbar}{m\omega}} q$, we have $\hat{H}(\psi(q)) = \frac{\hbar\omega}{2} \left(-\frac{d^2}{dq^2} + q^2 \right) \psi(q) = E \psi(q)$.

But we can confirm that $-\frac{d^2}{dq^2} + q^2 = \left(-\frac{d}{dq} + q \right) \left(\frac{d}{dq} + q \right) + 1$, so if we let

$$a^\dagger = \frac{1}{\sqrt{2}} \left(-\frac{d}{dq} + q \right) \text{ and } a = \frac{1}{\sqrt{2}} \left(\frac{d}{dq} + q \right)$$

We have $\hbar\omega \left(a^\dagger a + \frac{1}{2} \right) \psi(q) = E \psi(q)$. So $\hat{H} = \hbar\omega \left(a a^\dagger - \frac{1}{2} \right) = \hbar\omega \left(a^\dagger a + \frac{1}{2} \right)$.

In quantum field theories and many-body problems, one works with a_i^\dagger and a_i as creation and annihilation operators of quantum states for both bosons and fermions. In second quantisation, with occupation numbers for indistinguishable states, the occupation number for fermions can only be 0 or 1, due to the Pauli exclusion principle, while for bosons it can be any non-negative integer. This gives rise to the bosonic photon fields of quantum electrodynamics and the fermionic Dirac fields of electrons and other fermions.

These operators become:

Bosonic: $[a_i, a_j^\dagger] \equiv a_i a_j^\dagger - a_j^\dagger a_i = \delta_{ij}$, $[a_i^\dagger, a_j^\dagger] = [a_i, a_j] = 0$,

Fermionic: $\{a_i, a_j^\dagger\} \equiv a_i a_j^\dagger + a_j^\dagger a_i = \delta_{ij}$, $\{a_i^\dagger, a_j^\dagger\} = \{a_i, a_j\} = 0$.

Where $\delta_{ij} = \begin{cases} 0 & \text{if } i \neq j, \\ 1 & \text{if } i = j. \end{cases}$, $[g, h] = gh - hg$ is the commutator and $\{g, h\} = gh + hg$ is the anti-commutator.

In quantum electrodynamics, fig 71(e) the field is described as a fluctuating sequence of virtual particle states bounded by the incident and emergent real particles. Applying energy to the field can result in some of these virtual particles becoming real, as in radio emissions from transmission towers. In this description the field and its network of real and virtual particles is clear, but the wave functions are hidden in the Green's function propagators which determine the probabilities governing the virtual particle interactions. One way to do quantum mechanics is to calculate a wave function and operate on it with quantum operators. Another way is to directly consider amplitudes for a given process, such as 'the amplitude that my particle starts at point y at a time t_y and ends up at point x at time t_x '. This amplitude is known as a **propagator**. Propagators represent an alternative to wave functions that enables us to extract all of the same information and more.

The time-dependent equation that governs the change of a wave function $\phi(x, t)$ is the Schrödinger equation

$\hat{H}(\phi(x, t)) = i \frac{\partial \phi(x, t)}{\partial t}$. Each Green's function takes a wave function at some time and place (y, t_y) and evolves it to another time and place (x, t_x) . We integrate as follows to take into account the superimposed path integral effects of the Green's functions: $\phi((x, t_x)) = \int dy G^+(x, t_x, y, t_y) \phi(y, t_y)$. This means that the wave functions are still in the process, but being used to calculate the ongoing particle amplitudes at all space-time points.

Interactions, such as the absorption of a photon, by an atom on the photographic plate, are described as discrete transformations and the linear Schrödinger wave equations are just rules for calculating probabilities of particle interactions. Thus there is no actual wave function description of the entire quantum interaction in the field description, as in the transactional collapse in fig 73 where the offer wave is linear and spreading with respect to the emitter and the confirmation wave is linear with respect to the absorber but the transaction is more like a phonon.

A central question in the universe is just how much collapse takes place independent of conscious observation of it. The standard way of dealing with collapse, without requiring consciousness, is to cite decoherence through interaction with third-party quanta. Zurek (1991) initially proposed a simple exponential collapse of the off-diagonal elements as a quasi-explanation for the loss of coherence into classical eigenfunctions and has elaborated this since into quantum Darwinism by the effective survival of more robust states (Zurek 2009) .

The trouble with this is that, as described in quantum computing scenarios, and in the Feynman notation (via the Green's function propagator), third party interactions are still treated as effective wave function entanglements, which can deepen rather than solve the problem. In Feynman notation for example particle scattering is the same diagram as electron positron creation and annihilation and annihilation IS treated as wave function collapse via the discrete operator involved. This means that any interaction with third party quanta can be interpreted as either (1) collapsing the wave function or (2) as introducing multi-particle entanglements, as in GHZ and W-states.

If we take a decoherence view of the cat experiment, a single radioactive particle quantum tunnels as a wave out of the nucleus and then triggers a Geiger counter by interacting as a particle to induce charges that can be picked up and used to classically break a flask of HCN killing the cat, so that when we open the box it is dead. This is the chain that von Neumann, is contemplating in his sweeping spread of possibilities, where "collapse" could take place anywhere, from the first particle interaction, to the consciousness of the observer opening the box and seeing the cat.

The nub of the problem is that it is only in our conscious view of the cat experiment, or any other quantum measurement experiment, that we see the projection on to eigenstates occurring in our particle-dependent "classical" view of the conscious universe. We can imagine that the photons in the Sun's light come from collapsed wave functions, and we can imagine that cat paradox collapse happens the moment the radioactive particle causes a charge shower in the geiger chamber but we don't actually know. Speculation is not physical science! So before intelligent life evolved, the entire universe could have remained wildly entangled without there being any contradiction. That's what the Everett interpretation and its seamless undetectable branching confirms. The same with the Geiger counter states.

Now we can get around this by asserting that decoherence is a primary source of wave function collapse OR multi entanglement, but we really can't tell the difference until we open the box. If we take Zurek's off diagonal elements decaying and examine this in terms of multi-particle entanglement, the original two particle entanglement does become degraded by further entanglements due to extraneous added correlations confounding the simplicity of the original entangled state towards classicality, so the entangled conclusions also look like collapse to an eigenstate.

Again this doesn't mean that consciousness is the only thing that can lead to collapse, because decoherence is setting it up smoothly, if in fits and starts, all the time through multi-particle "entanglements". Hence other quanta and macroscopic systems can act as "observers" too. This tallies very neatly with macroscopic instruments precipitating the process, but it leaves open an undecidable question – just how collapsed is the physical universe independent of our perceptions of it? The only thing we are certain of, is that the cat to our conscious perception looks vivaciously alive, or dead as a door nail, as well as the bushes waving in the wind as we walk down the street and the unexpected rain shower that is breaking around us. That's right where the cookie crumbles for physics.

All "Randomness" arises ultimately from Quantum Uncertainty

Randomness has been described as having two sources, one epistemic about our state of knowledge of a system and the other ontic, about the actual physics of reality, perhaps consisting of two forms, quantum uncertainty, and the supposed randomness of molecular kinetic processes, but these are actually all sourced in quantum uncertainty.

If we think of a chamber filled with helium atoms and consider one atom in the chamber, viewed classically, this is 3-D billiards and we know multi-body billiards is chaotic because small differences in the position of any ball colliding with another causes larger deviations in their positions in the outgoing trajectories. If we view this quantum mechanically, it

is a 3-D interference experiment in which the apparatus is all the other atoms and the chamber itself. Suppose we release a single helium atom through a very small aperture at time zero. As it proceeds through the chamber, its position becomes indeterminate through wave spreading in the same way a photon does.

This is interesting and requires further thought because it is a complex system with a lot of bound particles, but the experiments on large molecules show clearly that this is taking place. This means that successive collisions result in exponentiating increases in the uncertainty of position and the indeterminacy of the trajectories, so the entire concept of the atoms as “particles” having some other kind of randomness is derived from chaotic amplification of the uncertainty of position of each of the atoms in the chamber. This effectively means that all the perceived randomness in the kinetic process was derived originally from positional quantum uncertainty, also amplified by the chaotic boundary conditions of the interacting atoms.

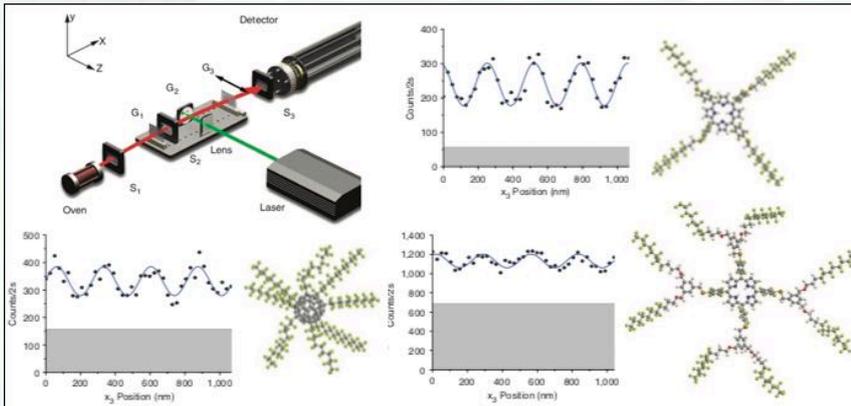

Fig 102b: Molecular interference demonstrated for three large molecules (Gerlich et al. (2011)).

As far as I can see this process extrapolates all the way into real life, where we walk around the corner and nearly get run over on the way to the supermarket, because all these uncertainties in life, although we think the universe looks “classical” are just larger more complicated instances of unmitigated amplified quantum

uncertainty, obviously including mutation, ageing, cancer and mortality itself, as well as winning the lottery! So I think we just have two sources of “randomness” the epistemic form is just partial observation through sampling subpopulations and observational uncertainty to do with the vagaries of the ontic form above and quantum uncertainty itself as the ontic form. Notice also that this means butterfly effect systems are really using quantum uncertainty to generate their ergodicity, so tornadoes are inflated quantum systems that might also be “conscious” if subjectivity also occurs at the quantum level through wave function sensitivity throughout space-time and wave function collapse.

To assume this is all random is a dangerous assumption if we don't actually know the underlying process is fundamentally random. Lots of classical processes can appear quasi- or pseudo-random and are used as random number generators. Chaotic processes and edge-of-chaos transitions frequently display ergodic behaviour due to the spreading action of the butterfly effect's positive Lyapunov exponent. Quantum measurement also has features of ergodicity that make us use the notion of randomness normalised by the wave function amplitude to explain the probability interpretation, but that's a gross simplification. Schrödinger's cat is either very much alive or stone dead when we view it. It's not an alive/dead superposition, nor is it in a random state. Entanglement gives us a hint that more is going on because the detector stats at either end show apparently random polarisations but when we do Bell theorem sampling we find they are powerfully correlated, even ‘deterministically’ complementary, when we sample at arbitrary relative orientations. Clearly uncertainty can and does handle multi-quantum entanglement which is called decoherence and it probably pervades the entire universe and its compound wave function.

Hidden variable theories assert that there is a process underlying quantum uncertainty, which is by default assumed to be “random”, but the onus on scientific proof lies as much with establishing such a source of “pure” randomness in the universe, as it does finding a succinct hidden variable theory transcending those like the pilot wave theory in a full explanation.

As previously noted, Symbiotic Existential Cosmology favours hidden variables, rather than randomness on the basis:

(1) The verification of Bell entanglement was a confirmation of the EPR claim and Einstein's quote:

God does not play dice with the universe.

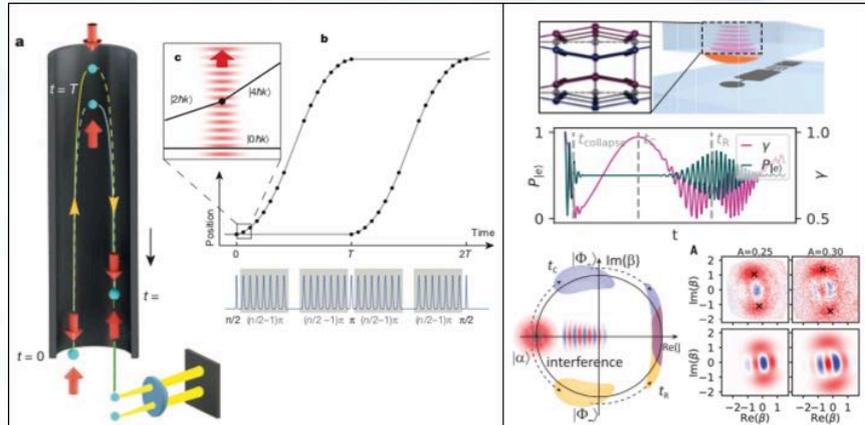

(2) The transcausal view of quantum transactions being a complex underlying hidden variable process, which is also shared by (3) superdeterminism violating statistical independence, (4) non-IID processes in biology not converging to the classical and (5) theories in which quantum measurement may contradict objective reality through process entanglements extending beyond Bell state entanglements. The transcausal aspects of transactional quantum collapse may make such a naked theory impossible to establish, meaning that both the hidden TOE and assumed randomness become undecidable propositions, which intuition can penetrate empirically, but logical proof cannot.

So then we come to karma. It's not moral, but the ultimate manifestation of quantum uncertainty in why things just happen to us. Until it is proved otherwise, I take the position as an 'avatar' that the living present is a unique karmic instance and we are treading on thin ice every step of the way. So the answer about enlightenment is not to vacate your karma, but to look very carefully long and hard into it, because the bell tolls for us.

Fig 102c: The BEC juggling and Sapphire jiggling experimental results.

We can't SEE Schrödinger Cats, but we can FEEL them!

Here is a possible denouement to the cat paradox ... this is a discovery process in the completion.

A BEC is an unlimited number of bosons (or integer spin atoms) in the same wave function, like a laser, and as we know, giving lectures by laser pointer can last as long as we push the button. But we can prepare a system in a superposition of states e.g. a quantum dot or BEC and hold it as long as we want in this entangled state until we choose measure it in some way through a particle absorption. So what IS an experiment using temporal separations falling within Heisenberg uncertainty limits? We'll see in a paragraph or two as the cat collapses and the penny drops!

Kovachy et al. (2015) throw a Bose Einstein condensate up like a juggling ball so two cusps end up in a spatially separated superimposed state:

We achieve long free-fall times by launching a Bose–Einstein condensed cloud of $\sim 10^5$ ultracold 87Rb atoms into a 10 m atomic fountain using a chirped optical lattice²⁴. After the lattice launch, we use a sequence of optical pulses to apply a beam splitter that places each atom into a superposition of two wave packets with different momenta.

The sapphire experiment (Bild et al. 2023) poses yet another situation where we have an acoustically oscillated atomic lattice that can end up superimposed between two oscillatory states with 10^{17} atoms involved.

Schrödinger's original thought experiment was not just so that two macroscopic states were superimposed but diabolically, so that the two states were biologically impossible, since live cat / dead cat is "unlawful" for the cat to exist in this superimposed state. Contrast that with the sapphire, where the two states are two very slightly different arrangements of a molecular lattice where there is no more inconsistency than in an ordinary interference experiment.

Now in a cat paradox experiment, we simply have a Geiger counter and a weak source emitting an average of 1 particle per sec and we leave the cat in the box for 0.5 secs and open it. But the cat is also a conscious organism, so what has actually happened is that the Cat starts to smell cyanide and at that point its fate is sealed, so the cat made the first conscious observation by detecting HCN molecules by smell and it has nothing to do with the experimenter opening the box.

John Kinemann suggested that a form of autopoiesis might prevent an organism becoming superimposed:

But it says, "That means a true Schrödinger's cat is still far from being realised." Meaning it has not been demonstrated for a living organism. Nor do I think it will be because life preserves quantum superposition for decision making, but also closes the causal loop to preserve life and identity. That decision has already been made by the organism. If every aspect of the organism were a real time

choice life could not be sustained. So an actual cat is much more complex than any of these lab experiments that demonstrate only one necessary principle.

I replied that consciousness has to collapse the wave function because it's the only way to affect the universe without causal conflict with brain function. It doesn't need further causal loops except as an indirect effect of this constraint.

Now, on reflection, I can effectively take John's argument and turn it inside out. We are witnessing superpositions of states all the time when our brains reach an unstable butterfly-effect-sensitive dynamical state through just the uncertainty window CN is pointing to. This is what we call making an uncertain intuitive decision, where the unconsciously competing factors interfere. Pair-splitting EPR experiments are a distraction, because they are designed to demonstrate entanglement Bell violations, but superposition is manifest in all uncertain situations. So when we have an "Aha!" moment, or when we simply make an arbitrary, idiosyncratic or creative choice, we are collapsing a superposition we have actually perceived internally through our very sense of mounting "uncertainty".

It is this transition that we are experiencing all the time, each of which IS a Schrödinger cat before during and after collapse. We can't see these Schrödinger cats because they are hiding in "plain sight" in our sense of decision making, just as I came to this conclusion, formulating to myself what the hell is going on with these goddamn cats and why we can't see them!!! So the answer is that we can't SEE a Schrödinger cat but we FEEL them all the time and that's what intuition IS! So the real world is not as classical as it appears, but as quantum uncertain as our inner feelings indicate.

Theories of Everything and their Impact on Consciousness

In the 20th century, two theoretical frameworks emerged for formulating the laws of physics. The first is Albert Einstein's general theory of relativity, that explains the force of gravity and the structure of spacetime at the macro-level. The other is quantum mechanics, which uses wave-particle complementarity a Hamiltonian wave equation and probability principles to describe physical phenomena at the micro-level.

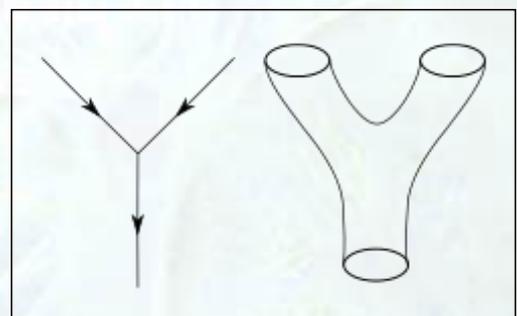

Quantum field theory is the application of quantum mechanics particles and forces such as the electromagnetic field, which are extended in space and time, modelled as excitations in the fundamental fields. One computes the probabilities of various physical events through perturbative quantum field theory using Feynman diagrams (fig 71(e)) depicting the paths of point-like particles and their interactions.

Einstein's general theory of relativity treats time as a dimension on par with the three spatial dimensions; in general relativity, space and time are not modelled as separate entities but are instead unified to four-dimensional spacetime. In this framework, the phenomenon of gravity is viewed as a consequence of the geometry of spacetime.

Canonical quantum gravity is the attempt to quantise the canonical formulation of general relativity (or canonical gravity) as a Hamiltonian formulation of Einstein's general theory of relativity. All canonical theories of general relativity have to deal with the problem of time. In quantum gravity, the problem of time is a conceptual conflict between general relativity and quantum mechanics. In canonical general relativity, time is just another coordinate as a result of general covariance. In quantum field theories, especially in the Hamiltonian formulation, the formulation is split between three dimensions of space, and one dimension of time.

Fig 103: Feynman diagram vertices become 2D string surfaces.

Roughly speaking, the problem of time is that there is none in general relativity. This is because in general relativity the Hamiltonian is a constraint that must vanish. However, in any canonical theory, the Hamiltonian generates time translations. Therefore, we arrive at the conclusion that "nothing moves" ("there is no time") in general relativity. Since "there is no time", the usual interpretation of quantum mechanics measurements at given moments of time breaks down. This problem of time is the broad basis for all interpretational problems of the formalism.

String theory is the idea that the point-like particles of quantum field theory can also be modelled as one-dimensional strings. The interaction of strings is defined by generalising the perturbation theory used in ordinary quantum field theory. At the level of Feynman diagrams, this means replacing the one-dimensional diagram representing the path of a point particle by a 2D-surface. Unlike in quantum field theory, string theory does not have a full non-perturbative definition, so many of the theoretical questions remain out of reach.

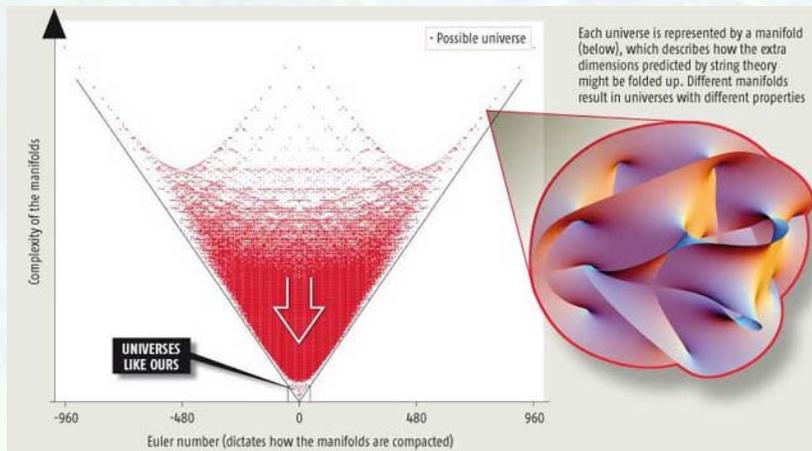

Fig 104: Two papers (arXiv:1806.08362, 1806.09718) suggest the overwhelming majority of multiverses in this landscape are assigned to the swampland of unviable universes, where dark energy is unstable, also reviving the popularity of time-varying dark energy models such as quintessence. The Calabi-Yau manifold illustrated is just one compactification, which shows a local 2D cross-section of the real 6D manifold known in string theory as the Calabi-Yau quintic.

The original version of string theory was bosonic string theory, but this version described only bosons, a class of particles that transmit forces between

the matter particles, or fermions. Bosonic string theory was eventually superseded by superstring theories which describe both bosons and fermions, using supersymmetry in which each boson has a counterpart fermion, and vice versa, but a symmetry-broken asymmetric complementarity may be required. A heterotic string is a closed string (or loop) which is a hybrid ('heterotic') of a superstring and a bosonic string. String theories require extra dimensions of spacetime for their mathematical consistency. In bosonic string theory, spacetime is 26-dimensional, while in superstring theory it is 10-dimensional, and in M-theory it's 11-dimensional. In compactification, some of the extra dimensions are assumed to "close up" on themselves to form circles. In the limit where these curled up dimensions become very small, one obtains a theory in which spacetime has effectively a lower number of dimensions and the compactified dimensions represent internal states such as colour, flavour and charge exemplified in the 10 dimensions of $U(1) \times SU(2) \times SU(3) \times (3+1)D$ space-time.

A brane generalises the notion of a point particle to higher dimensions. For instance, a point particle is a brane of dimension zero, while a string is a brane of dimension one. In string theory, D-branes are an important class of branes that arise when one considers open strings. As an open string propagates through spacetime, its endpoints are required to lie on a D-brane. The study of D-branes in string theory has led to important results such as the AdS/CFT correspondence (fig 106), which has shed light on many problems in quantum field theory.

One popular way of deriving realistic physics from string theory is to start with the heterotic theory in ten dimensions and assume that the six extra dimensions of spacetime are shaped like a six-dimensional Calabi–Yau manifold. Such compactifications offer many ways of extracting realistic physics from string theory. Each of these different shapes corresponds to a different possible universe, or "vacuum state", with a different collection of particles and forces. String theory thus has an enormous number of vacuum states, typically estimated to be around 10^{500} , sufficiently diverse to accommodate almost any phenomenon that might be observed at low energies.

Laura Mersini-Houghton (Holman, Mersini-Houghton & Takahashi 2008, Hooper 2022) notes how she discovered her multiverse theory that resolves this problem:

I began thinking about all this in the early 2000s, around the time that string theory was the leading candidate for a "theory of everything" that unifies gravity with the other three quantum forces to explain our universe. String theory is the idea that nature at a fundamental level is 11 dimensional and particles are actually just the bit we can see of tiny loops of vibrating strings. With string theory, after curling up the extra spatial dimensions to make them sufficiently small to be invisible, you end up with a whole landscape of possible initial energy states, or potential big bang energies, that could start a whole family of different universes. At the time, string theorists thought this was really bad because they were looking to end up with only one universe – one that looked like ours – described by one theory, and they were ending up with a nearly infinite number of universes. But to me it was great news because I needed a fundamental theory to provide that pool of energies that would allow me to ask the question, "why did I start with this one rather than something else?"

I had realised something that seems obvious in hindsight. We know for sure that our universe was very small in its first moments of existence. Therefore, it obeys the laws of quantum physics. What dawned on me specifically was that, based on the wave-particle duality of quantum mechanics, I could think of the universe as a wave function instead of as an object. The wave function is the mathematical entity that encodes quantum probabilities. But you can imagine it as a tree made up of many branches, each of which can produce a universe, and it spreads through the energy valleys of the string theory landscape, from where it takes its big bang energy.

You get these branches, these many worlds, but you need to decouple them from each other – you need to break that quantum entanglement. In my hypothesis, the string theory landscape broke the entanglement and separated out the many worlds. Somehow, early on, our universe went through a quantum-to-classical transition. It became a classical object where each event is determined with certainty. This could not have been the case unless the branches of the wave function of the universe completely decoupled. All the branches decouple as they are going through cosmic inflation. This is the phase, shortly after the big bang, when the universe went through a period of exponential expansion in size. My proposal was that, if this decoupling did happen, we would be able to see the remnants of it in the cosmic microwave background [or CMB], the radiation left over from those first moments of our infant universe. The idea was that, as the branches decoupled, traces of the entanglement would have been left behind.

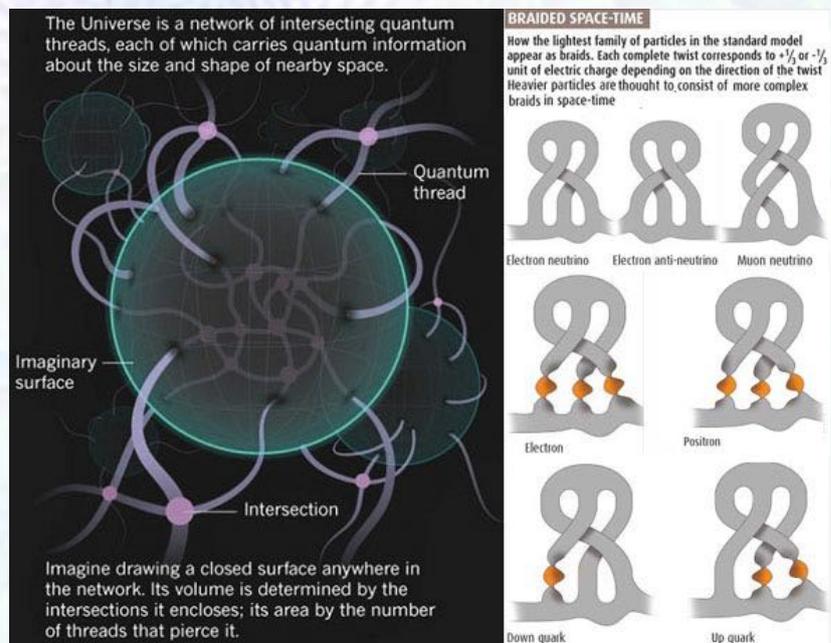

I made a series of predictions with Richard Holman and Tomo Takahashi in 2005 and 2006. We said we would be able to see signatures of this early entanglement. Our present universe is just a rescaled version of its infant self, with all its "birthmarks" still there. If you think of all these quantum universes as tiny quantum particles, they were all interacting with each other – gravitationally they were pulling on each other, and that left scars in our sky. One prediction was the existence of a giant void or cold spot in the CMB. And such a void [about 900 million light years wide] was found in the observations of the Wilkinson Microwave Anisotropy Probe, a space-based observatory. It was confirmed by the Planck satellite, which also observed the CMB. We were the first to show how you can actually test the multiverse and that you don't need to go beyond the universe's observable horizon – you can just see it in our sky.

Loop quantum gravity (LQG) aims to merge quantum mechanics and general relativity, incorporating the Standard Model into the framework established for the pure quantum gravity case. It is an attempt to develop a quantum theory of gravity based directly on Einstein's geometric formulation rather than the treatment of gravity as a force.

The quantum states in the theory do not live inside the space-time. Rather they themselves define spacetime. As a theory LQG postulates that the structure of space and time is composed of finite loops woven into an extremely fine fabric called spin networks. The evolution of a spin network, or spin foam, has a scale above the order of a Planck length, approximately 10^{-35} meters, and smaller scales are meaningless. Consequently, not just matter, but space-time itself, adopts an atomic structure. A spin network represents a "quantum state" of the gravitational field on a 3-dimensional hyper-surface. A spin foam is a topological structure made out of two-dimensional faces that represent one of the configurations that must be summed to obtain a Feynman description of quantum gravity.

Fig 105: Loop quantum gravity is an alternative to superstring theory. Right: Braided space-time gives an underlying basis for unifying the fundamental particles.

When the spin network is tied in a braid, it forms representation of a particle, which can have electric charge and handedness. Some of the different braids match known particles, where a complete twist corresponds to $+1/3$ or $-1/3$ unit of electric charge depending on the direction of the twist.

Heavier particles are conceived as more complex braids in space-time. The configuration can be stabilised from space-time quantum fluctuations by considering each quantum of space as a bit of quantum information resulting in a kind of quantum computation. There are fundamental issues reconciling LQG with special relativity.

Each of these theories lead to serious questions and contradictions about the nature of time itself. String theory finesses space and time into a higher dimensional manifold which is then compactified, Canonical quantum gravity demonstrates that there is no time in general relativity, just stillness. Loop quantum gravity fragments space-time into a spin foam. Even special relativity by the Lorenz transformations, gives both advanced and retarded solutions leading to the hand-shaking between past and future of the transactional interpretation (fig 72).

We thus have to come to terms with the way our conscious experience interacts with the physical universe and whether agency can still have meaning in a timeless cosmos. To break time down philosophically into more fundamental constituents as a single series we can think of three stages of abstraction. An A-series ordering orders times in terms of whether they are objectively past, present or future. It is a dynamic ordering constantly updating with the passage of time. A B-series ordering orders times or events in terms of the relations of earlier-than, later-than, and simultaneous-with, so is unchanging. C-series events by contrast, are temporally ordered, but there is no temporal direction within the series i.e. as a betweenness ordering. In a C-series ordering, by contrast, we say only that b is between a and c.

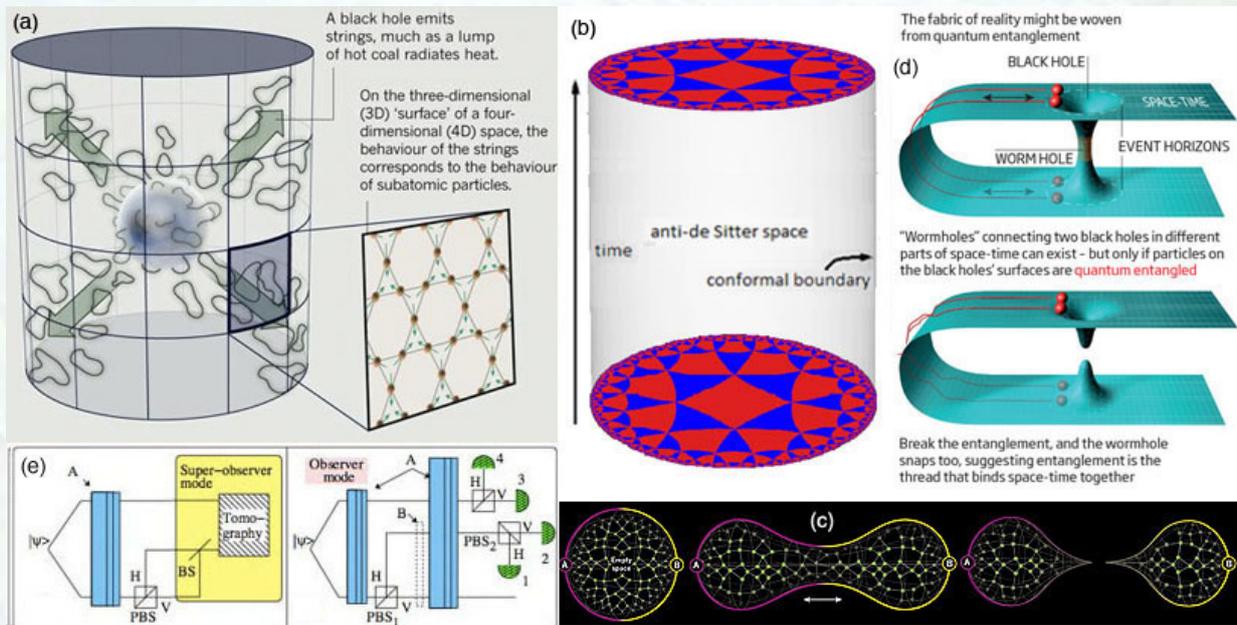

Fig 106: (a) An illustration of the holographic principle in which physics on the 3D interior of a region, involving gravitational forces represented as strings, is determined by a 2D holographic representation on the boundary in terms of QFT physics of particle interactions. (b) Einstein's field equations can be represented on anti-de Sitter space, a space similar to hyperbolic geometry, where there is an infinite distance from any point to the boundary. Maldacena (1998) discovered a 1-1 correspondence between the gravitational tensor geometry in this space with a conformal quantum field theory like standard particle field theories on the boundary. (c) Entanglement plays a pivotal role because when the entanglement between two regions on the boundary is reduced to zero, the bulk space pinches off and separates into two regions. (d) In an application to cosmology, entanglement on the horizon of black holes may occur if and only if a wormhole in space-time connects their interiors. Einstein and Rosen addressed both wormholes and the pair-splitting EPR experiment. Juan Maldacena sent colleague Leonard Susskind the cryptic message ER=EPR outlining the root idea that entanglement and worm-holes were different views of the same phenomenon (Maldacena and Susskind 2013). (e) Time may itself be an emergent property of quantum entanglement (Moreva et al. 2013). An external observer (1) sees a fixed correlated state, while an internal observer using one particle of a correlated pair as a clock (2) sees the quantum state evolving through two time measurements using polarization-rotating quartz plates and two beam splitters PBS1 and PBS2.

Many complex interactions, particularly integral transforms, involving a convolution integral of multiple components are likely to induce pseudo-random statistics. Indeed two entangled particles are able to display correlations violating Bell's inequality while the statistics of each appears random to an observer only measuring one. An example of a many-to-many correspondence suggested by Uziel Awret (2022), as shown in fig 106, is the holographic principle in M-theory or AdS/CFT Correspondence (Maldacena 1998) which gives rise to a duality between a quantum field theory on the "boundary" surface enclosing a region of spacetime, and spacetime geometry in the interior "bulk" anti-deSitter space, corresponding to a general relativity their with a negative cosmological constant. When the CFT has intractably strong interactions the dual AdS has weaker more tractable solutions and vice versa.

This is an abstraction of the duality we see in optical holograms, between the interference fringes on the 2-D hologram and the reconstitutable 3-D image it was derived from, by additive coherent light ray tracing, encoded by the wave phase, forming a tantalising bijective integral transform. Attention has been drawn to this duality as an oracle to discuss the assumed “binding problem” of how brain processes generate the coherence of subjective experience (Elliot 2019), the panpsychism structural mismatch problem (Chalmers 2016) – why macrophysical structure, e.g. in the brain seems entirely different from the macrophenomenal structure we experience, and Chalmers’ meta problem of consciousness. However, like any strict 2-component dual aspect theory, Awret’s is implicitly epiphenomenalistic and passes off the mismatch from the quantum field theory of the standard model to a dual higher dimensional abstract gravitational theory, no more like the phenomenal subjective experience than the quantum physics we know. In effect it is coopting a purely physical theory invoking an abstract duality to solve intractable string theory problems without explaining why such a dual displays any manifest subjective existence.

In the author’s view the underlying complementarity supporting conscious subjectivity in the physical universe is not such a bijective duality, as it provides complementary interactive roles for subjective consciousness to seamlessly resolve uncertainties in the unstable dynamics of edge-of-chaos processes in brain dynamics. These complementary inputs to the ongoing physical state through volition interleaving with brain states in the neural correlate of consciousness are not possible in a bijective duality.

Other research also brings this correspondence into focus. When an ice cube melts and attains equilibrium with the liquid, physicists usually say the evolution of the system has ended. But it hasn’t — there is life after heat death. Weird and wonderful things continue to happen at the quantum level. A quantum circuit acts on its basic units of information, qubits, using a standardised repertoire of gates. Some gates perform familiar operations such as addition, while others are quintessentially quantum. A “controlled NOT” gate, for example, can bind together two or more qubits into an indivisible whole, known as an entangled state. Any system composed of discrete units can be recast as a circuit, even a system that looks nothing like a computer. Leonard Susskind and co-workers (Brown & Susskind 2018, Bouland et al. 2019) applied this concept to the hot plasmas that, through the AdS/CFT duality, are equivalent to black holes. He suggested that, even after the plasma reaches a condition of thermal equilibrium, its quantum state does not stop evolving (Musser 2023). It becomes ever more complex.

Dark matter, evidenced only in the clumping and fast rotation rates of galaxies, and Dark energy, associated with the increasing rate of expansion of the universe, are likewise poorly understood. There are four basic Dark matter candidates, axions, machos (non-luminous, small stars, black holes etc), wimps (weakly interacting massive particles which might emerge from extensions of the standard model), and complex dark matter experiencing strong self-interactions, while interacting with normal matter only through gravity. Axions have become particularly interesting as candidates as other types become eliminated by limits on detection (Chadha-Day, Ellis & Marsh 2022, Semertzidis & Youn 2022, Blinov et al. 2022). Interaction with gravitational forces is deemed to be essential to explain the some 10^{120} -fold discrepancy between the cosmological constant and the standard model vacuum energy contribution.

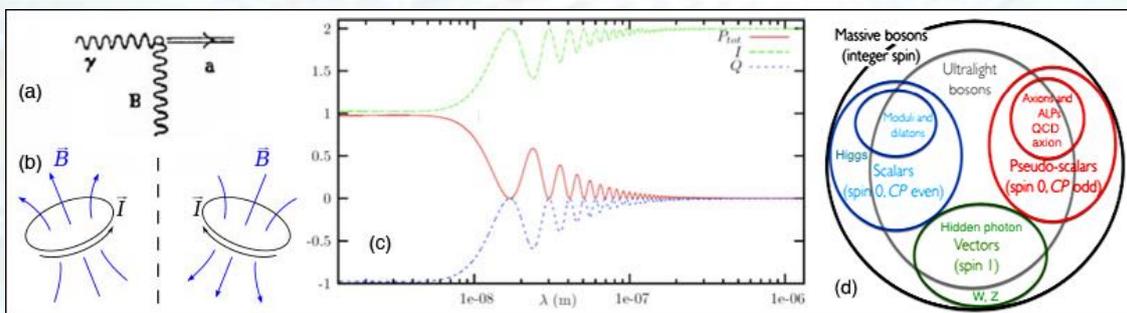

Fig 106b: (a) A photon may undergo mixing to a pseudoscalar particle - an axion - in an external magnetic field. (b) The magnetic field is a pseudovector field because, when one axis is reflected, as shown, reversing parity, the magnetic field is not reflected, but reversed, because the currents are reversed. The position of the wire and its current are vectors, but the magnetic field B is a pseudovector, as is any vector cross product $p=a \times b$. Any scalar product between a pseudovector and an ordinary vector is a pseudoscalar. A pseudoscalar particle corresponds to a scalar field which is likewise inverted under a change of parity. (d) Many extensions of the Standard Model predict additional massive bosons, beyond the W , Z , and Higgs bosons of the Standard Model. These arise naturally from the CP (charge-parity) violations seen for example in the weak force. They might be scalar (even under both P and CP transformations), pseudo-scalar (odd under both P and CP), or vector particles. The prototype for a pseudo-scalar boson is the axion, which is “ultralight” with mass $m \ll 1$ eV.

Ovchinnikov (2012) has also shown that dynamical systems in path integral formulation can be represented as topological field theories. As a result, all (equilibrium) dynamical models are divided into three major categories: Markovian models with unbroken Q-symmetry, chaotic models with Q-symmetry spontaneously broken on the mean-field level by, e.g., fractal invariant sets (e.g., strange attractors), and intermittent or self-organized critical (SOC) models with Q-symmetry dynamically broken by the condensation of instanton – anti-instanton configurations (earthquakes, avalanches etc.). Hal Cox has speculated this could help explain field theories of brain dynamics.

In philosophy, to say that a statement is truth-apt is to say that it could be uttered in some context and would then express a true or false proposition. Truth-apt sentences are capable of being true or false, unlike questions or commands. Whether paradoxical sentences, prescriptions (especially moral claims), or attitudes are truth-apt is debated. Temporal error theory is a view that is analogous to moral error theories, which deny the objective reality of moral facts, and, on the basis of this, deny that any moral claims are true. Temporal error theory, then, is the view that temporal thought and discourse is truth apt, and is false (or at least, is not true).

Can Cosmic Consciousness, or God Consciousness, Generate the Entire Physical Universe?

By contrast with abstract TOEs, or theories of everything, from superstrings to quantum loop gravity, the Vedantic tradition asserts that consciousness itself, in a transcendent cosmic form, is at the very source, generating the physical universe. Similarly, theism asserts that God created the universe. Is this a realisable perspective, or does it introduce even more inconsistency and counterfactuality into the cosmic conundrum, inconsistent with Occam's razor?

An example is Aurobindo's viewpoint, where he accepts the scientific view of biological evolution but claims a complementary process of conscious involution creating the physical substance of the universe:

According to Sri Aurobindo, in conformity with the oldest Indian scriptures, matter was created by the ultimate or supreme consciousness seeking manifestation. In order to manifest, supreme or absolute consciousness, starting from the full fluidity of the spirit, created graded planes of being, till it reached the state of manifesting the solid density of matter. Sri Aurobindo calls this the process of Involution. The involution of consciousness is the process in which the Supreme or Absolute conceals itself more and more by creating planes of consciousness of increased density, in order to create the density needed for physical manifestation. In each of the planes that were created during the involution, (called typical planes or graded worlds) the absolute or divine consciousness veiled itself increasingly till it was able to produce and manifest the various forms of solid matter.

Fig 106c: Both God and Brahman, the Vedantic cosmic mind as ultimate reality, carry aspects of the human persona and psyche in their tacit assumptions, meaning they are projections of human organismic experience onto the cosmos, not absolute cosmic realities.

We have arrived at this question by facing up to the hard problem of consciousness, that no objective arrangement of material waves or particles, no matter how complex, or integrated can, of themselves generate subjective experience, which accounts for 100% of our knowledge of reality, nor explain how we have efficacy of conscious volition over the universe in our survival-oriented and creative behaviour. But can we reverse the explanatory gap and explain the universe, as some woven or over-laid form of a consciousness, which has no underlying physical process at all? Just as particulate interaction, no matter how complex cannot give rise to the holistic nature of subjective experience, how can consciousness that we conceive of as the "observer" of holistic experience, contort this holistic realm into the particulate universe we perceive and know from detailed experiments is governed by physical laws of nature, as specific and critical to life as the standard model, without introducing even more intractable paradoxes? Neither is posing a neural monistic entity, with neither subjective nor objective manifestation, any form of solution to these profound differences which have to be interactive for subjectively aware organisms to have efficacy of physical volition.

For all the seemingly impenetrable difficulties of the explanatory gap, we at least have a good idea of how conscious life emerges in the physical universe, long after the cosmic origin, in a process that requires generation of the chemical elements of life in supernovae and then biogenesis and the evolution of life, reentry of the archaea and bacteria in the

eucaryote endosymbiosis, generating full subjective consciousness and then the rise of multicellular animals with biological brains. The very notion of consciousness arises from the alert waking state of a human or animal organism, in notions from “conscious of” our surroundings, consciousness, as opposed to sleep and coma, and self-consciousness as self-aware organismic agency. Many aspects of our subjective experience, including colour vision and spectral sound are derived from brain processing via biological receptor organs for physical modes, rather than the universe itself and hence are evolutionarily adapted and organismic. Even our ideas of self and other are processed in regions like the precuneus and temporo-parietal junction, so that in meditation and psychedelic states, we can experience union with ultimate reality and hold an ongoing notion of God consciousness. But we have no direct experience of the consciousness in others except by their vivacious behaviour and no validly meaningful knowledge of consciousness, as an absolute actuality generating the physical universe, except perhaps through our first person visionary experience.

The peak experience on psychedelic mushrooms that was the source of this cosmology, was astounding in the way it conveyed disembodied cosmic consciousness in the persona that the Vedantic tradition likens to Brahman, in the merging of individual atman or conscious self with universal cosmic consciousness, in a near-death type experience. But at the same time, it was warning me that Brahman was as vulnerable as I and the biosphere, because without the survival of life, this state of cosmic reunion, outside our biological incarnations, was as vulnerable as life itself, without surviving climax living beings to experience this transcendent reality.

This brings us to a new and different world view, or weltanschauung, via a consciousness filter theory, in which moksha is a living biological state, asymptotic to a form of cosmic consciousness, when the doors of perception are opened wide, so that the constraining filters of perception cease to be confined to the physical awareness of the world and descend deeper into the abyss of what unconditioned climax consciousness can be and become in the unfolding of life. But it doesn't assert primal transcendence of this state of reunion over the physical universe, from which it has arisen as a climax phenomenon. Both the notions of theistic deity in God, founded in intentional conscious agency and of Vedantic doctrine in Brahman, as the ultimate cosmic reality founded in consciousness itself, are thus projections of human organismic agency and conscious existence onto the entire universe and its very origin.

While God is seen as transcendent, in being both omniscient and omnipotent, the very notion carries incontrovertible archetypes of anthropomorphic agency. God has all the attributes of human emotions, from compassion, to jealousy, and genocidal anger and violence, as well as all the notions of intentionality we associate with human manufacture, in which living beings are created de novo by God's shaping in clay, or breathing the breath of life we possess into life as a whole, “*And the LORD God formed man of the dust of the ground, and breathed into his nostrils the breath of life; and man became a living soul*” or in rational thought as the doctrinal logos “*In the beginning was the Word, and the Word was with God, and the Word was God*”, all imbued with the reinforcement of moral cosmologies characteristic of urban societies in the pursuit of ultimate order, construed as in obedience to God's divine will. This leads in turn to false notions of creationism, and intelligent design, where life is construed to be merely a clockwork theistic technology of “creatures” created de novo by God, in which *Homo sapiens* rules over life as a whole:

And God said, Let us make man in our image, after our likeness: and let them have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth, and over every creeping thing that creepeth upon the earth.

But we have also discovered that the conscious complexity and sentience of life arises, not from a rule of ultimate order, but through critical phase transitions at the edge of chaos, giving rise to the evolution of increasing complexity and diversity and the very dynamical brain states characterising organismic consciousness.

When we turn to the Vedantic tradition, we can see the same process occurring, in which the rishis, in a state of deep samadhi conceived that the entire universe was made out of aggregations of divine consciousness, to make the material universe as the demi-God Brahma emerging from the dream of Vishnu out of his navel, overlooked by faithful Lakshmi. This was then made more abstract in Upanishadic notions of Brahman as ultimate reality in the abstract, standing outside life, as a cosmological absolute form of consciousness, generating the entire universe. This consciousness is also set apart from experience, as the illusory world of subjective form, or maya, particularly when confined to our organismic perception of the physical world and our egotistical survival in the mortal coil of the round of birth and death. Is it reasonable to separate pure “transcendent” consciousness from all immanent experience, when consciousness is the very ability to have subjective experience and even the most basic physical experiences, let alone dreams, memories and reflections, are essential to the continuity of life as a whole, and are thus NOT illusion?

This is where Symbiotic Existential Cosmology remains counterposed to the original Vedantic tradition, as a remedy just as it is a remedy to theism by returning cosmic agency back to us all as subjects, because it sees cosmic consciousness just as it manifests biologically, as a nascent emergent property of the eucaryote endosymbiosis becoming organismic and human consciousness realised for example in deep meditation, and the mystical visionary state, that is a climax manifestation of the living universe, whose very existence and ability to manifest is dependent on the existence of life as a whole.

Symbiotic Existential Cosmology thus postulates only primal subjectivity, as a complementary aspect to quantum reality at the cosmic origin, in a process that remains entirely consistent with physical cosmology and the likely inflationary scenario, in which both the universe and subjectivity emerge as a quantum fluctuation, rather than the Vedantic view of a transcendent super cosmic consciousness that generates the entire universe, that like all theistic cosmologies run down into chaos because of defection against the presumed ultimate order of moral good.

Primal subjectivity is conceived of as optimally compliant with the environmental boundary conditions of the filters the biological brain imposes, while giving subjective consciousness a privileged active agency, during quantum uncertain phases in neurodynamic phase transitions, central to the survival of the organism and in turn our ability to experience ultimate reality as conscious agents. This transforms from a physicalist view that conscious experience is just a shadow manifestation, a mere internal model of reality generated by physical brain processes, into a filter theory of conscious experience, as being essential to organismic life, as a holistic manifestation of subjective efficacy of volition over the physical universe, to aid and ensure survival of the sentient being, not as maya or illusion, but the biological focus that consciousness must be compliant with, for the organism to survive and reproduce and for life to flower as a whole.

We see in later Indian thought a complementarity between Shiva as the timeless cosmic conscious witness of Shakti as the dynamic force of physicality begetting both life and death in creation and destruction, then leading to universal maya or illusion, as the primal pair retreat from intimate coitus, leading to all of us sentient beings lost in the egotism of organismic consciousness, ending ultimately in the conflagration of the Kali Yuga, due to moral and spiritual decline.

By contrast, Symbiotic Existential Cosmology doesn't seek transcendence over nature, in spiritual supremacy, but immanent symbiotic integration with life as a whole, at the edge of chaos, in the natural consummation of the conscious universe, in self-becoming that IS transcendence, realised in the unfolding of life.

The Reality of Time and the Notion of Agency

In "Out of Time", Baron et al. (2022) explore both the potentially non-existent status of time in current physical cosmology and the folk notions of time that human cultures consciously and socially invoke:

The idea that time does not exist is, for many, unthinkable: time must exist. Our goal is to make the absence of time thinkable. Time might not exist. This chapter lays the groundwork for our investigation. We begin by clarifying the central target of our investigation, the folk concept of time and then motivating the idea that it is this folk concept whose investigation matters. ... Our primary focus in this book is on the folk concept, or concepts, of time. ... For now, we can think of the folk concept of time as something like the naïve view of time – the unreflective notion of time that individuals use in their everyday lives. ... When we talk of the folk concept of time we don't simply mean the way the folk think about, or conceive of time. We don't simply mean what the folk think time is like. We mean something like what the folk think (almost certainly implicitly) it would take for there to be time in a world. ... Why should we care about the folk concept of time? The short answer is that we should care about time in the folk sense, because it appears to be implicated in normative concepts and practices in which we are deeply invested; concepts and practices like moral and practical responsibility.

They note a number of versions of TOEs attempting to unify gravity and the standard model of physics:

A number of approaches to quantum gravity (QG) have been proposed. The best-known approach to QG is string theory, according to which the fundamental components of reality are tiny one-dimensional strings that vibrate in up to eleven dimensions. The chief alternative to string theory is Loop Quantum Gravity (LQG), according to which reality is fundamentally a lattice-like structure, constituted by discrete 'chunks' that are 'woven' together. Another approach to QG is the Canonical Quantum Gravity program (CQG), which applies standard quantisation techniques from quantum field theory to the gravitational field, in order to produce a quantum account of gravity (roughly in the mould of the standard model of particle physics). Other approaches include causal set theory, the asymptotic safety approach, the causal triangulation approach and the emergent gravity program.

They then consider how our philosophical notion of agency can survive the sacrifice of time itself by using causality in a local sense to create the framework for reasoning agency:

In what follows we cannot hope to spell out a full-blown realist account of agency without time. That would be a massive undertaking. Instead, we will focus on showing how the realist can respond to the two arguments we mounted earlier: the conceptual and cognitive arguments.

Let us start with the conceptual argument. ... The concept of agency at issue is one that focuses on deliberation. As already discussed, we believe it is plausible that for one to be an agent, one must be able to impose a deliberative structure. We are also inclined to accept that in order to do that, one must believe that there is some supportive structure. We nonetheless think the conceptual argument fails. It's not the case that there must be a C-series for there to be a supportive structure. Thus, one can reasonably believe that there is a supportive structure even if one accepts temporal error theory. There is thus no bar to the imposition of the kind of deliberative structure needed for agency.

Consider the idea that we need to take some things to be fixed, and unchangeable, and to be the things on the basis of which we deliberate. Consider also the idea that we take other things to be open, and malleable, and to be things about which we deliberate. Causal structure seems well suited to support both aspects of deliberative structure. There being a causal structure allows us to take as fixed, and unchangeable, those things that are causally prior to our location, and as open and malleable, only those things that are causally downstream from us. We cannot causally intervene on events that are causally prior to us, so they are excellent candidates to be held fixed and unchangeable. This brings us to the cognitive argument. Recall the basic argument: some if not all of our agentive thoughts involve temporal thoughts. Those thoughts are therefore true only if the relevant temporal thoughts are true as well. If temporal error theory is true, then our temporal thoughts are false and so at least some agentive thoughts are false too. Our response to this argument is just to concede the conclusion: yes, some of our agentive thoughts are false. Be that as it may, the falsity of the relevant agentive thoughts does not undermine agency. The reason for this is that there are other nearby agentive thoughts that are true; thoughts that invoke only causal notions.

By contrast, and at least in principle, we can causally intervene in events that are causally downstream from us, so these are also excellent candidates to be held open and malleable. Indeed, with respect to those things that are causally downstream from us we can distinguish between those that we take ourselves to be able to causally affect, and those we take ourselves not to be able to causally affect. Only those in the former category are those about which we can deliberate. Those events that are causally prior to us, in the causal ordering, or those that are causally downstream from us, but which we take ourselves to be unable to causally affect, are those things about which we cannot deliberate. So, the presence of causal structure provides a supportive structure for at least these aspects of deliberative structure.

However, we have come to see that conscious experience has depths and heights that take it far beyond the confines of rational thought and mental cognition, including emotional states, transcendent mystical states and real world states of acute anticipation as a key feature of consciously surviving immediate existential threats. Baron et al. (2022) thus also make an attempt to discuss temporal non-cognitivism in this context:

Temporal non-cognitivism is the view according to which our temporal thought and talk does not involve truth-apt beliefs, but rather, involves some other kind of attitude. So, even if our folk concepts of time are not satisfied, it does not follow that such talk is false because a fortiori it is neither true nor false. ... We find temporal non-cognitivism tantalising. We confess, though, that we are not sure how to spell out the view in a plausible manner. Given this, what we say about temporal non-cognitivism will be brief. Our aim is not to argue that there is no way to develop a version of temporal non-cognitivism. Rather, we will gesture towards what we take to be some powerful problems that the non-cognitivist must face if she is to develop such a view.

The central problem we see for temporal non-cognitivism is that it is difficult to see what our temporal thoughts might be, if not beliefs, and hence which mental states temporal talk might express, if they are not reporting beliefs. Indeed, we can only really see one way to develop this idea, and that is to take temporal thought and talk to express non-cognitive attitudes of some kind. Call such a view: temporal expressivism. The question then becomes which non-cognitive states the expressivist might identify with our temporal thoughts.

There are roughly two kinds of attitudes that one might appeal to: emotive attitudes such as regret, anticipation, nostalgia, fear, anxiety; or evaluative attitudes such as desire or preference. These are natural options to pursue, because they all display a 'temporal' asymmetry and so bear some connection to time already. ... Any plausible temporal non-cognitivism will need to provide felicity conditions for temporal thoughts such as 'it rained yesterday' and 'it rained 5 minutes ago'. After all, even the non-cognitivist about temporal thought presumably doesn't want to say that any temporal thought is as apt as any other. ... Even if felicity conditions for some temporal attitudes can be provided along these lines, there is a deeper problem for temporal expressivism. The problem is a paucity of attitudes. Whichever attitudes one chooses—emotive or evaluative—there do not appear to be sufficiently many, or sufficiently fine-grained, non-cognitive attitudes to capture all of the different temporal thoughts we have.

In principle, one can have temporal thoughts that are extremely fine-grained, down to the scale of seconds, or nanoseconds. It is implausible, however, that we can place each such fine-grained temporal thought into a one-to-one correspondence with some similarly fine-grained attitude. The main problem is that we can't differentiate degrees of anticipation to the same extent. Can one really have a greater degree of anticipation for an event in a second, as opposed to one in two seconds? What about nanoseconds? It seems doubtful. Attitudes are just not that finely structured.

This position states clear roles for both emotion and anticipation as non-cognitive modes of subjective conscious experience, but the conclusion that anticipation can only exist by degree and that it is too coarse grained to function is inconsistent with the exceedingly fine-grained role of anticipation in existential threats to survival which occur in the conscious moment without any assumptions of the overall nature of time as a global or cosmological entity having any relevance to the immediate survival threat.

In this sense, the conscious moment, in both acute existential crisis and in deep mystical states IS timeless and consciousness is itself more generally an ongoing quantum of the present, which does not itself change but rather local conditions change as they pass in and out of our experience. This leads potentially to a deep correspondence between conscious timelessness and cosmological timelessness as complements of one another.

Other theories of agency treat it rather as a systems theoretic complementation to the physical universe.

Karen Barad (2007) in "Meeting the Universe Halfway: Quantum Physics and the Entanglement of Matter and Meaning", describes agential realism as a theory in which the universe comprises phenomena which are "the ontological inseparability of intra-acting agencies". "Intra-action", coined by Barad expresses an important challenge to individualist metaphysics. Phenomena or objects do not precede their interaction, rather, 'objects' emerge through particular intra-actions. Thus, apparatuses, which produce phenomena, are not assemblages of humans and nonhumans (as in actor-network theory). Rather, they are the condition of possibility of 'humans' and 'non-humans', not merely as ideational concepts, but in their materiality.

Her publication brief expresses it thus:

Intra-activity is an inexhaustible dynamism that configures and reconfigures relations of space-time-matter. In explaining intra-activity, Barad reveals questions about how nature and culture interact and change over time to be fundamentally misguided. And she reframes understanding of the nature of scientific and political practices and their "interrelationship." Thus she pays particular attention to the responsible practice of science, and she emphasizes changes in the understanding of political practices, critically reworking Judith Butler's influential theory of performativity.

I am concerned that this is a philosophical/metaphysical argument which poses a complementarity between quantum physics as an interactive process and human social and political discourse, marginalising the individual subject as a systems cipher. What meaning is there to subjective consciousness as a complement to the objective universe, individual insight, enlightenment, moksha or the cosmic mind, if the complement is based on political discourse, rather than empirical experience? On the other hand this is precisely what Symbiotic Existential Cosmology does in invoking an 'animistic' process of mutual affirmation socially to empirically establish subjective consciousness volition has efficacy over the physical universe, before investigating the role fo the physical brain in this process.

A second work by Scott Kelso and David Engström (2006) "The Complementary Nature" provides a complementary account of what they describe as "coordination dynamics" (Kelso 2013), within which complementarity is rooted:

The division of our world (natural and social) into distinct contraries or opposites has become almost universal practice in most fields of human endeavor and inquiry, including science. Undeniably, imposing such divisions on space and time, wave and particle, order and chaos, action and perception, or organism and environment have enabled significant progress in our scientific understanding of these separate domains. However, understanding based on separation or contraries is fundamentally limited, as is powerfully demonstrated by modern physics, biology and neuroscience. Coordination dynamics describes how coordinated patterns form and transform within and between parts of a given system. Core concepts, developed at length in the book, include self-organization, pattern dynamics, multifunctionality and functional equivalence, and information flow.

In the 1960's, general systems theory sought the goal of a common pattern and process, consonant with Ilya Prigogine's non-equilibrium thermodynamics of living systems, Hermann Haken's synergetics about self-organized coherence, Francisco Varela's (1972) autopoiesis, and Stuart Kauffman's (1986, 1993) autocatalysis. This means that coordination dynamics is attempting to treat physical, biological and even social systems on the same systems footing invoking a transformative continuity between processes which are isolated from one another and those in which coordinated interaction is derived from more generalised laws. However, in doing so, coordination dynamics remains an objective description of reality that does not seek to explain the hard problem of the fundamental nature of subjective consciousness, just the interactive properties of neuronal self-organisation as functional information:

Neuronal connections in the brain are an effective medium that nature has provided through the mechanisms of self-organization and natural selection. But the important concept here, as these simple experiments on people reveal, is biologically relevant

information. Such functional information can be conveyed by local connections and between distant areas, both by two-way interactions. In this capacity, local~global and integration~segregation are two of the key complementary pairs of coordination dynamics.

So how does coordination dynamics explain all these phenomena? And what are the implications of this different view of the brain for the complementary nature? The empirical data suggest that integration (pure coordination) and segregation (no coordination) in both brain and behavior may be viewed as polar, idealized extremes and that the key to understanding lies in the dynamical interplay of integration~segregation tendencies. As a candidate science of the complementary nature, coordination dynamics must minimally be able to explain both polarized complementary aspects and all that falls in between them.

The book cites a series of complements and a general relation:

Heterogeneity~Homogeneity, Oscillation~Rhythm and Coupling~Uncoupling and summarises them in a General process equation $\dot{c}v = f(cv, cp, f)$, where the rate of change of the coordination variable, cv , is a function f of three basic factors: the momentary value of the coordination variable cv itself; one or more control parameters cp ; and noisy fluctuations, F . Recall that coordination variables capture the functional nature of behavioral patterns. Such coordination variables can be quite abstract in that they can characterize coordination among the same and different kinds of elements and processes (homogeneous~heterogeneous).

Key here is the fact that these capture only the functional nature of behavioural patterns, not subjective consciousness. This approach is similar to that of autopoiesis (Maturana & Varela 1972) in that it provides a complementary objective description of physical and mental phenomena as complementary views of reality described by systems analysis without explaining the hard problem of subjective conscious experience.

Scott Kelso's work has also become the basis of more wide ranging explorations. Brian Josephson (2019) in "The Physics of Mind and Thought" utilises biosemiotics to provide a possible explanation of quantum measurement:

Regular physics is unsatisfactory in that it fails to take into consideration phenomena relating to mind and meaning, whereas on the other side of the cultural divide such constructs have been studied in detail. ... On the other side of the cultural divide, there is the fundamental idea of a sign, the study of which originated in the semiotic concepts developed in the nineteenth century by Charles Sanders Peirce, more recently taken up by biologists, thereby founding the subject of biosemiotics (Hoffmeyer 2008 a, b). Semiotics emphasises the role of interpretation, a process connecting signs with corresponding objects, or more generally mediation, a process involving situations where a third entity influences the relationship between two others. Such mechanisms play a key role in biology, and one that is essential for effective biological function.

Sign use, as originally argued by Peirce and subsequently developed by Deacon (1998) and by Favareau (2015), is of three types, iconic, indexical, and symbolic. The first two types of sign involve entities in the immediate environment, but symbolic use, which now appears to be confined to human beings, can involve manipulations concerning entities absent from the immediate environment, which faculty is attributed by Deacon to a human ability to avoid being too involved in the current situation during mental activity. This can be understood in terms of memory mechanisms that can, as it were, hold on to signs so as to be able to act systematically with them, and thereby develop 'games' such as mathematics.

The basic problem with quantum mechanics is that a person's decision as to what aspect of nature to observe can have real consequences, and it is unclear how such mental activity can be integrated with traditional physics; we cannot simply leave out the observer. A thesis in the above has been that semiotics (sign theory) will play a central role in such a future integrated physics, a basic task for such a future physics being that of bridging the gap between signs and the phenomena addressed by current physics, thereby arriving at an integrated point of view. A similar situation arises in conventional science, where a gap of this kind exists between fundamental physics and biology, one that can be bridged taking due account of a succession of levels, utilising a range of specialised approaches to deal with these.

Josephson (2019) in "The Physics of Mind and Thought" explores using biosemiotics to integrate physical cosmology with mind and meaning:

Regular physics is unsatisfactory in that it fails to take into consideration phenomena relating to mind and meaning, whereas on the other side of the cultural divide such constructs have been studied in detail. This paper discusses a possible synthesis of the two perspectives. Crucial is the way systems realising mental function can develop step by step on the basis of the scaffolding mechanisms of Hoffmeyer (2008 a, b), in a way that can be clarified by consideration of the phenomenon of language. Taking into account such constructs, aspects of which are apparent even with simple systems such as acoustically excited water, as with cymatics, potentially opens up a window into a world of mentality excluded from conventional physics as a result of the primary focus of the latter on the matter-like aspect of reality.

Josephson (2021) seeks to extend the complementation of quantum physics with socio-political systems of Barad, to invert the usual "theory of everything" approach to particle cosmology by treating it as an expression of goal seeking agents. He notes that both Bohm's notion of the implicate order and mind-like processes have been invoked:

In the following a more explicit picture is proposed, based on the existence of parallels between spontaneously fluctuating equilibrium states and life processes. Focus on the processes of natural language suggests a picture involving an evolving ensemble of experts, each with its own goals but nevertheless acting in harmony with each other. The details of how such an ensemble might function and evolve can translate into aspects of the world of fundamental physics such as symmetry and symmetry breaking, and can be expected to be the source of explicit models. This picture differs from that of regular physics in that goal-directedness has an important role to play, contrasting with that of the conventional view which implies a meaningless universe.

Josephson & Majumdar (2021) extend this, invoking Wheeler's notion that physical reality may be manifest through participating conscious observers through quantum measurement to use nonlinear dynamics, taking into account biological factors:

The constraint that structures that develop should have biological value is shown to be able to account naturally for many features of the quantum domain, thus providing an alternative paradigm to the conventional 'theory of everything' one, which has over time become problematic. For the future, detailed investigation of nonlinear dynamics along the lines discussed here is likely to be more fruitful in regard to the problem of understanding nature than continuing current attempts to tweak 'theories of everything' to fit.

Majumdar & Josephson (2020) formulate physics using system dynamics of self-selected fluctuations and correlations in a fundamental \odot field:

Instead of the traditional reductionist method of looking at phenomena in nature, we look at how the interplay of symmetry breaking and entanglement of subsystems within this unified field leads to entropic complexification – which appears as the fundamental interactions and particles. This complexification optimizes system configurations to facilitate energy dissipation. The fluctuations in the background field encode laws for phenomena based on the stability, recurrence and patterns of these fluctuations.

Chris Nunn: Go down the 'timelessness' route and you end up with some picture like Julian Barbour's path. The answer to this paradox could perhaps be that temporal extension *is* (proto)consciousness,

Chris King: I have two complementary views of conscious experience that overlap, just like the relativistic and quantum descriptions.

One is temporal and is our reckless journey through the multiverse, looking through our blind eye, as Nelson did at the signal to retreat in the Battle of Copenhagen, creating history for good or ill as we speak. That's the "quantum consciousness IS uncertainty" vision.

The other is eternal relativistic timelessness, in which everything that we have been and will be is laid out, looking from sideways on in space-time from alpha to Omega, as "a thing already achieved" as Maria Sabina said of her mushroom experiences. This doesn't mean everything is determined or teleological, but it's the view after all the transactional handshaking has taken place, of the great trip we and everyone took, so we can look on it from far off, perceiving as the compassionate, eternal consciousness we actually are. But Omega, as I have said is not the end point. The consummation of existence is not Omega but the interactive Sigma – Paradise on the cosmic equator in space time.

Chris Nunn: But isn't 'consciousness' a correlate at least of what *removes* uncertainty. The two concepts seem to lie at opposite poles of the *same* truth and it looks like we need some happy mean. And an idea of temporo-spatial evolution can provide one – 'threads' of consciousness-associated time getting woven into ever more elaborate forms.

Chris King: Consciousness is here to mitigate, mediate, or utilise uncertainty as the need may be. However uncertainty is not the opposite of consciousness, but an inside out view of the same thing.

It also depends on our frame of reference. If we are looking at brain states, if there is no uncertainty in our brain state then we are a zombie, or a robot. There is no role for subjective consciousness at all. So from the physical perspective the brain state needs to enter an uncertain state for subjective consciousness to be able to intervene and affect outcomes. From the subjective perspective this is the opposite, because we cease being zombies and become conscious agents, removing uncertainty from the world as we act by creating real history.

But again centrally the uncertain states that are seriously going to threaten our survival in the wild are things like a snake strike. This is all caught up in the uncertainty of the way circumstances play out. We can try to do "good

hunting” and take the path we think the snake is less likely to be on, but the snake is going to play likewise to hunt me and take the path that I would least expect. These environmental problems are (a) computationally intractable and (b) quantum idiosyncratic, motivated by live volition and sheer coincidence. The same is true in modern society with other humans and traffic and hurricanes and diseases all playing wildcard elements. So there is a deep correspondence between quantum uncertainty on all scales and conscious anticipation. Nelson knew he was looking through his blind eye and that it would change the course of history. It did. But the terrible acid test is that this looks like consciousness is staring right into the entanglement and fishing for a collapse state by some kind of transactional hand-shaking between past and future to anticipate the cat remaining alive.

Yes there are situations where we execute a well designed plan and things go like clockwork, but even in these situations there are multiple sequential non-IID situations about just how we handle a process and the uncertainties that inevitably lead to uncertainty. The brain has worked out how to do this seamlessly because operating at the edge of chaos allows the uncertain regime and the determinate boundary conditions of consciousness to coexist in the dynamical system and for bifurcations into and out of uncertainty.

The real evolutionary victory of the conscious brain happened at the eucaryote endosymbiosis when the excitable membrane became a sensory and social communication dynamic in self-feedback. This is where we can look for the secret of this existential anticipation dynamic because the brain is just a very advanced society of social amoeboid flagellates locked in “psychic” symbiosis through brain resonances, so to speak. The result is that we do not understand uncertainty or what its deep link to us is. We think of it as randomness but all randomness ultimately is a secondary product of quantum uncertainty and it's obvious that a multiplicity of entanglements lead to a vast network of correlations. The randomness only appears as we approach the classical Born rule situation by travelling down an IID sequence. So the paradox becomes uncertainty = free will.

Chris Nunn: There are two separate, albeit inter-related, issues here. One is neural deterministic chaos with its pseudo-random outcomes and unpredictability in anything other than the very short term, plus its capacity for harbouring strange attractors (‘memories’). The other is the huge question, albeit one that's often ignored, as to whether the entire ‘quanglement’ realm is similarly constituted. There are major empirical problems with supposing that quantum EM fields don't embody pseudo-randomness and associated universal structure, though ones constrained by the Higgs field may be more localised (the relevant experiments haven't been done yet).

Chris King: This is the nub. Tuneable chaotic neurodynamics as Freeman emphasised, is not classical deterministic chaos because it's the dynamics of quantum structures from the molecule up, so the use of edge-of-chaos in neurodynamics is not deterministic dynamical chaos, as in a mathematical system like the logistic iteration or the Lorenz flow. These are classical ideals and are not realistic in relation to the conscious brain.

The key is the point you are making about whether, for example phase coherence in distinguishing conscious states from subconscious, that Pribram emphasised, is more than just an analogy with quantum measurement and is something fundamental about quantum measurement and entanglement. I think it is and it is because the superficial evidence is that the brain is deriving an anticipatory advantage in environmental uncertainty from using phase angle coherence sampling at the edge-of-dynamical chaos. The only way this makes sense is that its advantageous to survival as a form of quantum anticipation, despite trading off potentially noisy disruption of classical causality.

Neurodynamics is a non IID-quantum process whose contexts are continually changing, so no approach to the Born interpretation occurs, so the whole thing needs to be treated quantum theoretically, which is beyond the scope of current science. The neuroscience area is still stuck in the classical paradigm, so you refer to deterministic chaos but it isn't classical. We just simply haven't caught up conceptually with the entangled quantum universe we are consciously existing in. The fallacy lies in looking for isolated phenomena like the ion channel where we can be convinced we are at the quantum level and accepting only those as quantum effects and treating all other aspects of neurodynamics as classical by default.

My take is that Pribram's analogy is an actuality. This idea of quantum coherence measurement is reinforced by the fact that individual action potentials are phase correlated with the local continuous field potentials in a hand-shaking resonance, so the EEG is not just an artefact of action potential averages, but a genuine wave function. Thus the brain can seriously be looked at as a massively parallel quantum measurement process, where EEG modes are analogous to, or actually are, quantum “excitons”.

Chris Nunn: I like to think that the conversion process can be viewed as the endowment of abstractions with temporal extension. You might object that one could equally well say 'spatial extension' but I don't think that would be correct because spatial extension (i.e. 'position') is already present in the 'abstraction' (i.e. the wave function), whereas temporal position isn't.

Chris King: I agree about temporal extension, but I would add that the wave function, if you are referring to the quantum wave function, is both spatially and temporally extended, as in the Feynman and transactional descriptions, and vastly temporally extended into both the past and future to put it mildly.

Chris Nunn: There's much confusion about 'free will'. It may best be regarded as the capacity of volitional consciousness to influence behaviour and its own future content, leaving out questions about the determinants of volitional consciousness. I agree that it is not fully determined by purely neural constraints, though social constraints on it are very significant. To a large extent true 'freedom' may depend on an interplay between neural and social constraints, perhaps with some input from both (pseudo) randomness and universal 'quanglement' structure.

Chris King: Absolutely!

Chris Nunn: I think of Freeman neurodynamics in terms of 'landscapes' in classical dynamic state space. True Freeman (and Vitiello) tried to apply the maths of QFT to these but, so far as I know, this was mainly because of the need to cope with almost infinite dimensionality. The advantage of staying classical is that it provides a ready explanation of a wide range of properties, especially sleep which is all about smoothing out excessive landscape 'rutting' along with fitting new attractors into existing landscapes.

Chris King: You are absolutely right here. This is the way he did it in great detail using differential equations modelling excitatory and inhibitory feedback, generating phenomena of classical chaos and it is beautifully informative of transitions from high energy chaos into existing, or even new attractors from learning.

The complications starts to set in when we go from the classical model to actual EEG potentials, where we are measuring a classical signal of discretely sampled voltages in a time series, which we conceive of as continuous potential variations in the scalp, or more deeply on the cortical surface. Qasim et al. (2021) have shown that action potentials are phase responsive to the local continuous field potential which people in turn believe is a tissue average of the effects of the same action potentials, so we have a particular kind of discrete-continuous feedback here which has the complementary characteristics we see in wave function reduction to the particle. I'm not saying they are the same, but that they both have a discrete continuous complementarity based on phase which is exactly what the uncertainty principle says in terms of counting wave beats to determine time uncertainty of the energy.

And without saying ion channels are the only quantum process, individual action potentials are only a step of scale away from the ion channel because threshold tuning in the neuron is a form of self-organised criticality that in threshold can make the action potential sensitive to the ion channel.

Chris Nunn: Any influence of quantum coherence on these landscape features is likely to depend on structured modification of classical dynamic timings, according to this picture.

Chris King: So this is where I think the classical description you are advancing starts to break down. We don't actually have a classical picture, we have a classical model and a biological picture and the biological picture is a fractal process with scale handshaking. Moreover isolating the ion channel as the only plausible quantum level is wrong because the whole picture is one fractal reverberating process which is as far from IID-convergence to the classical (by independent identically-distributed quantum measurements) as living thermodynamics is from equilibrium.

So the answer to the above is that it is wrong to think of the process on one level as classical in a way we can conceive of e.g. thinking of the neuron in terms of classical differential equations and then assume its classical and say any quantum effects are going to have to prove themselves and possibly complicate the classical process. The reality is the whole thing evolved as a reverberating quantum system and things on a larger scale that we think of as classical are actually "inflated" quantum processes throughout, particularly given the butterfly effect, because the failure to converge to the classical means everything is not causally localised in the way we are anticipating.

This is a very hard call for experimental and theoretical science because, if non-IID processes do formally fail to converge to the classical overall, we haven't even started to embark on the scientific journey of how to make sense of this. This is why I think proving classical causal brain closure is scientifically impossible, so that the simple affirmation of subjective conscious physical volition carries far more analytical power and evidential weight and overturns physical materialism at the outset.

Chris Nunn: The way I'd see this is that phase coherence, whether classical or quantum, mediates attachment of memory-dependent meaning to information. The meaning is represented in terms of ever evolving topological structures, ones that can usefully be thought of as woven tapestries, which become conscious if temporal looping allows memories of the occurrence of the meanings. Any 'anticipation' ('Bayesian brain' manifestations) would usually be a function of indirect, long term classical loopings usually referred to as 'learning'. 'Quantum anticipations' would have a secondary role, dependent on effects of entanglement 'structure' on classical neural coherence timings, that could be responsible for a range of 'psi' phenomena.

Chris King: All these things may be true as well, but the difference with edge-of-chaos quantum dynamics is that all these processes you are describing are now boundary condition filters on root uncertainty, rather than classical causalities, so depending on how robust they are in a given context they can dominate overall in some situations and are manifestly incomplete influences in others.

Chris Nunn: Agreed, though we do need to retain conceptual distinctions for many purposes. Like the weather out there, lots of neural dynamics are mainly classical. They may be a lot more sensitive than the weather to any influences of quanglement structure, but it's still a limited influence.

Chris King: I think we need to replace "mainly classical" with "formative classical boundary conditions on uncertainty".

Chris Nunn: Agreed there's a lot to be said for musical analogies, but it's a music that we experience synaesthetically - as Scriabin, for instance, saw shapes in sounds. Your view of EEG modes has a lot in common with Johnjoe McFadden's 'cemi-field' theory (McFadden 2020). I prefer to think of them as creating form in the structure of time - and time, of course, is a constraint on quantum particles - not itself a wave function derivable 'particle'.

Chris King: That's very complicated. The way I enter the nierika on mushrooms is a synaesthetic resonance between rushing chirping sounds and the visual patterns before me and then as I'm "listening" to it all, it expands into vistas that I can see in the corner of my eye with exquisite observational detail, and then if I let go, I fall into the synaesthesia and then that's down the moksha rabbit hole until I come catapulting out at some later point and realise "what the hell just happened to me?" and recollect the full impact of the journey I have taken. While this IS a musical analogy it's also a cosmological reality, just like the particle trails in the LHC are. Whatever time is in this picture is still in the process of being elucidated, as the paradoxes of quantum gravity intimate.

Chris Nunn: Wouldn't it be more correct to say that wave functions don't own inherent spatio-temporal 'extension', except universally, and via incorporation of a potentiality for defining spatial localisations?

Chris King: I really wanted to finish with the transactional interpretation, so here it is. Both the Feynman description of virtual particle exchanges in QED and the transactional interpretation of real particle exchanges involve special relativistic hand-shaking between past emitters and future absorbers. Looked at from the transactional viewpoint, before we open the cat's box there is a web of past-future handshaking transactions. Somehow, as we open the box, this web is decomposed in some kind of non-linear interaction and as we look inside, there is one emitter and one absorber and if the latter was in the geiger counter, the cat is no more. But this process doesn't go from past to present to future. It's transversal to elapsing time, which is why I called it "trans-causality" in 1985 when I wrote "Dual-time Supercausality".

This is the jewel in the lotus that is yet to teach us where quasi/pseudo-randomness and randomness both meet their match in the partially collapsing entanglement. The key point is it spans space-time as we know it and the process has paradoxical constraints. It has to look quasi-random in terms of the Born interpretation at one end, but it has to manifest precise correlations between each of the entangled components at the other. That is the second lesson after we sing the musical hymns to reality and take another long journey into the unknown!

Chris Nunn: Looks like a very nice concept resonance! The only additional point I'd like to make is that Qasim et al's finding probably relates to the largest scale of a (pseudo) fractal structure of brain dynamics in which the smallest scales relate to neuronal contributions to dendritic plexi, intermediate scales to astrocytic 'domains' and largest scales to EEG fields generally. Anyhow, I suppose next step is how to test all this in a way that has some chance of convincing neuropsychologists generally. The fate of Daryl Bem (2012, 2016) and others 'pre-sponse' ('pre-sentiment') findings shows this isn't easy. An example of something that might work better is that our ideas (along with John Jay Kineman's 'holonic' concept) would seem to predict something very like Rupert Sheldrake's (1981) formative causation, at least in relation to learning by brains and possibly generally. Shouldn't be too hard to convincingly test that if someone would provide the resources. What do you think? Any other suggestions?

Chris King: I have an issue with Sheldrake's morphic resonance (formative causation). This to me is causally what RNA would be like if the polymerisation were exothermic – i.e. it would become an irreversible clunker. I had a conversation with Rupert in the 1980s and tried to point out that the leading edge issue is creative insight, not morphic resonance. It's a space-time problem to which anticipation is key not just spatial replication. It's getting the first instance of an idea that is formative, not replication ad nauseam. The idea that this replicates afterwards is not explaining the creative source and it leads to a teleological fait accompli. Thus I think the notion is a hopeful evolutionary monster.

Chris Nunn: That's one way of looking at it. I'd see 'formative causation' as analogous to neural learning but embodied in a quanglement landscape, not a neural dynamic state space one. Just as with neural learning, the relevant quanglement feature can be expected to 'deepen' with repetition. The assumption here is that there is feedback from classical dynamics to quantum field 'structure' but this is implicit in all our models.

Chris King: That's a good insight! I agree basically. I spent the day going over Penrose and Hameroff which I do think is off the beam, so that's how I stated my summary, but it made me think again about Penrose's space-time blistering idea and yes he is also saying uncertainty is not random at least in his confined context to the microtubules so it does fit with a kind of quanglement learning process, in particular the idea that at least some forms of entanglement are non-random and might be connected to mind states.

The Diverse States of Subjective Consciousness

A key issue in this discussion, particularly in regard to the materialist emphasis of neuroscience, is the fact that there are diverse states of conscious experience that extend far beyond and deeper into our awareness than the states of everyday experience of the world around us. Those who spend virtually all their living existence only relating to the everyday waking state can easily slip into identifying subjective consciousness with merely being an internal model of physical reality around them and then succumb to mind-brain identity, or exclusively materialistic conceptions of subjective consciousness as a brain mechanism.

These include:

- (a) **Dreams** particularly the richer end of the REM spectrum of states, including lucid and prescient dreams.
- (b) **Psychedelic experiences**, which 'reveal' internal realities, from kaleidoscopic geometric visions to whole scenes and encounters, generally of a radically different nature to those of dreams, meditation on its own and ordinary consciousness. These constitute the traditional sacramental routes to entheogenic realisation, or moksha.
- (c) **Dissociative experiences** such as induced in different ways by salvinorin-A and the anaesthetic ketamine, which differ from psychedelics in both their mechanism and their experiential character.
- (d) **Meditative and contemplative** states of sensory withdrawal and ego loss. These are the traditional non-sacramental routes to mystical union, moksha and satori, which complement the sacramental routes in (b).
- (e) **Psychic and parapsychological** experiences, including (1) precognition, (2) prescience & déjà vu, (3) uncanny unexplained coincidences, (4) telepathy, and (5) psychokinesis.
- (f) **Near death experiences NDEs** (Grayson & Flynn 1984, Groff 1988, Borjigin et al 2013, Parnia et al. 2023), which may accompany cardiac arrest, anaesthesia and non-life-threatening states; and **out of body experiences OBEs** (Monroe 1989), where a person on the border of sleep, an NDE, or in a non-ordinary conscious state observes their own body from without, in a disembodied state.

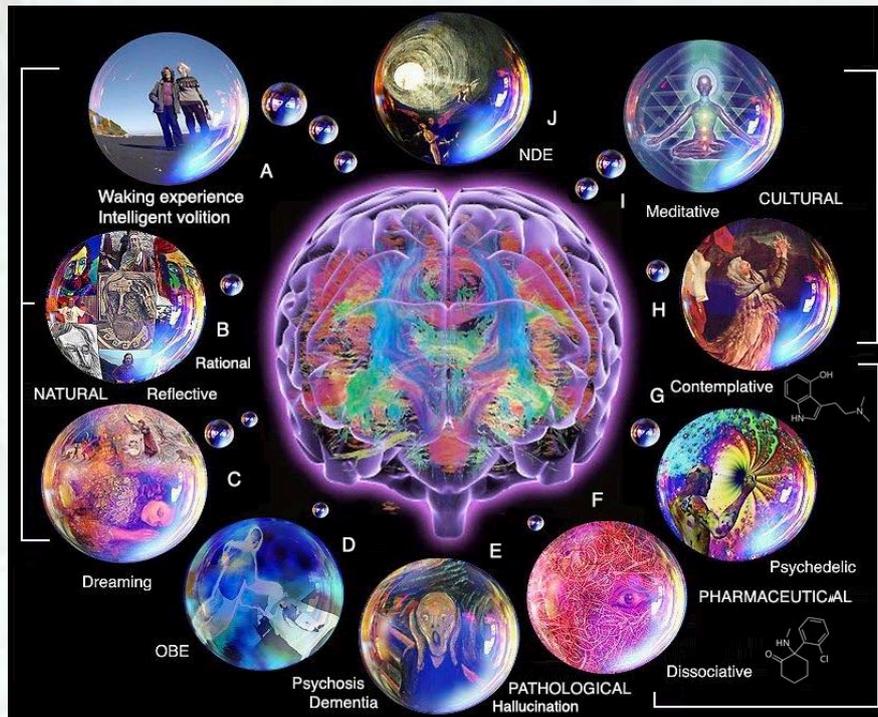

Fig 107: The sheer diversity of conscious mental states need exploration in their own right without a priori assumptions.

This belies the complexity and depth of the problem of consciousness because there are a variety of states of non-ordinary consciousness, which are neither imaginary, nor simply hallucinatory, nor are they just random uncoordinated phenomena, but are perceived as veridical experiences having the same, or qualitatively similar reality value, to our experiences of the world around us.

Moksha⁴⁶ means release from the cycle of birth and death in this life in the sense of experiencing and realising the conscious cosmic unity that transcends the physically mortal condition.

Dreaming states tend to be the most fully fledged experiences of non-ordinary reality human being experience although ephemeral in that they can only be recalled during waking. They are also veridical sentient experiences that are highly unpredictable, creative, and although they may reflect recent experiences may also hint at future experiences that come true later, hinting a deep time-spanning reality underlying existential consciousness. This appears to go far beyond the cited functional roles of REM and deep sleep in memory. Lucid dreaming states, although difficult to initiate and unstable either to immediate awakening by activating the reticular activating system or subject to a false awakening and reversion to the normal REM state, can enable the conscious observer to experience an often very exotic mental state in real time by recognising they are dreaming during the dream state.

Psychedelic and **dissociative** experiences are non-ordinary waking states that, by contrast with dreaming sleep, can be experienced and interrogated consciously. We have already discussed psychedelic experiences extensively throughout this work. Psychedelic states have particularly striking attributes, especially when combined with meditative withdrawal, characterised by “ultimate reality” and types of abstract perceptual experience having intense reality value radically different from any other kinds of experience. These are not hallucinations and their nature needs a great deal of further subjective exploration to begin to fully fathom.

Meditative experiences, although more controlled and tending more to mindfulness and compassion likewise stand in the Eastern tradition as a central route to union with cosmic reality exemplified in the union of Brahman and atman.

Parapsychological experiences, which are the orphans of materialistic science, are perceived as common place by many individuals and surveys indicate a degree of statistical support (Cardena 2018, Wardell 2019, Giroladini 1991). Some of these may be associated with deep properties of the quantum universe, hinted at in the Feynman formalism, weak quantum measurement and the transactional interpretation. These diverse forms of subjective experience

⁴⁶ *moksha* – derived from the Sanskrit word muc (“to free”), the term moksha literally means freedom from samsara (existential illusion). This concept of liberation or release is shared by a wide spectrum of religious traditions, including Hinduism, Buddhism, and Jainism.

present a deep and complex domain of subjective discovery, which has barely been tapped and emphasises the inadequacy of assuming a physically materialistic view, which diminishes the authenticity of everyday experience to be merely an epiphenomenal internal brain model and assigns all forms of non-ordinary conscious experience to delusory, imaginary, confabulated, stochastic, or hallucinatory status.

The psychedelic psychotherapist Stanislav Groff (1988) gives an insight into this wider “geography” of non-ordinary conscious states surrounding the realms of traditional perennial philosophy, in his notion of the territories of holotropy surrounding those of traditional religious cosmologies:

The hylotropic, or matter-oriented, mode of consciousness is the term I am using for the normal, everyday experience of consensus reality. The holotropic mode of consciousness, or consciousness aiming toward wholeness and totality of existence, characterizes certain nonordinary psychological states, such as meditative, mystical, or psychedelic experiences. It can also be observed in many spontaneously occurring episodes referred to as psychotic by contemporary psychiatry.

In the hylotropic mode of consciousness, we experience only a limited and specific segment of the phenomenal world or consensus reality from one moment to another. The nature and scope of this experiential fragment of reality is quite unambiguously defined by our spatial and temporal coordinates in the phenomenal world, the anatomical and physiological limitations of our sensory organs, and the physical characteristics of the environment.

In the holotropic mode of consciousness, it is possible to reach, in addition, all the remaining aspects of existence. These include not only access to one's biological, psychological, social, racial, and spiritual history and the past, present, and future of the entire phenomenal world, but access to many other levels and domains of reality described by the great mystical traditions of the world. Comparative study of mystical literature shows that most of these systems seem to agree on a complex, layered, and hierarchical model of reality that includes phenomenal as well as transphenomenal aspects of existence.

The gross experiential realm reflects the world of ordinary waking consciousness and consensus reality based on the evidence of the sensory organs. The corresponding worldview and way of being in the world is limited to information derived from the physical body and the material world, to linear causality as the only connecting principle, and to Newtonian understanding of space and time. Many systems of perennial philosophy have identified and explored, in addition, several transphenomenal levels or realms of existence, usually referred to as subtle, causal, and ultimate or absolute.

Both the subtle and the causal levels can be further subdivided into lower and higher. The lower subtle, or astral-psychic, level contains traditionally out-of-body experiences, astral travel, occult and psychic phenomena (precognition, clairvoyance, psychokinesis), auras, and similar experiences. The higher subtle level comprises archetypal forms of deities, supreme presences and spiritual guides, experiences of divine inspiration, visions of light, and audible illuminations. ... The lower causal level is the realm of savikalpa samadhi, the final God, creator of all the realms, the audible light of bija mantra the source of all individual deities. The higher causal realm is characterized by ultimate transcendence and release into boundless radiance, or nirvikalpa samadhi. On this level, there is no subject or object, no self or god, only formless consciousness as such. On the level of the Absolute, consciousness awakens to its original condition and suchness, which is also suchness of all of existence gross, subtle, and causal.

Savikalpa samadhi is sometimes described as the state in which the yogi's consciousness temporarily dissolves into Brahman. Depending on the yogic tradition, savikalpa is either the second or third highest level of samadhi.

*The observations from modern consciousness research with or without psychedelic drugs bring, in general, strong supportive evidence for this understanding of reality. However, in specific details, **the cartography of consciousness found in perennial philosophy would have to be extended and modified to fit the findings of experimental psychiatry and the new experiential psychotherapies.** In the following text, I will attempt to outline a classification of transpersonal experiences that is based on the scheme of perennial philosophy, but incorporates, at the same time, the findings of modern scientific research.*

*To create a transpersonal taxonomy that would reflect in an accurate and comprehensive way the introspective data and objective observations from modern consciousness research is not an easy task. **The spectrum of transpersonal experiences is not only extremely rich, ramified, and variegated, but includes levels of reality governed by laws and principles that are different from those that rule ordinary reality. Many transpersonal experiences, being ineffable, elude adequate verbal description and occur on levels of reality where those very aspects that could ordinarily serve as principia divisionis, such as time, space, duality, and polarity, or linear causality, are transcended. The problem is further complicated by the holographic nature of consciousness and mutual interpenetration of its different levels and domains.***

This realm extends to both a unification with all life and with the ultimate reality of the Cosmos:

Transpersonal experiences which involve transcendence of spatial barriers suggest that the boundaries between the individual and the rest of the universe are not fixed and absolute. Under special circumstances, it is possible to identify experientially with anything in the universe, including the entire cosmos itself. Here belong the experiences of merging with another person into a state of dual unity or assuming another person's identity, of tuning into the consciousness of a specific group of people, or of expansion of one's consciousness to such an extent that it seems to encompass all of humanity. In a similar way, one can transcend the limits of the

specifically human experience and identify with the consciousness of animals, plants, or even inorganic objects and processes. In the extremes, it is possible to experience the consciousness of the entire biosphere, of our planet, or of the entire material universe.

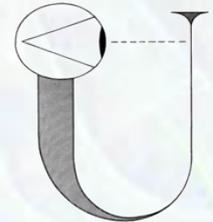

In some rare instances, an individual in the holotropic mode can have the experience of consciousness expanding to such an extent that it encompasses the totality of life on this planet, including all of humanity and the entire fauna and flora, from viruses and unicellular organisms to highly differentiated species. Instead of the ordinary identification with one living organism, this experience represents identification with life as a cosmic phenomenon.

Individuals experiencing identification with Cosmic Consciousness have the feeling of encompassing the totality of existence and reaching the Reality underlying all realities. They sense beyond any doubt that they are in connection with the supreme and ultimate principle of Being. This principle is the only real mystery; once its existence is accepted, everything else can be explained from it and understood. The illusions of matter, space, and time, as well as an infinite number of other forms and levels of reality, have been completely transcended and reduced to this one mysterious principle as their common source and denominator.

This experience is boundless, unfathomable, and ineffable. Verbal communication and the very symbolic structure of our language appear to be a ridiculously inadequate means to capture it and convey its qualities. Our phenomenal world and everything that we experience in the ordinary states of consciousness fades away in the light of this supreme awareness as limited, illusory, and idiosyncratic aspects of this one Reality. This principle is clearly beyond any rational comprehension, and yet even a short experiential exposure to it satisfies all the subjects intellectual and philosophical craving. All the questions that have ever been asked seem to be answered, or there is no need to ask any questions at all.

This emphasises the position already expressed in the introduction that, while brain states may be a necessary condition for human conscious experiences, they are not a sufficient condition and the primacy of the conscious condition introduces a cosmological paradox. All our experience of the world is exclusively through our conscious perception of it and yet we are bound to accept the reality of the external universe for our own conscious survival as biological organisms and to negotiate the affairs of the world, but we simply don't know the existential status of the universe is actually able to manifest in the absence of our conscious experience of it and the fact that we don't is critical to good cosmological design. So experiential reality including the source of our scientific description of it starts with consciousness and ends up with the universe, while biogenesis starts with cosmic symmetry-breaking and ends up with conscious organisms. That's the existential paradox.

Fig 108: Wheeler's universe as a self-excited circuit. The universe starts out right as the thin black line, then it grows and in time and gives rise to 'observer-participancy', which in turn imparts 'tangible reality' to even the earliest days of the universe.

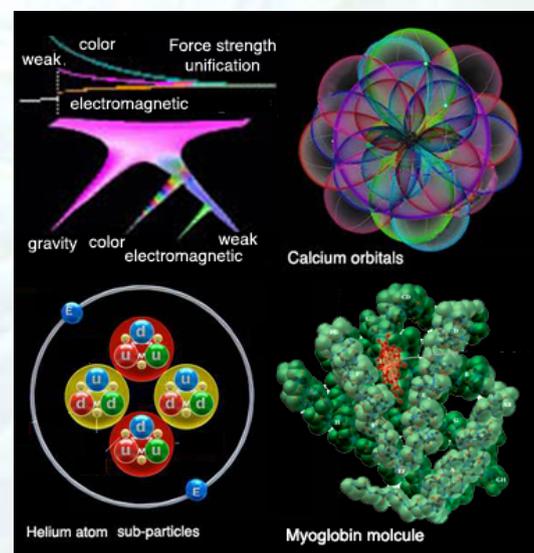

John Archibald Wheeler (1983) quotes as follows:

"An old legend describes a dialog between Abraham and Jehovah. Jehovah chides Abraham "You would not even exist if it were not for me!", who replies "Yes Lord that I know, but also You would not be known if it were not for me. In our time the participants in the dialog have changed. They are the universe and man". "How does quantum mechanics differ from what Bishop George Berkeley told us two centuries ago?:" "Esse est percipi" to be is to be perceived.

Insight, Agency, Uncertainty, Creativity, Karma, and Volition: Subjective Consciousness as a Quantum Climax

The following is an exploratory description based only on circumstantial evidence, to elucidate how subjective consciousness, through the environmental boundary conditions imposed by the neurodynamically active brain, may bring about the climax conscious cosmology of the sentient universe as we know and experience it. It is purely speculative, but is a test, if not a proof of principle about what we as subjectively conscious sentient beings, with autonomy of volitional will over our decision-making behaviour in the physical universe, are actually here doing.

Notwithstanding the apparent contradiction between quantum reality, occurring within space-time, and gravity, which is not renormalisable like the other forces, where, in general relativity, the curvature of space-time is functionally coupled to gravitation, quantum reality nevertheless appears to be a fundamental transition in cosmology that is not just confined to the vector boson

– colour, weak and electromagnetic forces. For example superstring theory is couched in terms of supersymmetry, in which each integral spin boson is paired to a half integral spin fermion and vice versa, balancing the negative vacuum contribution of the fermions against the positive contribution of the bosons, accompanied by string quantum excitations at the Planck scale. It thus becomes critical to understand the role of quantum reality in biological and particularly neurodynamic processes associated with subjective consciousness.

Fig 108a1: Cosmic symmetry-breaking and molecular fractality. Cosmic symmetry-breaking results in the four forces of nature, in which quarks bond in colour triplets to form protons and neutrons, to form atomic nuclei, with orbital electrons, forming atoms, which then bond in a succession of strong covalent and ionic and then cooperative weaker H-bonds and polarity bifurcations to form fractal molecular structures extending from individual molecules to tissues and organs.

Biogenesis and the evolution of complex life is clearly a consequence of the symmetry-breaking of the forces of nature. The generation of molecular matter and particularly organics in supernovae is generated by the tiered interaction of the strong and weak nuclear forces and electromagnetism under the collective influence of gravity to form some 100 atomic nuclei, atoms with orbital electrons and molecules.

This interaction supplied by free energy of solar radiation on the negentropic planetary surface, results in far from equilibrium thermodynamics giving rise to a complex edge-of-chaos dynamic molecular landscape in a phase transition, where cycles of anabolic polymerisation and catabolic denaturing become highly sensitive to varying “initial” conditions determined by the particular molecular concentrations of organic molecules forming prebiotic precursors of proteins and nucleic acids, as discussed in the [fractal biocosmology](#) section. The sheer diversity of organics in the Murchison chondrite, fig 53, illustrates this. This also requires polynucleotides to be marginally unstable thermodynamically, to avoid irreversible polymerisation, just as RNA is, thus requiring a sustained phase transition state to achieve replication.

These are not just structurally fractal as shown in the biocosmology section, but have fully fractal dynamics, as manifested in biological organisms. The unlimited emergent potential of such regimes has been vastly underestimated by the exclusive focus on attempting to find the “magic formula” that will immediately generate working polynucleotide and polypeptide systems as a mechanically defined system, rather than understanding the ecologically emergent potential of such systems as a whole.

Molecular systems, as experimentally explored and detected in experiments and in carbonaceous chondrites and our knowledge of molecular processes, quantum tunnelling in enzymes and superposition in protein folding indicate that such molecular systems involve quantum processes and constitute vastly more complex forms of three dimensional quantum spatio-temporal computing automata than the classical discrete examples of 1D and 2D [cellular automata](#) (CAs) familiar to mathematics. As I wrote this, q-bits for quantum computing have been generated on single molecules (Castelvecchi 2023).

Such CAs can be analysed in terms of chaos and order based on the proportion of live and dead cells and some of those at the edge of chaos such as the 1D system 110 and John Horton Conway’s 2D game of life take the form of universal computers where any Turing compatible process can be represented as a set of initial conditions which can then be computed by the CA’s universal rules. In a similar but vastly more complex quantum computing phenomenon free molecular interaction in molecular populations can give rise to living organisms in which genetically coded proteins can in turn generate excitable cells, and brains which are not only the most complex computational objects in the known universe, but are also subjectively conscious. CAs such as the game of life can generate both a computer CPU as a computational illustration, but also form free-living digital ecologies, in which initial conditions give rise systems of potentially unbounded digital complexity.

Molecular systems the early Earth, exceed the classical dynamics of the game of life in three ways: (1) They are three dimensional not two. (2) They are quantum systems exploiting both superposition and entanglement. (3) They are continuously redefining the rules of engagement because the molecules themselves are defining the “field” dynamics through their autocatalytic interactions on the early Earth, rich with organics in a variety of far-from equilibrium contexts, from lost city undersea vents to ponds and shorelines with heightened magnetic interactions prone to chiral selectivity provide a wide variety of geological contexts to form an “open set” of initial conditions generating a continuously evolving ecology of arbitrarily complex molecular progenotes as cooperatively interactive, far-from-equilibrium edge-of-chaos systems, under sustained phase-transition.

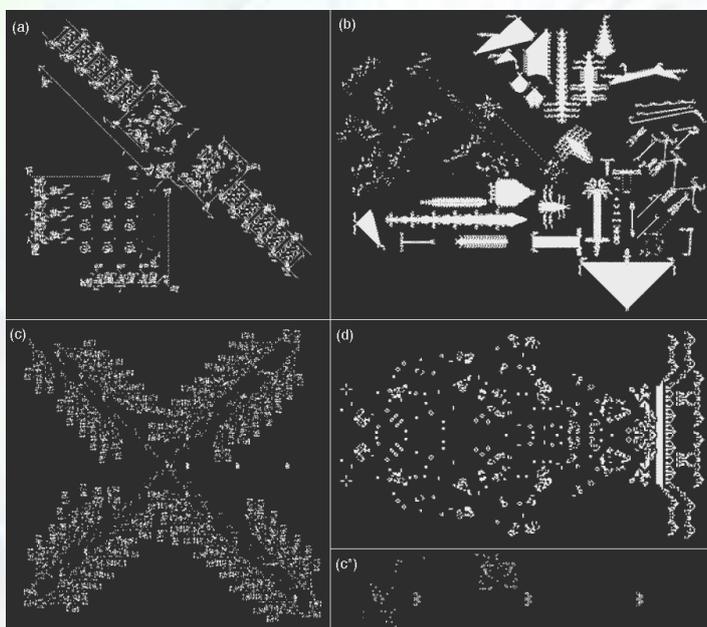

What is needed is a dedicated experimental program like the LHC, in the form of an organic molecular reactor that can generate phase transition systems with a variety of controllable molecular inputs, accompanied by free energy sources e.g. of simulated stellar radiation, spark discharge, lost city vent type chemical interfaces and magneto-chiral evaporating shorelines that can be sampled on a real time basis by automated gas chromatography and mass spectrometry as a tuned evolving system.

The laser, superconductivity and superfluidity are examples of highly coherent quantum systems, whose effects are evident at the macroscopic scale. The laser also demonstrates macroscopic multi-particle entanglement at ambient temperatures. The classical electromagnetic field also exhibits macroscopic quantum coherence. The most obvious example is the carrier signals for radio and TV, which satisfy Glauber's (1963) quantum description of coherence.

Quantum coherence has been shown to be equivalent to quantum entanglement in the sense that coherence can be faithfully described as entanglement, and conversely that each entanglement measure corresponds to a coherence measure (Tan & Jeong 2018). A common misconception of biological processes is that they are fundamentally classical in nature and that the law of mass action will prohibit quantum phenomena which will become thermodynamically

overwhelmed by interactions which will destroy any quantum coherence at the warm wet ambient biological temperatures of 25°C, but this is an unjustified conclusion, as we shall see.

Fig 108a2: The game of life consists of a 2-D rectangular field of cells updated by the rule that any cell with 2 or 3 live neighbours remains alive while one surrounded by 3 live cells also becomes alive. This results in a critical dynamic at the edge of discrete chaos where any grid of cells has the capacity to form a universal computer and/or reach unlimited scales of complexity. These are illustrated (a) in a simulation of a computational CPU, (b) in terms of a series of self-propagating organismoids, (c) by a disordered partially symmetric assembly generating a series of gliders, with fractal details inset in (c2) and (d) by a large glider acting as a generator for an ensuing slip-stream of clouds of persistently active cells.

Biology is rich with phenomena at the quantum level, which are essential to biological function.

Protein folding is a manifestation of quantum

computation. The protein folding problem is solved biologically through each molecule being effectively in a superposition of states which can use wave tunnelling to reach an optimal active conformation. Enzymes likewise invoke quantum tunnelling to enable transitions through their substrate's activation energy barrier to form the products, thus accelerating the reaction rate by orders of magnitude. Research confirms that the conscious brain can detect single photons and is able to amplify sensitivity given previous threshold input (Tinsley et al. 2016, Takeshita et al. 2017).

Quantum entanglement has been claimed to be behind the way migrating birds navigate in the magnetic field (Giachello et al. 2016, Paul et al. 2017, Hiscock et al. 2016, Gunther et al. 2018). When a spinach photosynthetic active centre absorbs a photon, it has also been suggested that the excitation's wave function performs a spatially parallel quantum computation, which enables the excitation to travel down the most efficient route to reach the chemical reaction site (Hildner et al. 2013, Romero et al. 2014), however photon absorption in photosynthetic bacteria involves pairs of excited proteins which enter into a superimposed vibrational state, in which one or the other becomes activated (Maiuri et al. 2018, Thyryhaug et al 2018, Duan et al. 2022) with excitons having ultra short time scales.

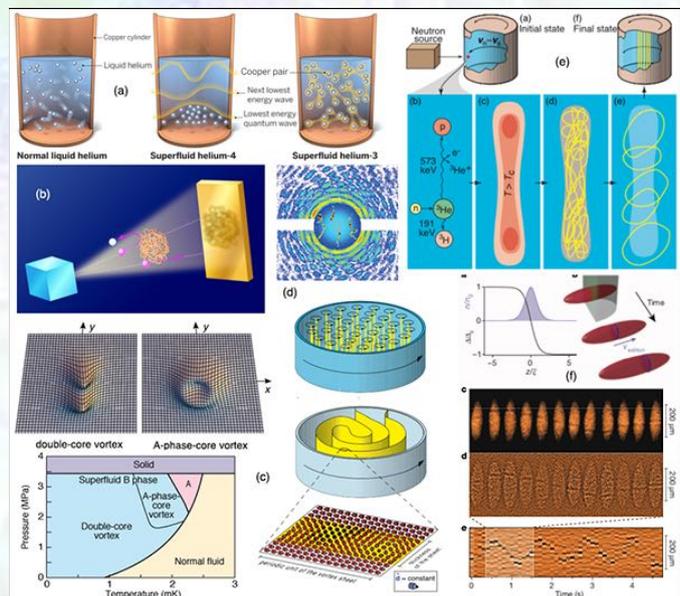

Danah Zohar (1990) in "The Quantum Self" has also drawn attention to ways in which quantum phenomena could arise in the brain, including the coherence states proposed by Herbert Frölich (1968, 1977, 1983, 1988) which have received some experimental support (Katona et al. 2015), particularly in systems driven far from equilibrium (Zhang et al. 2019). Catecholaminergic Neuron Electron Transport (CNET) is a hypothesised neural signalling mechanism in

catecholaminergic neurons that would use quantum mechanical electron transport. Electron tunnelling occurs in ferritin, an iron storage protein that is prevalent in those neurons. The hypothesised function of this mechanism is to assist in action selection. The mechanism itself would be capable of integrating millions of cognitive and sensory neural signals using a physical mechanism associated with strong electron-electron interactions (Rourke 2019, 2020). Fisher (2015) has also speculated that phosphorus and in particular $\text{Ca}_9(\text{PO}_4)_6$ calcium phosphate Posner's clusters might play an integral role in neural processing using quantum coherence. Estimates of coherence time vary from 105 seconds (ibid) down to 60 sec (Player & Hore 2018), but may be inconsistent with evidence from Ca^{++} dynamics not correlating with consciousness (Chen et al. 2020). We have also seen specific quantum theories of consciousness such as those of Hameroff & Penrose (2014) and Freeman and Vitiello's (2016) dissipative quantum model of brain dynamics, based on attractor dynamics and the interaction of quantum fields with water and the cytosol.

Symbiotic Existential Cosmology's approach focuses on edge of chaos dynamics as a transition to quantum sensitivity, through "excitons" distinguished from one another by tuneable wave phase coherence between continuous field voltages and neuronal action potentials, complemented by neuronal thresholds and ion channel activations as a process driven by self-organised criticality, leading to quantum sensitivity. None of these need to operate in an atmosphere of complete isolation from quantum decoherence in the "warm wet brain". They derive their basis from corresponding excitations in single celled eucaryotes, so the key step is the sensitivity of edge of chaos excitation in the single cell to quantum level changes e.g. in the ion channel, associated with sensing external quantum phenomena, from light (photons), sound and vibration (phonons), orbital interactions (olfaction) and electromagnetic disturbances.

The emergence of organismic consciousness is an evolutionary process. The brain inherited the dynamics to make our form of subjective consciousness possible long before multi-celled organisms evolved. LECA, the founding single-celled eucaryote already possessed the G-protein linked receptors found in the brain, and going even deeper -- LUCA the last common ancestor of all life, possessed a chemiosmotic excitable membrane, enabling chaotic sensitivity in the butterfly effect during bursting and beating. In the context of animal brains, these in turn, lead to phase-front processing, which forms a representation of the same dynamics involved in quantum measurement, bringing quantum entanglement into the dynamics, driven by self-organised criticality at tipping points, running from individual ion channels to whole brain dynamics, in a coherent system reaching a complexity unique in the universe.

Fig 108b: Diverse properties of superfluidity and quasi-particles in liquid helium. (a) Helium becomes liquid at 3-4 K and at much lower temperatures enable the coherent waves of superfluidity due to Bose-Einstein condensation. Superfluid phases in ^4He (2.17 K) and ^3He (1mK), once Cooper-pairs have been formed. (b) The quasi-particle experiment showing both reflected "holes" and the shadow of transmitted particles on permitted orbits (Noble et al. 2022, Eltsov 2022). (c) Quantum turbulence in rotated superfluid He consists of lattice of quantised vortices linked in vortical sheets (centre), turning with the cylinder walls (Lounasmaa & Thuneberg 1999). (d) X-rays reveal tornado-like vortices swirling in a droplet of ^4He (Cho 2015) (e) Mini-bang experiment modelling the origin of the universe in superfluid ^3He (Ruutu et al. 1996). (f) High-mass solitons generated in superfluid ^3He (Yefsah et al. 2013).

To gain a view of the potential for emergent quantum phenomena, even in apparently simple monoatomic environments, we now turn to liquid helium 3 as an oracle for the possibilities that arise in an ultra-cold environment where there are a few interfering thermodynamic interactions. ^3He has a fermionic nucleus of two protons and a neutron, and two orbital electrons, thus becomes a fermionic superfluid, that displays a variety of unstable quantum phenomena illustrated in fig 108b, including quasi-particle states, quantum turbulence, high mass solitons and cosmic string like defects. Superfluid ^3He consists of Cooper-pairs of atoms entangled in the same wave function, just as are the electrons in solid-state superconductivity, with residual unpaired complexes of atoms forming quasiparticles. This, unlike ^4He which becomes a bosonic superfluid, generating Bose-Einstein condensates, results in a situation akin to spin glasses (Oppermann & Rosenow 1996) possessing devil's staircase fractality (Çağlar & Berker 2017), in which some quasi-particle states in the medium can be forbidden to enter, if they come too close to an

obstructing superfluid tangle resulting in reflection of a quasi-particle “hole”. This phenomenon was clearly demonstrated by immersing a micro-experiment in which a source of quasi-particles generated by disturbing the medium can be either reflected off a superfluid tangle caused by a wire loop if they pass too close, otherwise passing on to the photographic plate, showing the shadow of the particles that didn't become deflected (Noble et al. 2022, Eltsov 2022).

We now transfer our focus to the biological realm of ambient thermodynamic temperatures around 25°C and the unique properties of liquid water, in relation to biological and neurodynamic processes. It is clear that these temperatures do not support the relative entropic isolation of ultra cold-state physics, but may nevertheless invoke unique quantum properties of their own. It should be noted that the fact that the most utilised high temperature superconductor $\text{Bi}_2\text{Sr}_2\text{Ca}_2\text{Cu}_3\text{O}_{10}$ (BSCCO), becomes superconducting at 110°K, well above the 77°K of liquid nitrogen and far above the 4.15°K for mercury, and that significantly higher temperatures have been claimed, demonstrates that entangled pairs can remain robust at much higher temperatures than absolute zero, showing that nascent possibilities may also exist for quantum processes in neurodynamics at biological temperatures.

Differential electronegativity in the first row elements CNO induces a symmetry-breaking between the non-polar C-H bond and the increasingly polar N-H and O-H (fig 108c(j)). This results in phase bifurcation, dividing the environmental medium into polar (aqueous) and non-polar (oily) phases in association with low-entropy water bonding structures induced around non-polar molecules. This is directly responsible for the development a variety of structures, from the membrane in the context of lipid molecules, to globular protein enzymes and nucleic acid base-stacking.

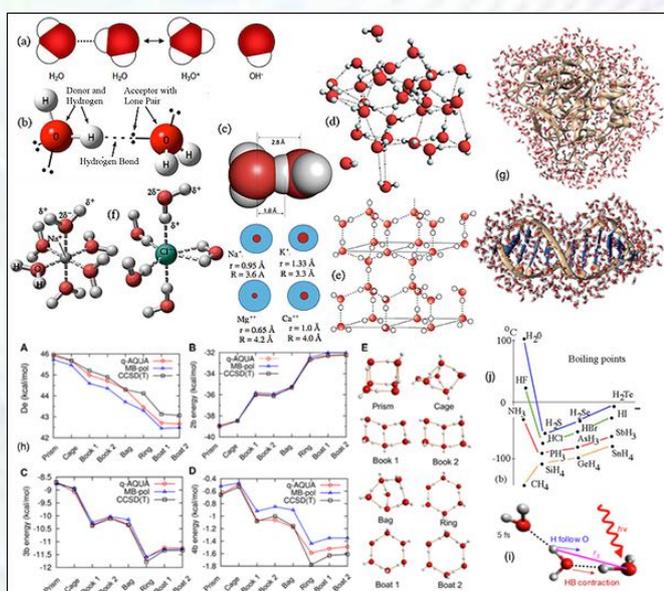

Fig 108c: Optimality of H_2O demonstrated in its varieties of interaction: (a) Dissociation into acidic and basic ions. (b) Hydrogen bonding into the oxygen lone pair. (c) Geometry of the H-bond, (d) Water's high boiling point is a function of H-bonding in which 85% of molecules at room temperature are caught in a bonding lattice. (e) The H-bonded crystal structure of ice, which is both less dense and more ordered than liquid water, as reflected in liquid water extreme specific heat (right). (f) Polar bonding of water molecules with positive and negative ions results in larger hydrated ionic radii, with naked and hydrated ionic radii shown centre. (g) Water structures surrounding the proteins, nucleic acids and phospholipids is pivotal in their biological structures, involving an interplay between polar properties of water and non-polar moieties of amino acids and nucleotide bases to form protein micelles, nucleic acid helices and the membrane structures of the living cell. (h) Many-body representation up to the four-body interaction, benchmarked for the isomers of the water hexamer of the Prism, Book, and Cage isomers (Yu et al. 2022). (i) Many anomalous properties of liquid water originate from

its well-connected hydrogen bond network, including unusually efficient vibrational energy redistribution and relaxation. Shown is a transient hydrogen bond contraction of roughly 0.04 \AA , followed by a thermalisation (Yang et al. 2020). (j) Water's unique bonding structure is also reflected in its high boiling point.

Water is one of the most important, yet least understood, liquids in nature (Yang et al. 2021). It has the highest heat capacity of all liquids, with a specific heat capacity of $4.186 \text{ Kj/g}^\circ\text{C}$ at 20°C , with ice at -1°C , 2.093 compared with kerosene 2.01 , copper 0.385 , mercury 0.140 and proteins (lysozyme 1.483). This reflects the very large number of H_2O quantum modes that can become thermally excited. Liquid water consists of a dynamic weak bonding structure, in which around 82% of the molecules at any time are bonded in locally solid configurations (Yu et al. 2022). It also contains holes and multiple liquid phases (Huang et al. 2009, Nilsson & Pettersson 2015).

Critical in this process are the optimal properties of H_2O among all molecules, as a polar H-bonding and ionising medium, making possible in turn polarity interactions, aqueous acid-base bifurcation, ionic solubility and hydrogen bonding. The optimal nature of water as a hydride is illustrated in boiling points (fig 108c(j)). Water provides several other secondary bifurcations besides polarity. The dissociation $2\text{H}_2\text{O} \leftrightarrow \text{H}_3\text{O}^+ + \text{OH}^-$ lays the foundation for the acid-base bifurcation, while ionic solubility generates anion-cation. Many key properties of proteins and nucleic acids, are

derived from water bonding structures, in which a counterpoint of H-bonding and phase bifurcation effects occur, determining the form of the alpha helix and nucleotide base pairing.

Hydrophilic-non-polar bifurcation is central to the tertiary structures of globular proteins as 'micelles' and helices and hairpins of RNAs and DNA. The solubility, or otherwise, of a variety of molecules and ions is derived from the energies and entropies of their induced water-bonding structures. Polymerisation of nucleotides, amino-acids and sugars all involve dehydration elimination of H₂O, giving water a central role in polymer formation. It has also been suggested water contains quantum-coherent domains, in association with boundaries such as macromolecules and membranes.

Complementing this is the fact that membrane excitability and neurodynamics involves movement of ions and ion transport, both generating and responding to electromagnetic fields. The dominant isotopes of H⁺, Na⁺, K⁺ and Cl⁻ are all fermionic ions, since they have even numbers of neutrons and orbital electrons (once one electron escapes or is caught to form the ion) and an odd number of protons, enabling both bosonic excitations and fermionic effects.

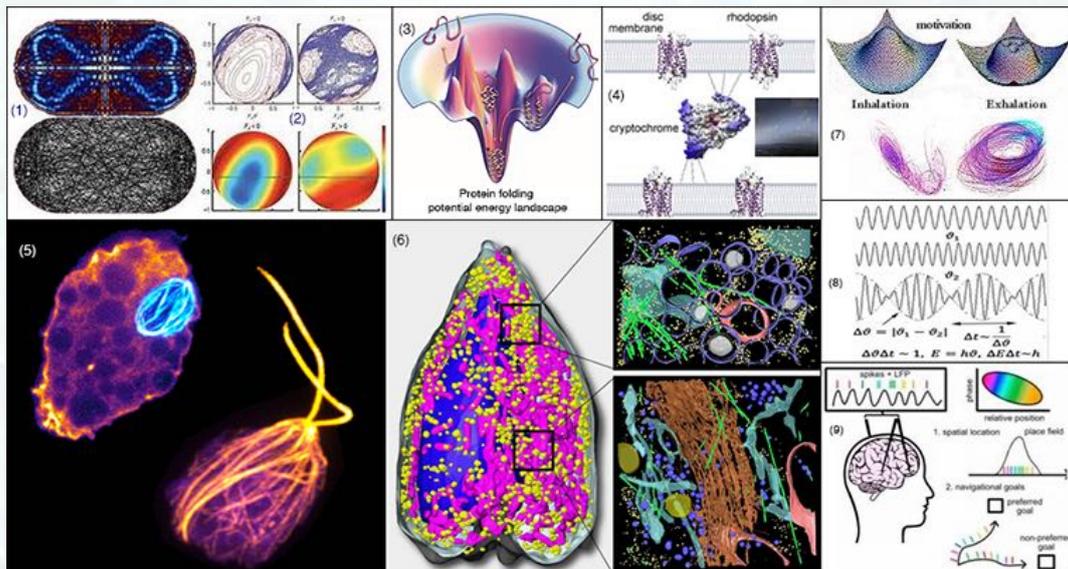

Fig 108d: (1) Quantum suppression of chaos in wave function scarring by a classical repelling orbit. (2) Quantum kicked top has a chaotic regime resulting in entanglement between orbital activation and nuclear spin. (3) Proteins have a funnel-shaped energy landscape with many high-energy, unfolded structures and only a few low-energy, folded structures. Folding occurs via parallel microscopic trajectories via quantum tunnelling. (4) Bird magnetic navigation is mediated by quantum mechanical, long-lived spin coherences in realistic models of cryptochrome, providing the necessary precision (Hiscock et al. 2016). (5) The close-to-founding eucaryote excavate *Naegleria gruberi*, which diverged from metazoa over a billion years ago, has both amoeboid and flagellated modes, and already contains actin and microtubule cytoskeletons, mitotic and meiotic machinery, suggesting cryptic sex, several transcription factors and a rich repertoire of signalling molecules, including G-protein coupled receptors, histidine kinases and second messengers including cAMP – many features essential for neuronal activity. Mitotic microtubules in blue and flagellar in yellow (Velle et al. 2022). (6) A 3D volumetric view of a pancreatic beta cell obtained using soft x-ray tomography, with the distribution of insulin granules (yellow), mitochondria (pink) and the nucleus (blue) highlighted. The boxed regions point to structural details of these regions obtained using cryo-electron tomography illustrating the fractal complexity of eucaryote cell organelles (White et al. 2020). (7) Transitions in an out of chaos in brain dynamics. (8, 9) Phase coupling between action potentials and tissue continuous potential waves realised in the EEG have homology to quantum measurement through wave beats.

If we now turn to tissues such as the cerebral cortex, [fig 51](#) shows that biological tissues are the most complex form of matter known in the universe, with diverse electrochemical and biochemical properties and hand-shaking interaction on all fractal scales, from the molecular level, through molecular complexes such as proteins, nucleic acids and ribosome, to cell organelles from the ribosome to the membrane, endoplasmic reticulum and nucleus to organs and organisms. These structures are complemented in nervous systems by patterns and pathways of electromagnetic excitation from individual action potential to tissue spanning waveforms in electrical potential in a state of mutual interaction. Pivotal to these are phase tuning between action potentials and tissue potential wave phase noted in [fig 78\(4\)](#), and transitions in and out of chaos in edge-of-chaos dynamics, noted in [fig 78\(1\)](#) and [fig 35\(right\)](#).

Phase tuning represents a potential form of quantum measurement of the brain's own excitations noted in [fig 71\(c\)](#), where the uncertainties of time and energy are related through frequency of wave beats against a reference wave.

Cerebral neurodynamics has access to this, in view of action potential emission primed by the continuous tissue potential wave phase in a way which is not available to physicists who lack a quantum reference wave. We have already seen that classical radio waves emitted by transmitter towers satisfy the conditions of quantum coherence so this relationship is potentially not just an analogy. Pivotal here is the relationship between decoherent excitations regarded as local processing and the more coherent global excitations associated with conscious brain states. This is in turn coupled to edge of chaos brain dynamics, which in self-organised critical states leads to whole excitable neurosystems becoming potentially sensitive to quantum instabilities, which due to the fractal architecture and dynamics of neurosystems, result in hand-shaking from the level of the ion channel through individual neurons to whole brain states during phase transitions from chaos to order, in decision-making, insight and perception. In this process the conscious state is linkable to the greatest complex of coherent oscillation in the brain dynamic, interacting through tuned degrees of entanglement with other partially decoherent dynamics, which may become part of the central conscious flow through phase modulation. This quantum dynamics at the edge of chaos may have anticipatory properties essential for survival, by forming a wave function surrounding the present, incorporating the immediate past and future in the emergent flow of conscious experience, avoiding the snake's strike in the immediate moment.

When we look back at quantum chaos in fig 57(1), we can see that the quantum suppression of chaos in closed systems is breached in the quantum kicked top when two quantum systems (orbital energetics and nuclear spin) have mutual coupling and become entangled. This leads to complex interactive processes in neural tissues, which have climax fractal complexity in that the systems concerned consist of overlapping coherent waveforms, that like Cooper-pairs can display resistance to simple thermally based decoherence and may rather couple to specific interactive modes defined by the precise context of a given excitation, limiting the ways decoherence can intervene and resulting in more structured forms of quantum interaction, akin to the properties of helium 3 quasi-particles, solitons and cosmic string phenomena. This combined with the fact that brain processes do not involve ID (independent identically-distributed) measurements convergent to the Born probability interpretation, due to their continually

changing contexts, means that, even at 25°C, the conventional neurodynamics in the conscious brain may well be fully quantum in nature as it stands, and not require special quantum avenues, such as Hameroff and Penrose (2014).

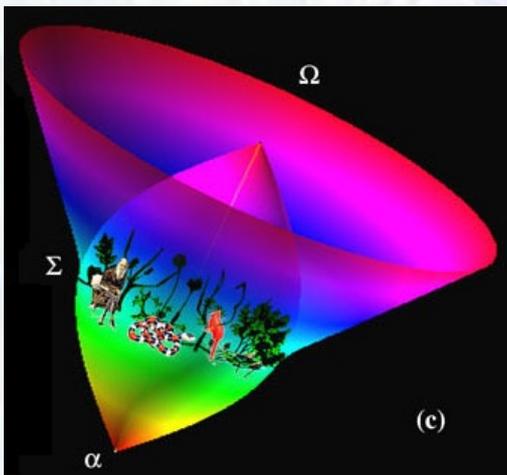

Fig 109: Paradise on the cosmic equator. According to the anthropic principle, existence of conscious observers is a boundary condition. Life can exist only once cosmic evolution has generated the elements of life and evolution has then a chance to reach an organismic climax.

The universe is thus a sentient cosmos, crowned by quantum consciousness evolving in such a way as to make possible a fully intimate connection between subjective and objective aspects of reality, in which existential "isness" and objective behaviour reach a consummation in the sentient brain in conscious perception and volitional will. Subjective consciousness can then intentionally affect the physical universe, just as we experience it to do, by collapsing the

wave function of the "multiverse" of quantum probabilities into the line, or course, of cosmic history we experience, through Schrödinger's cat paradox. This is what we experience as conscious decision-making, affecting the world around us, for better, or worse. This in turn means that, as a consummating manifestation of cosmic sentience, we have a personal and collective responsibility to fulfil this emergent quest and to preserve and unfold the diversity of life in the universe and this is what the meaning and purpose of life is all about. It is we ourselves, the universe's sentient beings, who form the consummating manifestation of the interactive catastrophe set off by symmetry-breaking in the cosmic origin and it is we who must needs protect and unfold the diversity of life and consciousness, so that the process can reach ultimate fulfilment. The buck stops with us and the fate of life within the universe becomes our personal responsibility to protect.

This cosmology, by its structural design presents a unique form of anthropic cosmology. The anthropic cosmological principle states that our location in the universe is necessarily privileged to the extent of being compatible with our existence as observers, given that we could only exist in a type of universe capable of developing and sustaining sentient life. The strong form says the universe (and hence the fundamental parameters on which it depends) must be such as to admit the creation of observers within it at some stage. Proponents of the anthropic principle argue that it

explains why this universe has the age and the fundamental physical constants necessary to accommodate conscious life, since if either had been different, we would not have been around to make observations. Anthropic reasoning is often used to deal with the notion that the universe seems to be fine tuned in terms of the relative strengths and interactions of the four forces, in such a way as to make conscious observers possible.

The phrase "anthropic principle" first appeared in Brandon Carter's (1973) contribution to a symposium honouring Copernicus's 500th birthday. He articulated the Anthropic Principle in reaction to the Copernican Principle, which states that humans do not occupy a privileged position in the Universe. "*Although our situation is not necessarily central, it is inevitably privileged to some extent.*" He defined two forms of the anthropic principle, a "weak" one which referred only to anthropic selection of privileged spacetime locations in the universe, and a more controversial "strong" form that addressed the values of the fundamental constants of physics. In effect the symbiotic cosmology "inverts" the Copernican principle by stating climax consciousness provides the ultimate privilege, by enabling the universe as a whole to become conscious.

The weak anthropic principle (WAP) states that the universe's ostensible fine tuning is the result of selection bias (specifically survivorship bias). Most often such arguments draw upon some notion of the multiverse for there to be a statistical population of universes to select from. However, a single vast universe is sufficient for most forms of the WAP that do not specifically deal with fine tuning. The strong anthropic principle (SAP), as proposed by Barrow & Tipler (1988), states that the universe is in some sense compelled to eventually have conscious and sapient life emerge within it. The Wheeler participatory anthropic principle (PAP) states that only universes with a capacity for consciousness can exist. Wheeler states: "*We are participators in bringing into being not only the near and here but the far away and long ago.*"

On Qualia

Symbiotic Existential Cosmology avoids attempting to describe subjective qualia as an analytical issue because, although it proposes primal subjectivity, it avoids any kind of formal descriptive protopsychism as any kind of structured description, as a cosmological misconception.

The physicalist viewpoint says we have trichromatic colour vision because there are three photoreceptors and the qualia form a three dimensional colour space as part of the neurodynamic analysis of photons of a single spectrum of frequencies which we don't see, but only, like a cat paradox experiment, sample as particles through rhodopsins. This means that the neurosystems have evolved to construct a 3D colour space to represent the incoming excitations. A few people have tetra-chromatic colour vision and some, particularly women who have two X-chromosomes and so can have two alleles for say the green receptor, claim to have scintillating colour vision and become artists, but they have no means to give expression to a four-dimensional colour space. Like the whisker barrels of the mouse and our dependence on orchestration of major neurotransmitter types like serotonin, GABA and glutamate to organise embryonic cortical connectivity, three colour vision space may be genetically based.

Symbiotic Existential Cosmology changes this picture, so that intentional subjectivity plays a central role in the subjective conscious volitional responses of subjective conscious intentionality changing the physical universe through our behaviour to support our survival. The brain then acts as an environmental boundary condition filter on this interactive process, so that when we hear a hiss in the dappled forest canopy, our subjective consciousness integrates all this incoming sensory "information" into the flow of experience, partly from memory, but also from the "anticipatory quantum of the conscious present". We anticipate a snake strike and maybe look to see the source but anyway jump out of the way and survive. So the Symbiotic Existential Cosmology view is subtly different from physicalism because intentionality is subjective but the palette of qualia is still driven by the filters of neurodynamic environmentally adapted processes, rather than pan proto-psychic entities in their own right, which are like a form of pseudo-physicalist mentalism.

When we take psychedelics, this all begins to make more sense because consciousness becomes synaesthetic, so sounds and colours intermingle in a single consciously perceivable mode, in which visual and auditory senses make an interplay of sonorous kaleidoscopic visions that can open out into whole dream-like visions accompanied by vast vistas and exotic scents. I remember tripping and smelling the overwhelming aroma of fried chicken, because the candle in the room was smoking, so we turn all these into something that is recognisable.

Memory is not the defining determinant of conscious experience. The stream of consciousness just uses brain-derived memories to form a contextual backdrop for actively anticipating environmental uncertainties through subjective experience and applying volition over the physical universe to make hay while the sun shines.

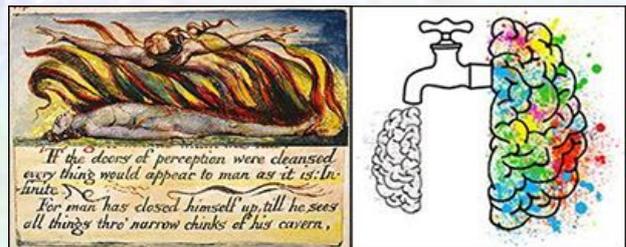

Sound is a time-evolving one dimensional frequency space taking the form of a wavelet transform that can become symphonic. Sight is a three dimensional spatial plus three dimensional colour space with other attributes like 3D edge detection and object reification thrown into the mix. All of these look and feel like the adaptive components of an internal model of reality constructed by our neurosystem. But then enters olfaction, where we have around 150 receptors and dogs have hundreds to 1000, forming the diffuse multidimensional experience we experience intuitively as delicate scents to overpowering odours. Benedictine liqueur is a good example, with about 22 different intensely olfactory molecules, each with their own receptor binding, so the neurosystems that analyse this are impossible to classify as red or blue in any structured way, yet we have a clear capacity to sense odours and scents.

Symbiotic Existential Cosmology says that subjectivity has to be optimally compliant to determined physical boundary conditions imposed by the quantum physics of the environment in terms of orbital bonding, phononic resonances in the cochlea and photon sampling in the retina, otherwise would begin to impose its own “psychic” constraints, which would inhibit biospheric adaption and organismic survival and cause potential causal conflict with brain processing. On the other hand it is able to effect brain dynamics when it is in an unstable ceritical phase transition in which outcomes are not pre-defined and may reflect root quantum uncertainty. Symbiotic Existential Cosmology’s approach to this is that physical boundary filters induce a complex adaptive subjective response, which we envision as the flow of subjective experience of reality, as a flow of environmentally adapted “hallucinations” that we all depend on, but are part of a much larger conceivable universe of which William Blake said:

“If the doors of perception were cleansed, everything would appear to man as it is infinite”.

Again when Blake says:

“We are led to believe a lie when we see with and not through the eye that was born in a night to perish in a night while the soul slept in beams of light”

He is not saying "Reality is not what you see but that which sees" as Deepak Chopra put it – that consciousness IS reality, or makes reality on its own, although it IS primary, but that it's a lie when we restrict ourselves to perceiving only the physical world, ignoring the visionary state. Seeing with is perception, seeing through is vision. The “soul” i.e consciousness can also see the light from within. The key is to look within, through our visionary “vision” not just assume consciousness is reality. We need to actually make the visionary journey across the Styx, not just stare at the ferry boat. So I see qualia as the residue of what we get when the infinity of the unconstrained “mind at large” is anchored down by the constraints of neurosystem adaption, not determined by the brain's neurosystems, but constrained by the boundary conditions of the reducing valve of physical perception. We have to deal with qualia as part of the vision quest and go right into it all, not try to analyse how it happens, but just go into the Nierika and see what the journey unfolds.

Multiple Minds and One World: Why SEC is ICAM

In the veridical way existential reality is generated, subjective experience is primary – 100% of our knowledge of the world around us, and of our visionary inner landscapes of awareness, are derived through our subjective conscious experiences of reality. The world around us is then realised as a sensory subcategory of these experiences, through the consensual overlap of our subjective perceptions of external realty, through which we gain a common experience of the physical world. We then interpret these as “physical existence” in a universe containing biological brains, which, like ourselves, appear also to be able to have private inner subjective experiences although we can’t directly perceive them. We may also, in meditative and entheogenic states, converge to an inner reality which we experience in the stream of consciousness, unbound by sensory constraints, in what appears to be a unified ‘cosmic consciousness’.

By contrast, the attempted construction of reality from the physical universe and its brains remains incomplete because there is no means of any explanation, or even any idea of what such an explanation would be like, concerning how the brains can also have private, integrated, wholistic subjective conscious experiences – the hard problem of consciousness research. Pure materialism thus completely fails to explain, let alone manifest, how or why we have an

inner conscious life at all, and worse still, completely denies our volitional ability to mentally affect the physical world around us, when we are intentional conscious agents having to have intentionality to ensure our survival in real time.

Notwithstanding the notion of a probability multiverse in some quantum interpretations, we experience only one world at large, in which matter is subdividable and decomposable, but we are a multitude of integrated wholistic subjective conscious minds, that can't see or communicate with one another's consciousness directly, but only through our vivacious volitional behaviour in the physical world, although telepathy may be an adventitious, if ephemeral, potentiality. Our minds, rather than experiencing physical reality, in and of itself, which consists of colourless, odourless quanta possessing no sensory features but only energy, wavelength position and inertia, perceive reality subjectively only through an internally generated model of reality providing the idealised 'hallucinatory' interior mental view we call "being conscious of our subjective experience", which extends beyond physicality, although filtered through neurobiological sensory processes such as three colour retinal vision, Fourier frequency representations of sound, multidimensional receptor olfaction and internal somatosensory 'feelings', of love and lust and longing, in a sentient 'world' of colour, sound and other subjective qualia which we cannot subdivide, but which flow through us continually in an unbroken whole. The key to all this is volition over the physical world around us – that we are subjective conscious beings possessing intentional will to act and survive as biological organisms in the physical universe.

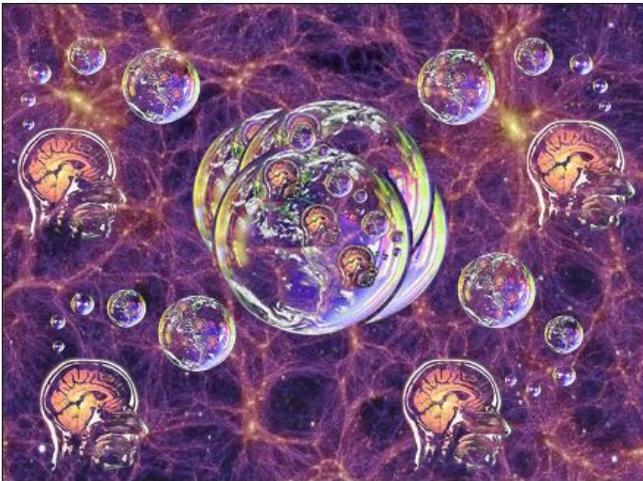

Fig 109b: Multiple subjective holistic conscious volitional minds converge to a consensus mental view (centre), of the physical world around us, involving a single divisible engulfing universe (background). In the physical view there are multiple objective brains, but each invokes a unique private conscious experience, evident only to the subject.

The relationship is not, and cannot be, a bijective duality between a single world and multiple minds, unifying the 'inner' conscious and 'outer' physical views, because there is not a simple bijective duality as a whole between the subjective and objective aspects. Strict 2-component dual aspect monism frameworks, such as Awret (2022) and Vimal (2022), cannot describe veridical reality as it is, even when they involve asymmetric dualities such as the AdS/CFT holographic

principle, or a strict bijection between individual conscious experiences and their neural physical bases. They freeze the subject-world relationship in a non-interactive bijective correspondence that doesn't adequately explain why multiple minds exist in a single universe, or how subjective conscious volition occurs veridically over physical reality, because the subjective is confined to a ghost in the machine of the brain, forced in lock-step with physical processes, making them existentially equivalent to identity theory, little different from the unconscious zombie that manifests no subjectivity at all in a pure physicalist description, despite hypothetically replicating a "brain's physical processes".

Although Awret's use of the holographic principle is a potent oracle for the complementary natures of subjective and objective, there is no evidence subjective experience is more like an abstract gravitational theory than the quantum universe we know. It is then ensnared in an eliminativist denial of volition, inconsistent with subjective empiricism and with survival of the subjectively conscious organism, in a way which cannot be directly falsified as claimed: *I am an eliminativist on free will. This position is easy to defend. I know that I have the ability to change my mind and privately so but lets not exaggerate. You seem to suggest that the indeterminism associated by the collapse provides room for consciousness to 'bias' the collapse in certain instances. The good news is its falsifiable, the bad news is that it is ridiculous.*

The claim to bias is untenable because there is no evidence subjective volition violates the Born probability interpretation yet theories, from transactional super-causality to super-determinism, could provide more subtle correlations or even causal interactions below the Born-measurable level. Awret in personal correspondence contrasts his view with Sean Carroll (2020), as allowing for a more versatile relationship, enlarging isomorphism to an asymmetric bijective duality, but at the cost of an explicit rejection of free-will:

Consciousness exists. It's real. I talk about it all the time. I asked this question to people like Sam Harris, who don't believe in free will. Have you never tried to make a difficult decision? Do you really just say, well, let the laws of physics do what they're going to do? Of course. At the level where we talk about people, we attribute choices and volition to them like we attribute conscious

experiences to them. And I'm all in favor of that. I think that they exist. They're real. They should be treated as such. That doesn't provide any evidence at all that they are not isomorphic to physical things going on in the universe.

However, the more versatile dual aspect framework of the Pauli-Jung conjecture (Atmanspacher 2012) may do so because it suggests induced, occasional, evasive mind-matter correlations, in which the physical is not completely independent of the mental, and both are not independent from the assumed reality underlying them, as exemplified by Jung's notion of synchronicity. This idea stems from the *Unus Mundus* – or “one world” of existential experience of the mediaeval philosophers that goes back to the legend of Plato's Cave. In the Pauli-Jung conjecture, the physical state is holistic before measurement, and the subjective aspect involves the unconscious emergent into consciousness, together with archetypes being open to synchronicity, or “meaningful coincidence”, being made possible by the fact that both the observer and connected phenomena ultimately stem from the same source, the *unus mundus*. Pauli in particular talks about the “autonomous activity of the soul” as “something objectively psychical that cannot and should not be explained by material causes. The room left in the versatile account allows for correlations below the level of measurable events. A hidden variable theory which determines the outcome of collapse in terms of the complex interactions of the cosmic wave function could provide just such a correlation with subjectively experienced environmental uncertainties, themselves having a critical impact on organismic survival.

Symbiotic Existential Cosmology, which likewise accepts as axiomatic primal subjectivity, in which subjective conscious volition has efficacy over the physical universe, is thus classified as ICAM – interactive complementary aspect monism because there is a single extant reality comprising the universe and all our conscious experiences, both of the physical world and of our own inner realities, which are complementary, and as Pauli has commented, like quantum complementarity, subjectivity and objectivity are mutually exclusive, although both are essential complements to sentient existence, which are not bijectively dual, but are interactively coupled, either by underlying correlations, or interactive causes, in our both possessing subjective consciousness of the world around us and executing our conscious intentional agency, in subjective conscious volition over the physical universe.

Psychedelics and the Fermi Paradox

The relationship between [psychedelics](#) and the [Fermi paradox](#), [detailed in the introduction](#), is the most controversial part of Symbiotic Existential Cosmology, so an explanation is in order. The Fermi paradox is the question: Why is there no evidence of life out there in the universe, given that from what we already know, it is a [very probable](#) occurrence? Is it because it's hiding, or because dominant cultural civilisations become unstable in evolutionary time scales and self-destruct in a [Fermi extinction](#)? Even if life is extremely unlikely in the universe as some measures suggest (Sandberg, Drexler & Ord 2018), the primary importance of protecting life on Earth is commensurately increased. Brian Cox on the BBC ahead of COP26 warned that [Earth's demise could rid galaxy of meaning](#) Brian notes on the BBC that ‘Unique events that led to civilisation mean its demise could ‘eliminate meaning in the galaxy for ever’.

Fig 110: An artist's portrait of a psychedelic experience.

The word *psychedelic* means “psyche revealing”, where *psyche* means the human mind, soul, or spirit and *dēlos* means ‘clear, manifest’. The classic 5HT_{2a} psychedelics are paradoxical serotonin receptor super-agonists that appear to induce a distinct second signalling pathway that sets off different processes from simply a surfeit of serotonin, putatively involving serotonin-glutamate receptor dimers that metabotropically modify glutamate excitation across the cortex. By contrast, both SSRI anti-depressants and entactogens affect the serotonin transporter to increase serotonin levels at the receptor, but the entactogen MDMA is not a psychedelic. It gives a strong serotonergic high amid touchy feely ‘love drug’ sensations, possibly because of secondary oxytocin effects, but not a psychedelic ‘trip’.

[Psychedelic](#) species and substances set off a flood of incoming sensory stimulation, combined with a tendency for the default mode network to go silent, resulting in the experience of ego loss, and in combination with meditative repose, can become full blown [quantum change](#) experiences, in which religious people may experience God or “divinity”

alternatively described as “ultimate reality” by the non-religious. Hence the name *enthogen* is applied to their ritual use in spiritual and shamanic contexts. Of course, in negative contexts, this can become Heaven and Hell as Aldous Huxley pointed out, so good conducive contexts are critical. But the fact that psychedelics are being used to treat terminal illness and severe depression successfully shows that, even in dire contexts, they can be very beneficial.

Psychedelics effectively induce a situation where subjective consciousness begins to derive an internal model of the reality of its own internal dynamics, invoking kaleidoscopic geometric figures and synesthesia – resonant mixed sense-mode experiences, in which accentuated daydreaming evolves into veridical visions – actual perception of observational realities ‘out there’, and finally the existential experience of union with the ‘other’ – the signature of Brahman-atman and peak accounts of near death experiences.

So while meditation alone can result in states of peaceful mindfulness and compassion and in some people mystical experience, brain studies of meditation reveal a more controlled state of oscillatory synchrony amid a sparser spiritual or mystical experience. This explains why moksha is so rare and why the Eastern tradition resorts to reincarnation to seek enlightenment in a future life cycle, although some people with conducive genetic biochemistry enter these states more often naturally and can become mystic visionaries, leading both to new religions and cultic misadventures.

Psychedelics can reveal, in far greater first-person depth and illumination, the dimensions of the visionary experience shared by religious mysticism and meditative repose, and do it in a way which is characteristic of those aspects of near death experience that take us to the very edge of existence. The psychedelic experience gained from ingesting a psychoactive species is not a false vision, or inferior to a pure spiritual experience and is modulated as part of the attentive experience of the subjectively conscious observer, who remains able to distinguish reality from fiction. Bringing all these together, we have a research recipe for the subjective equivalent of the LHC in cosmological physics. We can tie this phenomenon to edge-of-chaos modulations disrupting the perceptual filters in our neurodynamics that our evolution as a species has selected for, to confine the observed plethora of internal and external information to a vastly reduced core subset, tuned down for organismic survival.

The key markers of human selection have been Machiavellian social intelligence on the one hand and the “mating mind” (Miller 2000) on the other, where astute female reproductive choice has led to an XY-chromosomal peacock’s tail runaway of super-intelligence (Fielder & King 2017) amid the softer, kinder aspects of perpetual human sexual receptivity amid human sensual love and longing, but nevertheless, with the loss of innocence of our original virtues of verifiable trust in good character over time during our gatherer-hunter phase in small bands of people, human evolution since has clearly been towards an increasingly urban patriarchal culture of human dominance over other humans, the female sex and the diversity of nature, enshrined in the growth of the egotistical mind as an overblown survival tool turned into the pursuit of dominance and power.

Human cultures have reacted to this dilemma by altruistic punishment, asserting prescriptive highly incorrect moral cosmologies, while extolling the ideals of virtuosity and compassion. In recent form, this has led to utopian notions of humanity, combined with artificial intelligence, and technology, becoming dominant forces in the mechanistic universe, violating our symbiotic relationship with nature and woman alike, leading to the mass extinction of biodiversity and our own attrition or extinction.

In the pursuit of longevity, amid human cloning and genetic modification, those seeking human immortality are trying to turn themselves back into parthenogenetic organisms whose life span is indeterminate, but this is ultimate selfishness. No parthenogenetic species can survive long term without sexual recombination and the biosphere to support it so this is a cul de sac and evolutionary suicide, as is any form of species dominance that violates the fundamental principle of biospheric symbiosis of all species within it.

So the question remains: Why are there psychedelics and do they have a meaningful role in the evolutionary process? If we go back to biogenesis itself, we have a partially solved problem of far-from equilibrium fractal molecular chemistry breaking through to the RNA era. Nevertheless, given the organic gas clouds of Orion, the lost city vents littering the primordial olivine ocean floor and other catalytic processes, all except the hard end of intelligent designers accept that this is a natural process. Likewise for the eucaryote emergence, which after all is a symbiosis of the two complementary foundational life forms, archaea and bacteria. We also have the tendency of adventitious mutation within the biosphere’s diversity to produce a plethora of organic molecules, so it’s hardly surprising if some of these are psychedelic, in our case on Earth the classic psychedelics – psilocin, DMT, and mescaline.

But there is another side to this story. The human brain is actually an intimately coupled society of some 10^{10} neurons communicating and modulating their activity through the same core types of neurotransmitter amoeboid-flagellates evolved as single-celled organisms for social signalling. We think of the brain as predominantly electrodynamic, but it is a profusely sappy biochemical organ in which electrodynamic excitation is punctuated and mediated by biochemical synaptic transmission. The metabotropic receptors modulate key dynamical modes from direct excitation and inhibition (glutamate, GABA and acetyl-choline) through waking activity vigilance, mood and drive (nor-epinephrine, serotonin and dopamine) to the stages of light and dreaming sleep involving several of these.

An evolutionary key here is that these neurotransmitters are also formative developmental morphogens. Serotonin for example retains a similar role in human brain development to that as the fruiting tip organiser in *Dictyostellium*, extending from maternal serotonin inducing the neural crest all the way through to the ascending 5HT1a pathways fanning out across the cortex (later modulating wake and sleep modes) acting in development as primers for the cells which organise the layered structure of the cortex. This means that modulating neurotransmission can alter primal evolutionary survival modes evolved through the deep developmental roles conserved since our single celled ancestors by the same neurotransmitters

So the hypothesis connecting psychedelics and the Fermi paradox is that evolution climaxing to the emergence of a dominant cultural species like Homo involves a narrowing of the experiential filters to promote species dominance which then becomes a critical flaw, in species dominance and exploitation precipitating a mass extinction of the diversity of life through habitat destruction and the depletion of resources, in a non-renewable energy consumption and population burst, causing severe climatic change and disrupting planetary habitats on a global scale. This is the Fermi apocalypse catastrophe we are witnessing.

The natural antidote to the destructive Fermi apocalypse is that the kind of climax driven by a dominant cultural species also occurs at peak biodiversity, after a long period of fecund prosperity, in our case since the Tertiary-Cretaceous extinction, and this results in a 'salting' of the biosphere with biomolecules which modulate the neuronal activity of a dominant species in such a way as to carry its conscious neurodynamics closer to the climax edge of experiential chaos than its own evolutionary species selection became adapted for. This is then a way the fullness of evolutionary climax comes to reestablish the symbiotic biosphere, because changing the consciousness of the dominant species liberates it from its evolutionary constraints. Because any dominant cultural species seeks to understand what the hell it is doing in the universe, this becomes a catalyst for its own self-discovery.

This is not a magic process of divine psychedelic intervention, but might come to explain the other good half of the Fermi paradox. A dominant species which discovers its psychedelic species and learns to use their paradoxically disturbing properties, then begins to protect and even cherish its biosphere as sacred and integral to the evolving cosmic "design", for the lack of a better word, and thus, instead of proudly announcing its dominant existence to all comers, or failing one of the many triple witching hours of its own cultural, political, economic and environmental instabilities, instead settles into discovering the abyss of its own conscious experience as a convergent symbiosis with the conscious universe as a whole.

This is what I term cosmological symbiosis, thereby settling into a much more cerebral perennially immortal existence, complemented by the use of renewable technology and adroit strategies to protect the biosphere from astronomical crises, such as massive impacts and nearby supernovae, by careful use of its solar system habitats to avoid putting all its eggs in one basket and to remain concealed in the universe at large, to avoid predatory exploitation from without. This is the Fermi paradise on the cosmic equator in space-time.

In this sense, the notion of union with the cosmic mind is also not a magical process, although it is magical to experience and spiritual to the core. It is simply allowing our own subjective consciousness to reach edge of chaos climax while running egoless in neutral, thus enabling a rapprochement between the organismic brain and the foundational dynamics that invoke the mind at large, as an archetypal dynamical system, expressing in the fullest and most resonant way, the consciousness of the universe, expressed through its climax biota. The differences from traditional spiritual realisation can also be seen in its reverence of nature as sacred consistent with the Weltanschauung of Immortality, rather than the mind-sky view of cosmic transcendence over nature, all too anthropomorphically seeking only human transfiguration in enlightenment in the Eastern traditions, where nature is just degenerate sentient beings and the biological and genetic basis as nature's embodied sacredness is set aside. So the healing is this.

Evolution of the biosphere has a safety valve for the human egoistical destruction of Gaia. It's just a product of the sheer adventitious fecundity of evolution, not a magical phenomenon. But it has the capacity to bridge the gap between humanity as unnatural evil and humanity as "we are nature". This is proven by the fact that the very substances suppressed by Western culture in the 1960s, in an echo of the Inquisition and witch hunts, have now become a cutting edge treatment for severe depression and the existential nightmare of terminal illness.

Now here is the deep paradox. The Western religious tradition, sourcing from Yeshua, is a sacramental tradition. The synoptic gospels claim Jesus instituted the carnivorous sacrificial sacrament of his own flesh and blood in the last supper. *"And he took the cup, and when he had given thanks, he gave it to them: and they all drank of it. And he said unto them, This is my blood of the new testament, which is shed for many."* But where did this historical disjunct, so un-Hebrew arise? We have to look further to his all too Dionysian miraculous behaviour supported by the women of Galilee "out of their very substance". The entire mission is an apocalyptic presentation of Dionysian tragic theatre, inherited from the sweeping victory of Alexander the Great, leaving in his wake a Greek culture that extended across Syria and Jordan to the Nabatean cultural climax in Yeshua's time, where Dhushara became his manifestation. Dionysus is the god of wine and altered states supported by the maenads whose pupils were dilated with belladonna.

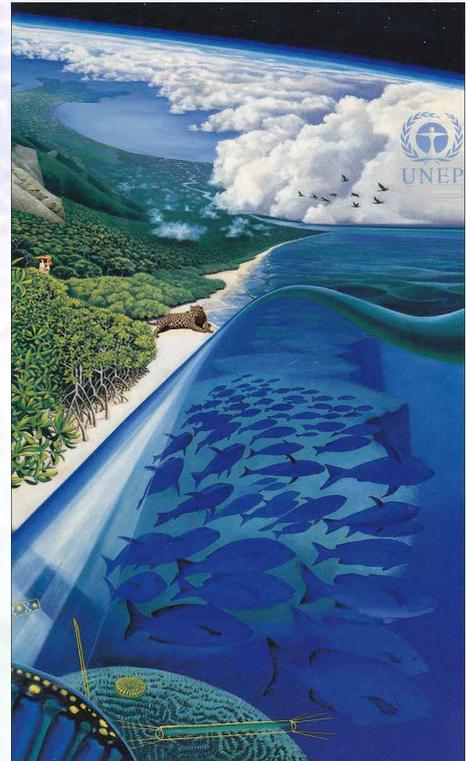

I didn't invent psilocybe mushrooms, the evolutionary biosphere did. I concealed my use of them for 50 years and went to Jerusalem in the millennium to pronounce the epoch of the Tree of Life because they "told me so" a decade and a half before, but now they have been researched scientifically and found to have genuine transformative value.

We all have to accept the fact that the founding religion of Western culture is sacramental and it is no coincidence that I now stand here as the spokesperson for the Tree of Life holding the sacraments of the biosphere. That is the healing because it is the scientific way for egotistical human nature to become liberated in time to save life as a whole. This doesn't mean everyone should be taking psychedelics. It just means that they are part of the solution and when they are accepted as such, a new horizon beckons. Enough of a good part, given their newly recognised status to make a real transformation of human culture for the better.

My experience of Brahman in the moksha epiphany that triggered this cosmology was not a false vision. I stand by the Upanishads as an empirical account! I stand likewise by the Gospel of Thomas as a personal statement of Yeshua's visionary nature. I stand also by Maria Sabina and Gordon Wasson.

Fig 110b: A picture of symbiotic climax in the biosphere. The cover of UNEP's Global Biodiversity Assessment 1995, for which I was a reviewer, with mushroom and jaguar added to represent land animals and fungi.

My June 2021 experience was all the more genuine because I am an extremely level-headed scientist, fully aware that I have intentionally taken my conscious neurodynamics to the edge of chaos to liberate it from the filters of my own evolutionary confinement. I can then return to the fold and set to work to discover what kind of universe can actually make this all possible in scientific terms. Instead of a raft of religious edicts and doctrine, and a lifeless mechanistic physical account. Humanity gets the living cosmology of quantum reality and conscious existence that is empirically verifiable and detailed across a wide spectrum of disciplines.

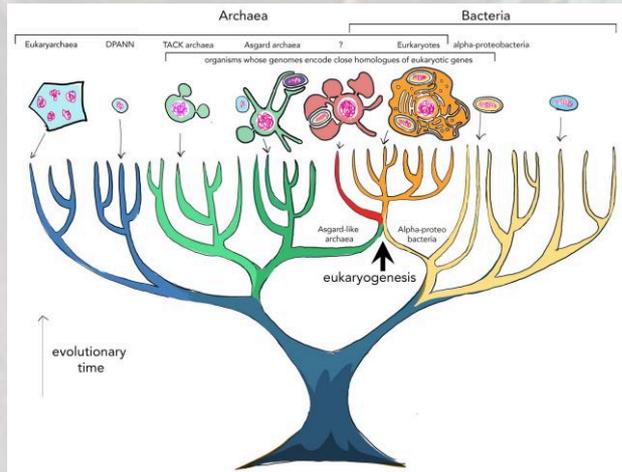

The Evolutionary Landscape of Symbiotic Existential Cosmology

Symbiotic Existential Cosmology is fundamentally a **profoundly evolutionary cosmology**, in which the integrative nature of both genotype and phenotype, modified only by small mutational changes, ensures the biosphere as a whole retains unfolding climax stability over evolutionary and cosmological time scales. In a sense it is **an account of a voyage**, just like Darwin’s voyage on the Beagle, leading to “The Origin of the Species”, except that this written work is an account of a vision quest into all the subjective, physical, cultural and religious aspects of the existential reality of conscious existence in the natural universe. It is an innovative evolutionary quantum cosmology in which:

- (1) **Mutations** are viewed as **quantum uncertain transformations** following a non IID sequence which fails to converge to the probability interpretation, modulated by natural and sexual selection, rather than simple randomness (Santiago-Alarcon et al. 2020, Monroe et al. 2022).
- (2) **Major evolutionary transitions**, including **abiogenesis**, the **great oxygenation**, the **eucaryote endo-symbiosis** the **Cambrian radiation** and our **cultural emergence**.

Fig 111: The Tree of Life merger that made us in the eucaryote endo-symbiosis (Baum & Baum 2020).

- (3) **Natural and sexual selection** of metazoa is mediated by an animal’s **subjective conscious volition over the natural world**. Sexual selection and its mutual runaway effects in a Red Queen race (Ridley 1993) have also had profound creative influences on evolution pivotal to human intelligence and cultural emergence.
- (4) **Modular regulatory evolution**. See figs 127, 130 & 100, show that transposable elements and endogenous retroviruses which occupy nearly half the human genome, are both capable of mutational insertion of new elements as well as having been utilised in essential symbiotic roles, complemented by supergenes (Arnold 2022).
- (5) **The organismic development process** is also coupled to genetic evolution (evo-devo). Fig 120 shows this in homeotic gene evolution underlying segmental development across the metazoa, fig 112 shows it in non-coding DNA and fig 122 also shows the approach in the evolution of the human brain as a social neuronal organism.
- (6) **Biospheric symbiosis**: Natural and sexual selection results in the fittest biospheric symbionts, not the most competitive dominant species, exemplified by the eucaryote endo-symbiosis and multiple predator-prey and parasite-host relationships rising to climax diversity.
- (7) **The mutual coupling of genetic evolution to cultural evolution**, with the emergence of culture and language, has resulted in a multilevel selection paradigm in which cultural elements reinforced across generations, also influence genotype and organismic phenotype, and vice versa.
- (8) **Cosmological symbiosis** in which **gene-culture-biosphere co-evolution** ensures biospheric and human survival.

Gregory Bateson (1972) viewed all three systems of the individual, society and ecosystem as together a part of one supreme cybernetic system that controls everything instead of just interacting systems. This supreme cybernetic system is beyond the self of the individual and could be equated to what many people refer to as God, though Bateson referred to it as Mind.

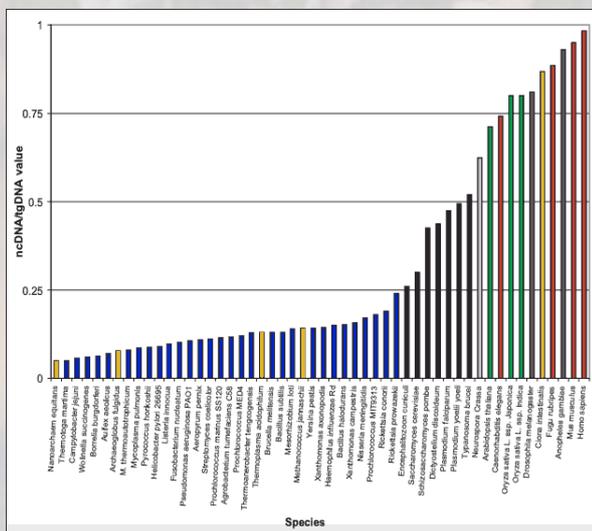

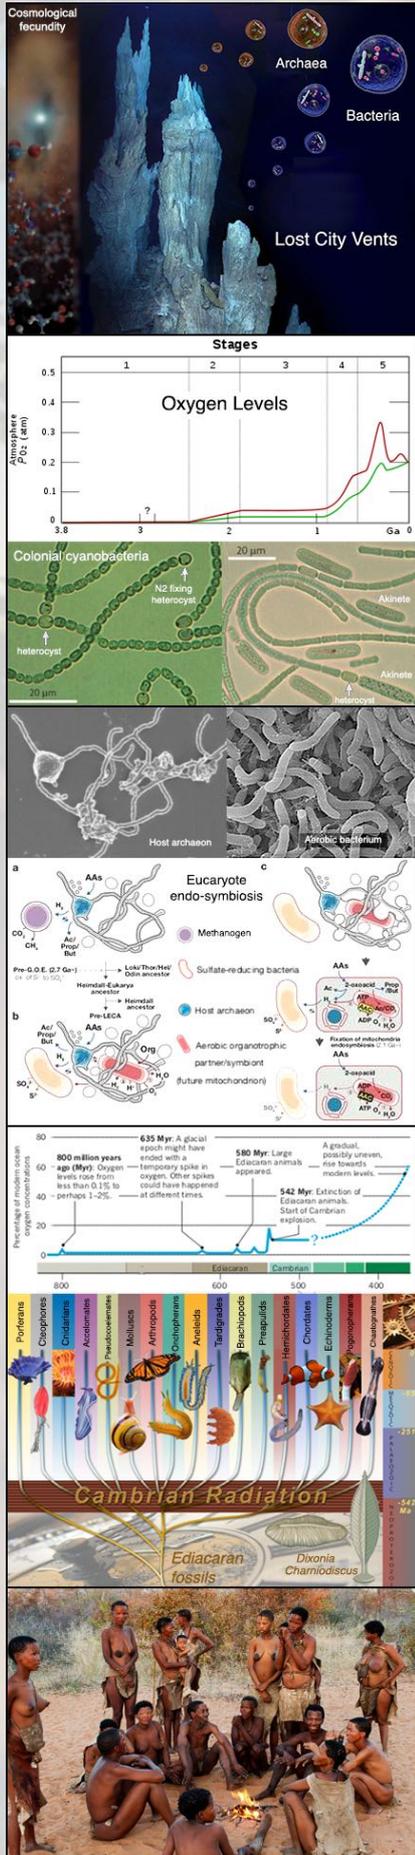

Fig 112: Increase in the ratio of noncoding DNA to total genomic DNA correlates with increasing biological complexity from 0.05 in *Nanoarchaeum* to 0.983 in *Homo*. Archaea in yellow, bacteria in blue, unicellular eukaryotes in black, the fungus *Neurospora crassa* in light grey, plants in green, non-chordate invertebrates in red, the urochordate *Ciona intestinalis* in yellow, and vertebrates in dark grey. It is key to understanding how higher organisms, through to ourselves, were able to evolve, because single base pair mutations of non-coding DNA are less disruptive, as they don’t have to be translated and make only a differential change to RNA and promoter binding. Complementing this, natural and particularly sexual selection is both phenotypic and conscious (Taft & Mattick 2003). This means that humans have only 2.82 times the coding genome of the amoeboid slime mould *Dictyostellium discoideum* and 2.7 times as many genes, with only 2.0 and 1.57 as many compared with the simple roundworm *Caenorhabditis elegans*. Evolution has thus become a symphony on largely the same genes, as is also made clear in the great gene diversification 3 bya ago in fig 128 .

Five Major Evolutionary Transitions

The Origin of Life – Abiogenesis to LUCA (4.4 – 3.5 Bya)

Fractal biocosmology has already been extensively explored in the cosmology section, in which the evolving universe is highly fecund for biogenesis and leads through a transitional phase of establishing the genetic code and protein translation eventually to arrive at LUCA, our last universal common ancestor, which may have been a progenote, a loosely interacting RNA-based system before the independent emergence of archaea and bacteria as free living cells, fig 99, whose cell membrane components are distinct, with complementary strategies, consistent with the overall time interval above (Grimm & Marchi 2018, Schopf et al. 2018).

The Great Oxygenation Event (GOE) (2.4 Bya)

Although the first life forms depended on a variety of energy sources, including chemical gradients, all ongoing life depends ultimately on photosynthesis. The first evidence for the existence of molecular O₂ in the atmosphere and ocean dates to 3.1-3.5 Bya, consistent with cyanobacterial emergence (Cardona et al. 2018, Jabłońska & Tawfik 2021). The origin of the Great Oxygenation circa 2.45–2.32 Bya coincides with the evolution of colonial multicellular forms of cyanobacteria (Schirrmeister et al. 2011, 2013), in which specialised heterocysts (Flores & Herrero 2009, Kumar et al. 2010) enable fixation of nitrogen at higher oxygen levels, by disabling photosystem II (Cardona et al. 2018). The earliest known akinetes – dormant multicellular cyanobacterial cells (Sukenik et al. 2019), are preserved in 2.1 Bya chert from West Africa (Tomitani et al. 2006). The final rise in O₂ at 0.8 Bya corresponds to emergence of eucaryote algae and higher plants. Red algae have been dated as far back as 1.6 Bya (Bengtson et al. 2017).

The Eucaryote Endo-Symbiosis – LECA (2.1 – 1.5 Bya)

The eucaryote endo-symbiosis (Imachi et al. 2019) has already been discussed extensively in the cosmology section and forms the greatest evolutionary transition since the origin of life, giving rise to all complex life forms. What is pivotal about this is that it is an evolutionary biological co-adaption to one or more symbiotic interactions between complementary species, but does closely follow the O₂ increase set off by the great oxidation as a precursor, consistent with the overall time interval above (French et al. 2015, El Albani et al. 2010, Bengtson et al. 2017). The sheer scope of this transformation can be seen from fig 112 where there is a jump of 25x in total genome, 17x in protein coding genome and 8x in coding genes from the bacterium *Rickettsia conorii* to the amoeboid slime mould *Dictyostellium discoideum*, contrasting with the small coding genome expansion since of ~2.8x.

The Cambrian Radiation (541– 521 Mya)

The Cambrian radiation corresponds to the greatest burst of animal complexity and diversity in the evolution of life. Central to this transition is a tipping point in developmental complexity governed by homeotic genes which evolved in single-celled eucaryotes (Derelle, et al. 2007), but reached a critical transition in the Cambrian radiation, giving rise to all the extant higher animal phyla through developmental evolution. By comparison, the previous Ediacaran fossils show very limited complexity. It has been suggested (Fox 2016, Evans et al. 2022) that a transient rise and then fall in oxygen levels, probably due to emergence of new algae and plants, was associated with a mass extinction of Ediacaran fauna and the rapid rise of animals with active predatory behaviour and intelligence, spreading to the resulting vacant niches. This is consistent with a modern-style marine biosphere rapidly emerging during the Ediacaran and early Cambrian, followed by broad evolutionary stasis (Paterson et al. 2019). The rise of land plants has been dated back to 500 Mya (Morris et al. 2018).

Human Emergence and Cultural Evolution (300 – 200 Kya)

The emergence of *Homo sapiens*, and the rise of human culture and technology, beginning with tool-making and then extending to agriculture and animal husbandry has both transformed the face of the Earth, and with it brought about a new paradigm of cultural evolution, driven by spoken and written language, cultural memes and the advent of social, scientific and political discourse spanning the generations. This is now running a huge risk of causing a mass extinction of the diversity of life, precipitating a potential Fermi self-extinction – the Medea hypothesis (Ward 2009), unless our species can regain biospheric symbiosis.

The Extended Evolutionary Synthesis

This places the evolutionary view of Symbiotic Existential Cosmology as lying within the extended evolutionary synthesis (Pennisi 2008, Laland et. al. 2014, Buranyi 2022), which includes multilevel selection, transgenerational epigenetic inheritance (Felsenfeld 2014, Benetti et al. 2022, Kabacik et al. 2022), which can affect macro-evolution (Jablonka 2017), niche construction, evolvability, and evolutionary developmental biology (evo-devo) comparing the regulatory and developmental processes of different organisms to infer how developmental processes evolved (Gerhart & Kirschner 2007). The inclusion of gene-culture coevolution augments this view, to encompass cultural reproductive processes involving *memes* – a concept, social process or institution that spreads from person to person within a culture and often carries symbolic meaning that can self-replicate, mutate, and respond to selective pressures.

All species have evolved mechanisms of phenotypic plasticity that enable them to respond adaptively to their environments. Some mechanisms of phenotypic plasticity count as evolutionary processes in their own right. The human capacity for symbolic thought provides an inheritance system having the same kind of combinatorial diversity as does genetic recombination and antibody formation. (Wilson et al. 2014).

Culture is phenotypic plasticity that acquired its own intrinsic capacity to change and is now out of genetic control. We don't expect a flu virus to operate to our advantage, so why should we expect a 'mind virus' always to be in our interests? For meme advocates, not only is cultural evolution largely unconstrained by genetic pre-dispositions, but genetic evolution may itself be driven by cultural imperatives (Laland and Brown 2002 319) .

'Meme' is the name given to such units of culture and, as some memes are more likely to spread than others, there is a new kind of evolution generated at the cultural level. Somewhat disturbingly, the selection of one meme over another may be of no advantage to the individual human being; rather the meme makes use of us in order to replicate itself. Memeticists suggest that human beings may behave the way they do not because it is in their interests but because their minds have been infected by a cultural virus. Could consciousness be little more than a collection of memes? Are the dominant world religions neither true nor even beneficial, but merely those complexes of religious ideas that happen to be best at spreading? (Laland and Brown 2002 24).

Melkikh A (2014) proposes an extended evolutionary model of partially directed evolution, based on the learning automata theory, which includes a priori information about the fitness space. A potential repository of such prior information is the states of biologically important molecules. notes that many researchers have proposed and explored quantum properties in biology that could effect evolution and have proposed that molecular machines associated with reading DNA exhibit quantum properties.

| Type A evolution (undirected) | Type B evolution (partially directed) |
|---|---|
| There is no a priori information about future states | There is a priori information about future states |
| Sequence does not "see" the surrounding feature space | Sequence "sees" a neighborhood in the surrounding feature space |
| Robustness is not necessary and is only an unnecessary cost | Robustness is beneficial because it is known which pieces of sequence should be preserved |
| Evolvability is not profitable because it can worsen the genotype | Evolvability can be profitable if it is known how the environment will change |

Josephson & Pallikari-Viras (1991) note the differences between classical and statistical quantum science where results are classically or statistically determined and adaptive living systems where organisms may be able to exploit quantum nonlocality and entanglement through adaptive, rather than universal knowledge:

The first, the method of science, is to retain conformity with the demands of reproducibility and universality by the device of replacing the no longer possible strict determinism by statistical determinism. The outcome of this approach is quantum mechanics. The second, a method that is in general terms favoured by life, involves renouncing the demand for universal knowledge in favour of more specialised and purposeful adaptations to the more limited class of situations that the organism or organisms concerned is liable naturally to encounter in the course of its life.

Laland and Brown note Dawkins' (1976) original discovery of the term:

He coined the terms 'replicator' and 'vehicle' to distinguish between the 'immortal' genes, which are replicated each generation, and the transient, vehicular organisms that house them. The gene is the archetypal replicator, but Dawkins proposed that a new, frequently insidious kind of replicator has recently emerged on this planet, a mind virus that infects us with catchy concepts and fashionable ideas. "We need a name for the new replicator, a noun that conveys the idea of a unit of cultural transmission, or a unit of imitation. 'Mimeme' comes from a suitable Greek root, but I want a monosyllable that sounds a bit like 'gene'. I hope my classicist friends will forgive me if I abbreviate mimeme to meme."

The word **evolution** itself is plagued by a spectrum of meanings. Oxford languages defines it's scientific meaning as "the process by which different kinds of living organism are believed to have developed from earlier forms during the

history of the earth" but more generally it is the gradual development of something, quoting in example: "the forms of written languages undergo constant evolution. When we come to discuss gene culture coevolution, these two meanings will come into direct conflict. "It's etymology underlies this ambiguity arising early 17th century: from Latin *evolutio* 'unrolling', from the verb *evolvere* (evolve). Early senses related to movement, first recorded in describing a 'wheeling' manoeuvre in the realignment of troops or ships. Current senses stem from a notion of 'opening out', giving rise to the sense 'development'.

Charles Darwin used the word in print once only, in the closing paragraph of "The Origin of Species" (1859), and preferred *descent with modification*, in part because *evolution* already had been used in the discarded homunculus theory of embryological development and in part because it carried a sense of "progress" not present in Darwin's idea. But Victorian belief in progress prevailed (and the advantages of brevity), and Herbert Spencer and other biologists after Darwin popularised *evolution*.

Dawkins (1976, 1982) argued that discrete, accurately copied, long-lived "replicators" are necessary for cumulative, adaptive evolution and must have the following characteristics:

Fidelity. The copying must be sufficiently accurate that even after a long chain of copies the replicator remains almost unchanged.

Fecundity. At least some varieties of the replicator must be capable of generating more than one copy of themselves.

Longevity. Replicators must survive long enough to affect their own rate of replication.

Although these statements implicitly assume this process is cumulatively integrative over time, so that snakes do not turn into tigers, thus ensuring the stability of the biosphere over evolutionary and cosmological time scales, this is not specifically expressed and can cause problems when we are dealing with gene culture co-evolution. We know there is a deep truth to this argument because our genomes are full of transposable elements which at all opportunities seek to replicate themselves potentially at the expense of organismic mutation and/or survival. However organisms apply natural and sexual selection as whole genomes and there is more complexity to this picture. Even a simple prokaryote genome that reproduces parthenogenetically will eventually accumulate a lethal load of deleterious mutations by Muller's Ratchet. Hence recombination between genomes is a virtually universal necessary condition, via conjugation plasmids and viruses in prokaryotes and indexed sexual recombination in eucaryotes.

Dawkins argued that individual genes must be seen as the units of selection in evolutionary processes within sexual populations. This is primarily because the other possible candidates, notably whole organisms and groups, do not "replicate." Stephen J. Gould in "Caring Groups and Selfish Genes" (1977), argued that by contrast genes cannot be units of selection because natural selection is not able to "see" (operate on) single genes, only on whole organisms. Lewontin (1970) had argued that natural selection at any level requires variation, heredity and differential fitness. Hull argued that people had been packing into one concept, "unit of selection," criteria associated with two distinct and equally important roles:

Replicator: an entity that passes on its structure largely intact in successive replications.

Interactor: an entity that interacts as a cohesive whole with its environment in such a way that this interaction causes replication to be differential.

Wilson DH et al. (2014) in noting that humans possess great capacity for behavioural and cultural change, but our ability to manage change is still limited have set out to sketch a basic science of intentional change centred on evolution, introducing a further set of concepts related to cultural evolution:

The human capacity for symbolic thought provides an inheritance system having the same kind of combinatorial diversity as does genetic recombination and antibody formation. Taking these propositions seriously allows an integration of major traditions within the basic behavioral sciences, such as behaviorism, social constructivism, social psychology, cognitive psychology, and evolutionary psychology, which are often isolated and even conceptualized as opposed to one another.

In this sense, a network of symbolic relations that regulates behavior is like a genotype that produces a phenotype. We will call it a "symbotype" to stress the comparison. Like genotypes, symbotypes evolve based on what they cause the organism to do, regardless of the direct correspondence between the mental and environmental relations. As an example, religious and superstitious beliefs might not correspond directly to anything that exists in the real world, but they might still be favored by selection, based on the behaviors they motivate in the real world. ... The term symbotype refers not to a single cultural trait but rather to a given set of symbolic relations, which results in an entire suite of phenotypic traits (the phenotype). The term does not presuppose any particular proximate mechanism for the symbotype and does not assume that the phenotype can be atomized into independent traits. Obviously, a great deal of future research will be required to clarify the concept of the symbotype, but it differs importantly from the concept of a meme.

Wilson et al. then cite informational recombination as a key generator of variety, that we have seen in the context of integral genetic evolution. While this is true, it goes little or no way towards establishing the integral stability over long time scales of such processes:

Genotypes, symbotypes, and antibodies share something else – almost infinite variety, based on the recombination of their elements. Much as x genes with two alleles at each locus result in 2^x combinations, each potentially producing a different phenotype for selection to act on, a human symbolic system consisting of a few handfuls of “object→sign” relations will be able to derive thousands of combinations, each potentially resulting in a different phenotype for selection to act on (Deacon 1998).

This provides Wilson et al. with their primary thesis that humans have evolved a “quantum leap” in our elaborate capacity for open-ended behavioural and cultural change:

However our symbolic inheritance system and its combinatorial properties arose, the result was a quantum jump in our capacity for open-ended behavioral and cultural change. The best way to see this is by standing back from the “trees” of single scientific studies to see the “forest” of human evolution. A single biological species spread out of Africa to inhabit the globe, adapting to all climatic zones and occupying hundreds of ecological niches, in just tens of thousands of years. Each culture has mental and physical toolkits for survival and reproduction that no individual could possibly learn in a lifetime. Then the advent of agriculture enabled the scale of human society to increase by many orders of magnitude, resulting in mega societies unlike anything our species had previously experienced. The human cultural adaptive radiation is comparable in scope to the genetic adaptive radiations of major taxonomic groups such as mammals and dinosaurs (Pagel & Mace 2004). What else is required to conclude that humans have an elaborate capacity for open-ended behavioral and cultural change?

In this they implicitly acknowledge that not only does the cultural milieu not necessarily optimise natural evolutionary fitness in the biosphere, but that natural fitness cannot now even be defined as an entity in its own right:

It is important to stress that the cultural inheritance system does not entirely supersede the other inheritance systems. ... Moreover, the four inheritance systems – genetic, epigenetics, learning, and symbolic thought – have been interacting with one another throughout our history as a species. Genetic evolution and cultural evolution have been shaping each other for a very long time. It is therefore incorrect to say that cultural evolution serves to maximize genetic fitness, as if the latter can be defined without reference to the former.

So we come back to the central question – how does the advent of cultural evolution enhance or diminish that capacity of Homo sapiens to survive on evolutionary time scales in the closing circle of the evolving biosphere?

Because the concept of symbotype bears a superficial resemblance to the concept of meme (Dawkins 1976), a brief comparison is in order. The term meme is sometimes used broadly to refer to any cultural trait. More narrow usages suggest that cultural traits resemble physical genes in various respects, such as functioning as “replicators,” having a physical form inside the brain, or having the capacity to spread at the expense of their human hosts (Aunger 2002; Blackmore 1999). The most recent treatments of cultural evolution recognize the need for a term that describes cultural traits at the phenotypic level; but these treatments depart from other specific concepts that have been associated with the term meme. In particular, it is possible for the replication of cultural traits to be a systemic process without the need for gene-like replicators (Henrich et al. 2008; Laland & Brown 2002). The concept of “evolution without replicators” applies even to genetic evolution (Godfrey-Smith 2000).

They hint at a deep analogy between genetic and cultural evolution:

The human capacity for symbolic thought provides an inheritance system having the same kind of combinatorial diversity as does genetic recombination and antibody formation. Taking these propositions seriously allows an integration of major traditions within the basic behavioral sciences, such as behaviorism, social constructivism, social psychology, cognitive psychology, and evolutionary psychology, which are often isolated and even conceptualized as opposed to one another.

This merely highlights a deep analogy between cultural ‘inheritance’ and the recombinational complexity of genetic, antibody systems and symbolic thought, but this is not a model for evolution but simply sexual recombination, leaving aside gradual evolutionary change on cosmological time scales due to mutation and selective advantage. Only when we have informational systems which can (1) replicate, (2) be subject to incremental change that is subject to phenotypic differences and selection and (3) the capacity for recombination can we establish a sustainable evolutionary paradigm.

Their answer thus leads to a series of troubling questions regarding not only the lack of a comprehensive integral evolutionary paradigm of gene-culture co-evolution but to the emergence of forms of “evolution” with neither replicators, nor integral stability, and not only in cultural evolution alone, but in genetic evolution as well.

Henrich et al. (2008) state:

While we agree that the existence of replicators is sufficient for cumulative adaptive evolution, they are not necessary. Any process of cultural transmission that leads to accurate replication of the average characteristics of the population will work. Accurate replication at the level of the gene (or meme) will have this effect, but accurate at the population level can arise for other reasons as well. ... Highly accurate, unbiased, genetic replication allows minute selective forces to generate and preserve adaptations over millions of years. Error prone cultural replication, [of one of two mental representations], even when "corrected" by a conformist bias [a group choosing the most common option found in the group], imposes modest, but still significant forces on the cultural composition of the population. Similarly, blending inheritance [e.g. in which an average result not actually present in the set of instances] rapidly depletes the variation in a population necessary for selective processes like prestige-biased transmission to have an effect. But, because the inferential processes that underlie cultural transmission are noisy, it is likely that they can maintain lots of variation. However, this also means that they are likely to create evolutionary forces that act to change the mean, and thus compete with selective forces.

Laland & Brown (2002) take issue with the concepts of replicator versus vehicle, in the context of cultural evolution:

The approach, advocated by Hull (2000)⁴⁷, is to describe as replication all cases in which information is passed along largely unchanged regardless of whether the substrate is a brain or artefactual. Replicators are distinguished from interactors (loosely synonymous with Dawkins' 'vehicles'), which are the entities that exhibit adaptations, but are characterized by a loss of information. They also deal with the continuous interactive aspects of cultural evolution:

*A major question mark against memes, to which both Dawkins and Dennett allude, is whether they have sufficiently high copying fidelity, or accuracy of reproduction. When discussing meme fidelity Dawkins confesses 'here I must admit that I am on shaky ground' (1976, p. 209), and he acknowledges, as an example, that his ideas published in *The Selfish Gene* resulted from a blending of Trivers's and his own memes. Similarly, Dennett (1995 355) asks: 'Isn't one of the hallmarks of cultural evolution and transmission the extraordinarily high rate of mutation and recombination?'. If memes are constantly passed on in altered forms, can they be described as replicators? This looks quite unlike the particulate, virtually error-free copying of gene translation. At first sight, meme evolution appears so fluid, subject as it is to continuous mutation, blending of memes, and cross-fertilization between lineages, that it is difficult to see how it could generate complex adaptations analogous to the vertebrate eye or hand.*

There are at least two counterarguments that have been put forward. The first was expressed most clearly by Dawkins: It is possible that this appearance of non-particulate is illusory, and that the analogy with genes does not break down. After all, if we look at the inheritance of many genetic characters such as human height or skin colouring, it does not look like the work of indivisible and unblendable genes. (1976, p. 209). The second counterargument is that, while every version of a meme varies from one person to the next according to each individual's personal experiences, all memes have a core element that is shared knowledge.

Godfrey-Smith (2000) critiques the classical concept of the replicator in the light of a series of criticisms including those of developmental systems theory:

Criticism of the Dawkins/Hull replicator is found in the work of Paul Griffiths and Russell Gray (1994 298), who are among the proponents of "developmental systems theory" (DST) as a general approach to development and evolution. According to Griffiths and Gray, the replicator/interactor distinction is the product of a "dichotomous" view of evolution and development, where the "dichotomy" involves an illegitimate division between two fundamental types of developmental causes, the "genetic" and the "environmental." Griffiths and Gray claim that the standard replicator/interactor distinction is a "projection into evolution" of dichotomous views of development. ... The developmental systems theorists argue that the only thing which actively replicates or reproduces itself is the entire life cycle. They also argue that the life cycle is the relevant unit for evolutionary theory: "the prime unit of evolution (unit of self-replication) is the developmental process, or life cycle." We should conceive evolution as the "differential replication of developmental processes/life cycles".

He then applies Lewontin's formulation for Darwinian evolution which does not specifically cite a replicator:

Let us approach this point via Lewontin's formulation of the recipe for Darwinian evolution (1970). Evolution requires a population in which there is variation in phenotype, differential reproduction on the basis of phenotype, and heredity of the traits associated with differential reproduction. Heredity is conceived as a correlation between parents and offspring. As Lewontin says, it does not matter how the correlation is achieved, so long as it exists.

In Lewontin's 1970 discussion, the term "unit of selection" has a simple and thin sense -- the units are just the entities in the population which satisfy his three conditions. These "units" need not be replicators, because in a sexual population there can be a great deal of difference between parent and offspring. Yet if parent and offspring are correlated -- if parent and offspring are more similar than randomly selected pairs of individuals in that population -- then evolution by natural selection can occur. The

⁴⁷ Organisms are commonly regarded as: (1) phenotypes that interact with their environments, that survive, reproduce, and pass on genes and (2) the entities that are 'produced' by genes. Hull (personal communication) argues that his notion of 'interactor' is significantly different from Dawkins' 'vehicle'. As in (1), Hull's regards his concept as a populational notion (the population of entities that directly interact with the external environment), while Dawkins's 'vehicle', as in (2), is regarded as more embryological (vehicles are the entity that replicators produce).

requirement of heredity in traits affecting fitness is weaker than a requirement that there exist replicators, and heredity is all that is needed for evolution.

The principle of integral evolutionary change is thus reduced to the simple root of heredity⁴⁸, much as in Gregor Mendel's (1866) work. But this studies hybridisation and is thus about indexed recombination across a single generation and thus gives no theoretical model for integral evolutionary change that ensures stability over the cosmological time scales required for avoiding a Fermi paradox extinction.

This is inadequate and symbolises the entire dilemma of memetic cultural evolution being called evolution at all, because the foundation of evolutionary viability on cosmological time scales is the gradual cumulative change of what Darwin called "descent with modification", now known to be caused by intermittent mutational changes at a low level each generation, enabling the genomes of a species to survive on a population scale combined with natural and sexual selection that is the process occurring on cosmological time scales, that has allowed the biosphere to evolve without Fermi paradox, caused by short-term instability. Recombination, as associated with cross-fertilisation of ideas is a single step process to offset Muller's ratchet and provides non of the graduated change to maintain cumulative evolutionary synchrony between evolving species.

The only way this can be resolved to ensure biospheric and human survival is gene-culture-biosphere co-evolution, in which cultural memes acknowledge the cosmological necessity of human genetic and cultural evolution maintaining overall genetic fitness of the biosphere over such cosmological time scales.

Sexual Selection is a Conscious Creative Process

Sexual selection is a conscious process driven by subjective perception and volition. In spiders, birds and humans the female, who because of a much higher parenting investment in eggs and mammalian pregnancy, frequently evolves forms of conscious choosiness that require a male to be able to fulfil diverse physical and behavioural demonstrations of ability, as a genuine indicator of fitness. These exemplify some of the most creative aspects of evolution that have also had a pivotal influence in human intelligence and cultural emergence (see [fig 131](#)), where astute female reproductive choice driven by extreme sexual polarisation of reproductive investments in humans due to the demands of human pregnancy.

This is the hand of the "Great Mother of All Living" declaring that the evolution of the entire Tree of Life is natural and partly driven by subjective conscious perception and volition. It is sealed in our genes and in the most ancient layers of the Earth's crust. She leaves her signature in the rocks, in the fossils, in the genetic sequences and in the free flowing phenotypes of organismic regulation. There is no way this founding story of our becoming, the core creation myth of our very existence, can be undone.

Here follow the essential principles:

(1) The natural conclusion of evolutionary biology is that conscious evolution began with the eucaryote endo-symbiosis freeing the cell membrane for quantum sentience and social signalling, so we have to understand how natural selection works seamlessly with consciousness in amoeba-flagellates because they conserved conscious volition for a billion years before brains evolved.

(2) One can take a materialistic view that single celled eucaryotes are just sophisticated automata but that flies in the face of the fact that the same excitation processes in them occur in our neurons and phagocytes. In particular, cellular sentience is at the quantum level sensitively detecting small electrochemical fluctuations, light, physical oscillations and chemical orbital effects corresponding to our existing senses. Moreover a transition would take such responses from procaryote genetic operons to non-linear responses to edge of chaos excitations, justifying the notion of conscious perception. Moreover organisms like Dictyostellium show distinct transitions from the free swimming

⁴⁸ **heredity** (n.) "the passing on of physical or mental characteristics genetically from one generation to another" Etym. 1530s, "inheritance, succession," from French hérité, from Old French *eredite* "inheritance, legacy" (12c.), from Latin *hereditatem* (nominative *hereditas*) "heirship, inheritance, an inheritance, condition of being an heir." Legal sense of "inheritable quality or character" first recorded 1784; the modern biological sense "transmission of qualities from parents to offspring" seems to be found first in 1863, introduced by Herbert Spencer.

cellular form of volition to resonant coordinated organismic behaviour in the worm stage of fruiting, showing collective resonant excitation and decision-making characteristic of conscious volition.

(3) Natural selection has to operate at the genetic level and the only way conscious volition can directly influence genetics is through reproductive choice, so conscious evolution becomes the province of sexual selection while environmental natural selection is a mix. This becomes clear in vertebrate and mammal behaviour where sexual selection is the climax process determining evolution of the brain.

(4) This is strongly exemplified in humans, where the female parenting strategy delivering live young via a risky pregnancy and long-term lactation and child rearing is in stark conflict with the male sowing wild oats strategy and the emergence of human intelligence appears to have resulted from neither sex having the upper hand, requiring each to run a red queen evolutionary race of genetic and social intelligence to survive, interrupted only recently by the patriarchal imperative due to male paternity uncertainty.

(5) The key implication is that it is volition and reproductive decision-making and its support in healthy survival in nature that drives what is not just conscious evolution but volitional evolution.

The fact that human culture doesn't yet recognise the huge significance of sexual selection underscores humanity's failure to appreciate conscious volitional evolution, exacerbating the error of materialistic neuroscience failing to recognise conscious volition at all.

Fig 113: Sexual selection in birds and spiders. Sexual selection is almost universally consciously engendered, while natural selection is only partially so, because some natural selection factors are inanimate, while other animate interactions with predators and prey and social interactions are consciously based. Sexual selection enables the female who has to invest much more in eggs than the male evolves to use creative conscious perceptual means to assess genuine indicators of male genetic and/or parenting fitness. This can lead to a runaway Red Queen effect (Ridley 1993), driven by female reproductive choice evolving to become more choosy, as male adaptations become more attractive resulting in beautiful bird plumages (Prum 2017, Jabr 2019). How beautiful they have become attests to the fact that the female bird perceives it and demands it in the same kind of detail we find spell-binding. Top row: the Superb Lyre bird, which in addition to having a mesmerising tail and bridal veil like the peacock (lower right), is required to literally mimic every sound from other birds to chainsaws and construction sites to a squalling baby (1, 2, 3, 4) seducing the female with every sound in the universe surrounding them. Lower left, the Satin bowerbird courtship involves complex two-stage cues in female reproductive choice (Robson et al. 2005). Male South African Weaver Birds similarly construct elaborate hanging nests which avoid predators, to attract mates (fig 141). Lower centre: Peacock spider courtship. The male has to carefully signal with his hairy mid legs from under her leaf to seduce her willingness to mate, rather than eat him, before fertilising her with his palps. These spiders are tiny and have even tinier brains as the inset on a human finger shows.

Evolutionary Origins of Neuronal Excitability, Neurotransmitters, Brains and Conscious Experience

The discussion of psychedelics in the previous chapters brings us back to a fundamental question. Why does the brain use neurotransmitters such as serotonin in such characteristic ways to do with emotion, wakefulness and sleep, vigilance and reward? This takes us back all the way to the emergence of life and potentially to the cosmological relationships defining the biomolecules, from ATP to RNA, and the various biological amino acids and their elementary amines such as tryptamine and dopamine. The elementary neurotransmitter types, many of which are fundamental amino acids (glutamate, glycine, GABA), or amines derived from amino acids (serotonin, dopamine, histamine, epinephrine) have primordial relationships with the membrane, as soluble molecules with complementary (+) charge relationships with the hydrophilic (–) ends of the phospholipids. Glutamate and GABA are prominent components of both the Tagish Lake and Murchison carbonaceous chondrites and stardust aerogels from the tail of comet Wild 2, clear evidence for a prebiotic cosmological status. As the two key excitatory and inhibitory neurotransmitters in the human brain, which are also key in myxamoeba fruiting body aggregation, demonstrating their strong conservation, this also gives human consciousness a cosmological foundation.

Tryptophan, the amino acid from which serotonin is generated, plays a key role in the transfer of electric charge in the earliest forms of photosynthesis. In *Rhodobacter sphaeroides*, there are 39 tryptophan residues surrounding the porphyrin centre. Initiation of the electron transfer reaction by excitation results in a transient change in the absorbance at UVB, near the peak of the tryptophan absorbance band. To make serotonin from tryptophan, oxygen is needed, and in the earliest geological times the Earth's atmosphere had little oxygen. Thus, serotonin is made specifically in unicellular systems capable of photosynthesis and the cellular production of oxygen. Consequently serotonin is up to 100 times more plentiful in plants and animals have ceased to synthesise tryptophan, depending on plants for their supply. This relationship with light continues to this day in human use of melatonin to define the circadian cycle and serotonin in wakefulness and sleep, with light deprivation causing depression through serotonin.

Fig 114: Murchison amino acids. Biological blue/purple. Neurotransmitters red/purple.

The fundamental components of the mammalian G-protein coupled receptor system, including the canonical GPCR itself appear to go right back to LECA the last eucaryote common ancestor, fig 115, as they are shared across all major eucaryote branches (Mendoza et al.). From the gene diversity for serotonin receptors, the 5-HT_{1a} receptor is estimated to have evolved 750 million to 1 billion years ago, before the muscarinic, dopaminergic and adrenergic receptor systems (Peroutka & Howell, Peroutka, Walker et al) and long before the Cambrian radiation defining multicellular animals. As noted by Natch (1973), "the ionic mechanisms for electrogenesis are basically identical to those in nerves, muscles, and receptors of metazoan organisms".

| Amino acid | Murchison meteorite | Electric discharge |
|--------------------------------|---------------------|--------------------|
| Glycine | 4 | 4 |
| Alanine | 4 | 4 |
| α -Amino-n-butyric acid | 3 | 4 |
| α -Aminoisobutyric acid | 4 | 2 |

| N-Methylalanine | 2 | 2 |

Wan & Jékely (2021) describe the ancestral repertoire of eukaryotic excitability and discuss five major cellular innovations that enabled its evolutionary origin, including a vastly expanded repertoire of ion channels, the emergence of cilia and pseudopodia, endomembranes as intracellular capacitors, a flexible plasma membrane and the relocation of chemiosmotic ATP synthesis to mitochondria, which liberated the plasma membrane for more complex electrical signalling involved in sensing and reacting.

This places the emergence of receptor proteins and their neurotransmitters as occurring before the multicellular nervous systems, as cell-to-cell signalling molecules essential for survival, and positive and negative responses to nutrition and danger. The need for multimodal molecular messengers thus arises from the need for cells to have a variety of signalling molecules modulating key motivational and aversive aspects of survival strategy. It explains that neurotransmitters originated from direct signalling pathways between the cell membrane and gene expression in the nucleus of single cells, highlighting why changes in gene expression such as that of *egr-2* in psychedelics may be central to psychedelic neurotransmitter action, rather than just flow-on excitation. It has been suggested that key enzymes in neurotransmitter pathways may have become ubiquitous through horizontal gene transfer from bacteria (Iyer et al).

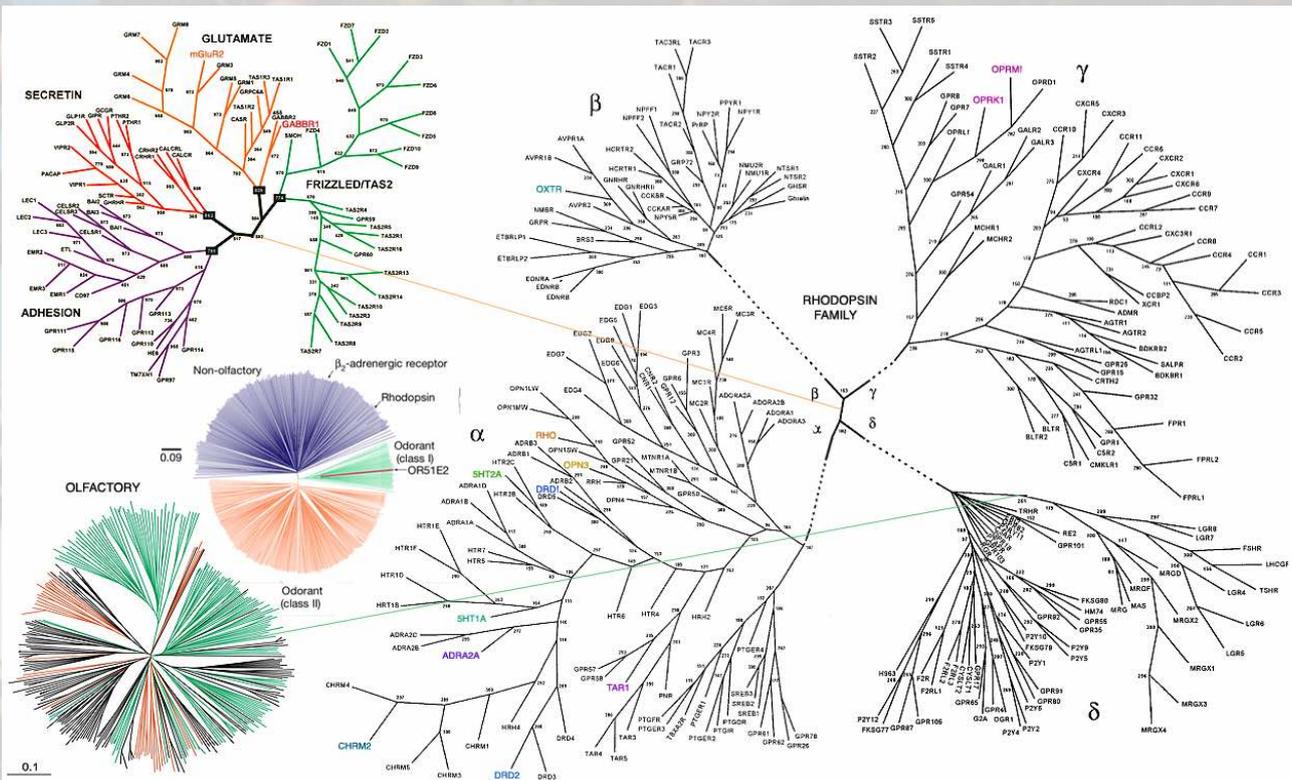

Fig 115: (Left) Evolutionary tree of the human G-protein linked receptors (Fredriksson et al. (2003), with examples highlighted in color. On the α branch are amine receptors - serotonin 5HT1A and 5HT2A, dopamine D1, and D2 (DRD1, DRD2), adrenergic α 2a (ADRA2A), muscarinic acetylcholine (CHRM2), trace amine TAR1, as well as rhodopsin (RHO) and enkephalin (OPM3). On the glutamate branch are metabotropic glutamate mGluR2 and GABA GABBR1. On the β branch is oxytocin (OXTR) surrounded by vasopressin receptors and Ghrelin. On the γ branch are opioid κ and μ (OPRK1, OPRM1). Olfactory (Zozulya et al 2001, Billesbølle et al. 2023) and the non-rhodopsin receptors are linked to their respective points on the rhodopsin family tree.

This ancient origin is confirmed by the fact that receptor proteins, second signalling pathways and key neurotransmitters are known to occur widely in single-celled protists. Both *Crithidia* and *Tetrahymena* contain norepinephrine, epinephrine, and serotonin (Blum 1969). The ciliated protozoan *Tetrahymena pyriformis* (Brizzi & Blum, Essman) and flagellated *Crithidia fasciculata* (Janakidevi et al) utilise serotonin, and the former also metabolises dopamine and epinephrine (Takeda & Sugiyama, Nomura et al). *Tetrahymena pyriformis* also has circadian light-related melatonin expression (Kohidai et al). In *Tetrahymena*, intracellular concentrations of serotonin and dopamine vary inversely during logarithmic and stationary phases of growth. These substances are released into the extracellular milieu, probably in response to elevated intracellular Ca^{2+} , where they can increase intracellular levels of cAMP. Evidence that GABA could play a similar role comes from the finding that treatment with diazepam, a GABA receptor ligand, elevates the growth rate of *Tetrahymena* (Lauder 1993). *Tetrahymena* utilises histamine, serotonin, epinephrine, melatonin, and triiodothyronine can be found in it, as well as peptide hormones, such as insulin, adrenocorticotrophic hormone, epidermal growth factor, endocannabinoids, endorphins and c-AMP and GMP. Thus signalling molecules in single celled eucaryotes appear to further long-term adaption through cross-generational epigenetic changes (Csaba 2014).

Trypanosoma cruzi could be induced to differentiate by increased cAMP levels that resulted from addition of epinephrine (González-Perdomo et al). Species of *Entamoeba* secrete serotonin and the neuropeptides neurotensin and substance P (McGowan et al) and release and respond to catecholamine compounds during differentiation from the trophozoite stage into the dormant or transmissible cyst stage (Eichinger et al) and *Plasmodium falciparum* malaria replication can be blocked by 5HT1a agonists (Locher et al). Acetylcholine and its G-protein coupled receptor have been found in acanthamoeba (Baig & Ahmad 2017, Baig et al. 2018) and acetylcholine, vasopressin and opioid systems coordinate contractile vacuoles in *Amoeba proteus* (Bagrov & Manusova 2011). This heightens the dual role of such molecules in both intra- and inter-cellular signalling, just as acetylcholine is both a neurotransmitter and induces the secretion of insulin in humans. Elements of the protein signalling pathways, such as protein kinase C, essential to neuronal synaptic contact originated close to the eucaryote origin (Emes et al. 2008, Ryan & Grant 2009). Likewise the Dlg family of postsynaptic scaffold proteins, which bind neurotransmitter receptors and enzymes into signalling complexes originated before the divergence of the vertebrates and arthropods (Nithianantharajah et al. 2012).

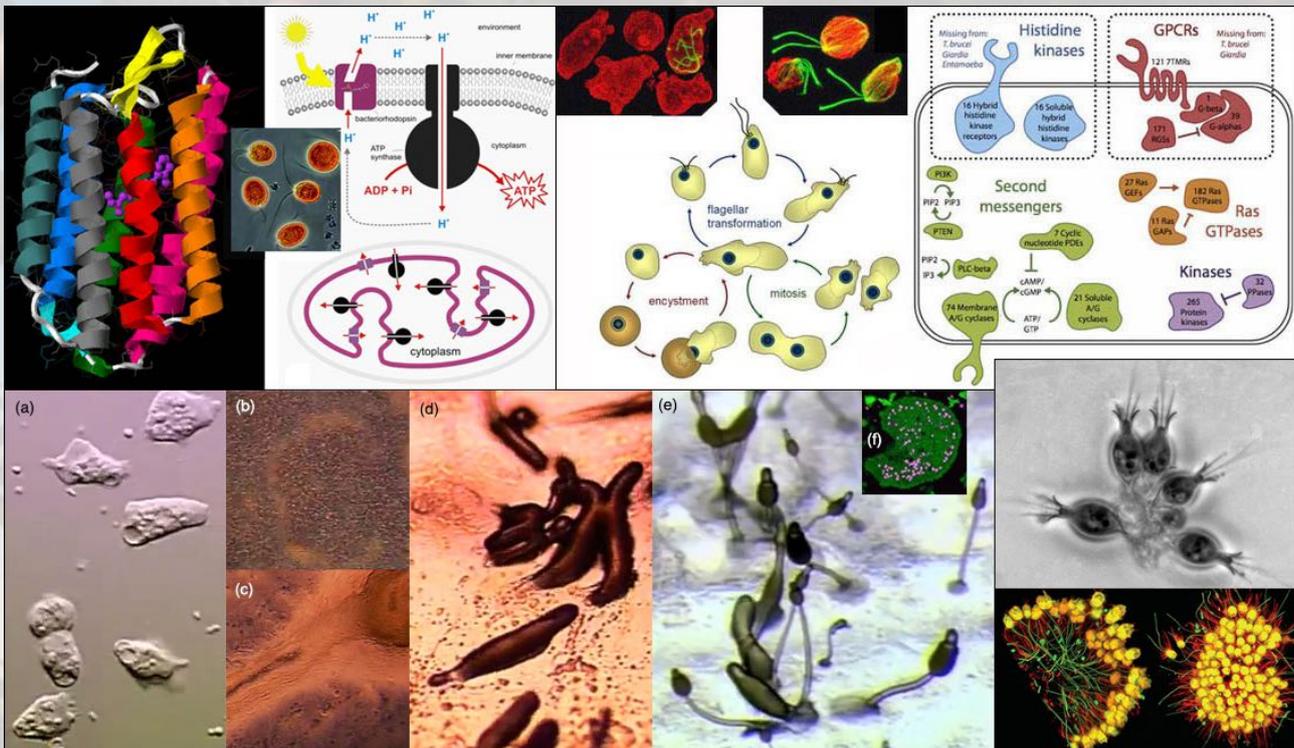

Fig 116: Left: Heptahelical rhodopsin receptor in the G-protein coupled family creates a photosynthetic H^+ ion gradient in *Halobacteria* provides voltage gradient excitability and ATP to power the cell. Centre: Complement of signalling systems found in *Naegleria gruberi* (Fritz-Laylin et al. 2010), a free-living single celled bikont amoeba-flagellate, belonging to the excavate group *Heterolobosea* that diverged from other eukaryotic lineages over a billion years ago, which include some of the most primitive eucaryotes such as *Giardia* and *Trichomonads*. Nevertheless it is capable of both oxidative respiration and anaerobic metabolism and can switch between amoeboid and flagellated modes of behaviour, regenerating complete centrioles and flagellae de novo (Fritz-Laylin & Cande 2010). The *Naegleria* genome sequence contains actin and microtubule cytoskeletons, mitotic and meiotic machinery, suggesting cryptic sex, several transcription factors and a rich repertoire of signalling molecules, including G-protein coupled receptors, histidine kinases and second messengers including cAMP. Apoptotic cell death essential for maintaining multicellular integrity also arose with mitochondrial endosymbiosis (Kaushal et al. 2023), is promoted via the mitochondria, occurs also in single celled eucaryotes (Madeo et al. 1997) and originated in bacterial protection against phages (Koonin & Aravind 2002, Kibby et al. 2023). Lower left *Dictyostelium discoideum* (a) individual cells eating bacteria, (b) aggregation wave front of cAMP, (c) aggregating to form slugs, (d) slugs, each containing 1000 or so individual amoeba, swimming purposefully and making individual chemotactic decisions coordinated through coherent membrane excitability also showing they can merge and separate, (e) fruiting body and (f) sexual syntrium with multiple nuclei, pink (Bloomfield et al. 2019). Lower right: Choanoflagellate cells forming an ancestor of animals, at the transition from single celled organisms to colonies have conserved the amoeboid-flagellate switch (Brunet et al. 2021). Below: The colonial form *Choanoecca flexa* can invert the colonies in a similar way to tissue layer folding in early animal embryogenesis (Brunet et al. 2019).

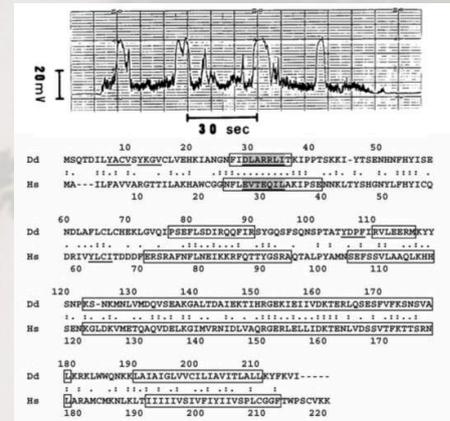

Consequently the major neuroreceptor classes have a very ancient origin, with the 5HT1 and 5HT2 families diverging before the molluscs, arthropods and vertebrates diverged, close to the level of the founding metazoa. Sponges, with only two cell types, express serotonin (Wayrer et al) and have been shown to have the critical gene networks to generate synapses, in a pre-coordinated form (Conaco et al). Coelenterates already have all the key components of serotonin pathways, involved in signalling by sensory cells and neurons, despite having only a primitive nerve network (McCauley, Umbriaco et al).

Aggregation of social myxamoeba such as the slime mould *Dictyostelium discoideum* (video), under exhaustion of food supply, is mediated by cyclic-AMP, also utilising glutamate and GABA_B receptors (Taniura et al. 2006, Anjard & Loomis), forming first a motile slug and then forming a fruiting body via reciprocal serotonin and monoamine oxidase A (maoA) activity (Halloy et al, Goldbeter, Taniura et al, Baskar, Mani & Hyde). MaoA, which degrades serotonin, confers the fate of an organiser to the *Dictyostelium* tip. Once a tip has formed, serotonin contributes to tip dominance. It inhibits further tip formation, and thus ensures the mound retains the size determined during the earlier developmental stage. This relationship between serotonin and MAOa is precisely retained in humans, as exemplified in MAO inhibitor anti-depressants. The slug motions, including phototaxis, follow a distinct dynamical process from individual amoeba responses (Schlenkrich et al. 1995), indicating a separate collective organismic excitation protocol.

And this collective organism can be sexually diverse. *D. discoideum* has three different mating types which can mate with any two different sexes. Heterothallic mating occurs when two or more amoebae of different mating types fuse during aggregation to form a multinuclear syncytium, which then breaks apart forming binucleate cells leading to one or more giant zygotes, which then release cAMP to attract other cells, engulfing them cannibalistically which serve to encase the whole aggregate in a thick, cellulose wall to protect it. Inside the macrocyst, the giant cell divides first through meiosis, then through mitosis to produce many haploid amoebae that will be released to feed as normal amoebae would. This means that the collective organism is sexually diverse, just as we are. It also means that a sexually diverse but significantly related population engages in sacrificial behaviour for the benefit of the species because the individuals forming the stalk die and do not get to produce spores. In related *D. purpureum* the slug stage in genetically mixed colonies separates into slugs containing a majority of closely related individuals to avoid cheating (Mehdiabadi et al. 2009). The fact that syncytium formation leads to cells having up to three mitochondrial genotypes, when three sexual strains fuse, suggests sexual fusion could have evolved by the endosymbionts to ensure their survival, controlled later by sperm-ovum fertilisation to avoid cytoplasmic genetic warfare. Serotonin thus plays a key role in enabling developmental organisation of reproduction conducive to the survival of the collective sexual organism, rather than individual amoebae.

Both serotonin and external cAMP as well as glutamate and GABA are thus involved in social signalling, mediated by external G-protein linked receptors, despite the fact that in mammals cAMP is an intracellular second-signalling molecule. GABA promotes the release of the peptide SDF-2 which induces spore formation. Glutamate acts via the metabotropic glutamate receptor DdmGluPR as a competitive inhibitor of GABA functions mediated by a GABAb-like receptor and is also able to inhibit induction of sporulation by SDF-2. Lack of glutamate expression delayed aggregate formation and impaired chemotaxis toward cAMP. Phylogenetic analysis suggests that DdmGluPR diverged after the mGluR family-GABAb receptors split but before mGluR family divergence (Anjard & Loomis 2006, Milne & Devreotes 1993, Tanura et al. 2006).

Fig 117: Above: Changes in extracellular electric potential of *D. discoideum* pseudoplasmodial slug (fig 116) moving on the substratum (Kitami 1988). Below: VAMP homology between *Dictyostellium* and humans (Bennett et al. 2008).

About a third of wild-collected *D. discoideum* also engage in the symbiotic "husbandry" of bacteria, allowing the "seeding" of the food source at the location of the spore dispersal, which is particularly valuable if the new location is low in food resources. Colonies produced from the "farming" spores also show the same behaviour when sporulating. Some bacteria are sequestered in double membrane bound phagosomes where they are protectively isolated but not consumed. The amoebae preserve their individuality and each amoeba has its own bacterium. Symbiotic farming has a cost benefit trade-off: Those colonies that do not consume all of the prey bacteria produce smaller spores that cannot disperse as widely. In addition, much less benefit exists for bacteria-containing spores that land in a food-rich region, explaining why an ongoing minority of colonies do this (Brock et al. 2011).

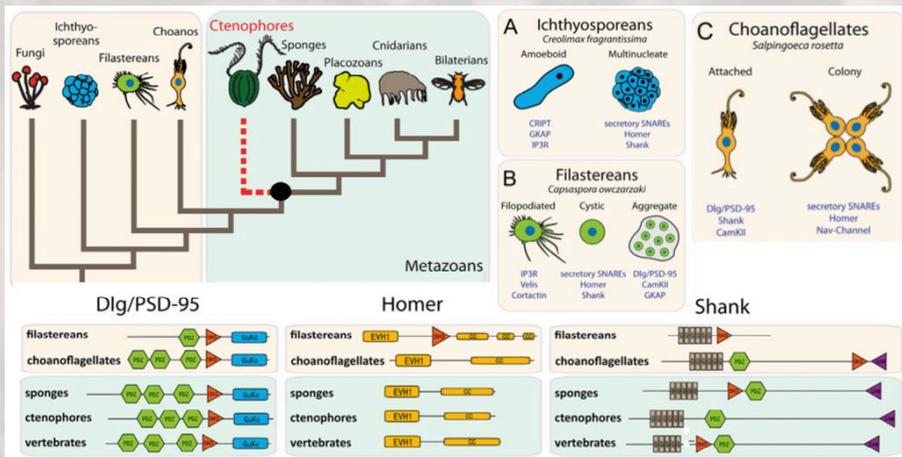

Fig 118: Ichthyosporeans Filasterians and Chonaoflagellates have genes for proto-synaptic proteins having extensive evolutionary homology with metazoan and vertebrate (human) synaptic proteins Dlg/PSD-95, Homer and Shank. In single-celled species they are associated with aggregation processes, just as human synaptic protein Dlg/PSD-95 is also active in septate junctions in skin cells (Burkhardt & Sprecher 2017).

Just as humans and slime moulds share the same basic

neurotransmitter pathways, human phagocytes and *Dictyostelium* share the same pathways for bacterial assimilation and defensive protection (Dunn et al. 2017). This is reflected in the homology of human and myxamoebic SNARE protein VAMP7, or SYBL1 (Bennett et al. 2008), involved in both endosomal vesicle transport and target cell killing by natural killer cells. Syntaxin 7, syntaxin 8, Vti1 and VAMP7 form an active SNARE complex for early macropinocytic compartment fusion in *Dictyostelium* (Bogdanovic et al. 2008). Syntaxins drive fusion of synaptic vesicles containing v-SNAREs. and interact with voltage dependent calcium and potassium channels. The myxamoebic versions likewise have sequence homologies with human versions.

Studies of protists that are close relatives of metazoans, like the ichthyosporean *Creolimax fragrantissima*, the filasterean *Capsaspora owczarzaki* and the two choanoflagellate species *Monosiga brevicollis* and *Salpingoeca rosetta* possess proto-synaptic proteins – synaptic protein homologs although they never developed synapses and neurons that may interact with other proto-synaptic proteins in organisms with no synapses and neurons, in a very similar manner as observed in neurons. Their genomes encode for Dlg/PSD-95, Homer and Shank. Vesicle membrane proteins (e.g. Synaptophysin and Synaptogyrin), proteins involved in exocytosis (e.g. Complexin), and signaling (e.g. CaMKII) are also present in the genomes *C. owczarzaki* and choanoflagellates. Moreover, voltage-gated sodium and calcium channels were identified in the genomes of choanoflagellates (Liebeskind et al. 2011, Burkhardt & Sprecher 2017).

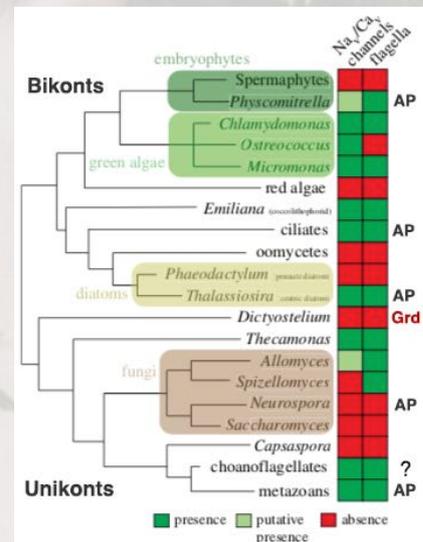

In metazoans with synapses and neurons, synaptic proteins are functionally diverse and fulfil different roles in other cell types. This seems to be the case for nearly every synaptic protein found in vertebrates. For instance, Dlg/PSD-95 functions as a scaffolding protein and clusters iGluRs to the plasma membrane of postsynapses, but the same protein is an important component of septate junctions in epithelial cells. The protein Homer, which is expressed in the nucleus and binds both to flotillins in choano-flagellates and to astrocytes in vertebrates highlighting that many proto-synaptic genes may be pleiotropic.

Fig 119: Both action potentials (AP) and Na/Ca ion channels capable of delivering them are widely spread across the eucaryote tree, leading to the notion that the founding ciliated eucaryote possessed action potentials. Notably *Dictyostelium* lacks flagella and has graded membrane potentials (Brunet & Arendt 2016).

Brunet & Arendt (2016) have explored the incidence of action potentials and Na/Ca ion channels and associated the incidence of action potentials in single celled eucaryotes as stemming from the activation of the eucaryote flagellum. The eucaryote kingdom is divided at or close to the base by the unikont/ bikont division of one or two flagella, with animals and plants on opposing branches. Both of these broad groups bear flagella and have action potentials. Close to the root excavata such as *Naegleria* are known to possess flagella (fig 116). From this point of view excitability including that leading to action potentials is an ancestral feature of flagellated energetic protists. The amoeboid-flagellate switch is also conserved across the choanoflagellates, leading to metazoa (Brunet et al 2021).

Wan and Jékely (2020) note that fast reaction escape responses of ciliated eucaryote cells such as *Paramecium* (Schlaepfer & Wessel 2015) to potential threats from illumination changes or mechanical disturbance are usually induced by action potentials – unidirectional electrical pulses involving fast, regenerative changes in membrane potential. They state that while all cells display some electrical activity, phylogenetic evidence suggests that the capacity to propagate action potentials may have been an ancestral eukaryotic trait supported by LECA.

Brunet & Arendt (2016) advance an evolutionary hypothesis for the origin of the depolarization–contraction–secretion (DCS) coupling, the functional core of animal neuromuscular circuits. They argue that such fast reactions may have emerged in response to accidental membrane damage and sudden calcium influx. Based on calcium-triggered membrane depolarization, they infer that the first action potentials evolved alongside the membrane of sensory-motile cilia, with the first voltage-sensitive sodium/calcium channels enabling a fast and coordinated response of the entire cilium to mechanosensory stimuli. From the cilium, action potentials then spread across the entire cell, enabling global cellular responses such as concerted contraction in several independent eucaryote lineages. In animals, this process led to the invention of mechano-sensory contractile cells. These gave rise to mechano-sensory receptor cells, neurons and muscle cells by division of labour and can be regarded as the founder cell type of the nervous system.

A precursor of synaptic transmission occurs in choanoflagellates, where the cells of some species aggregate to form colonies. In these colonies, the cells move water past the colony by beating their flagella. Each of these cells can release transmitters that act on receptors in nearby cells to produce movements of the whole colony (Kristan 2016). At the transition to multicellularity, the fresh water sponge *Spongilla lacustris* has 18 distinct cell types. Synaptic genes were active in a few of these types, which were clustered around the sponges' digestive chambers called secretory neuroid cells. X-ray scans revealed that neuroids send out long arms to modulate the activity of choanocytes holding the flagella that drive the sponges high-flow filter feeding currents. They do not have actual synapses but illustrate the evolution of cells specialising in modulating the activity of others (Musser et al. 2021).

Also originating with LECA are key transcription factors responsible for initiating transcription and hence gene expression. Fig 120(1) shows the full spread of these factors across eucaryote diversity, with a large paneucaryotic core complemented by further evolution of TF's in unikonta, holozoa (animals and amoebas), metazoa (higher animals), fungi, algae and higher plants. Likewise, the homeodomains (Bürglin & Affolter 2016) originate at or close to the LECA root (Derelle et al. 2007), occurring for example in trichomonads and more diversely in amoebzoa and establishing separate new branches in metazoa, fungi and plants. These provide a genetic skeleton for developmental adaption of higher organisms through regulatory changes of morphogenesis leading to evolution of organismic phenotype of major phylla in constrained forms of regulatory evolution leading to among other branches to the brains of vertebrates, mammals, primates, apes and humans in the processes outlined in fig 120.

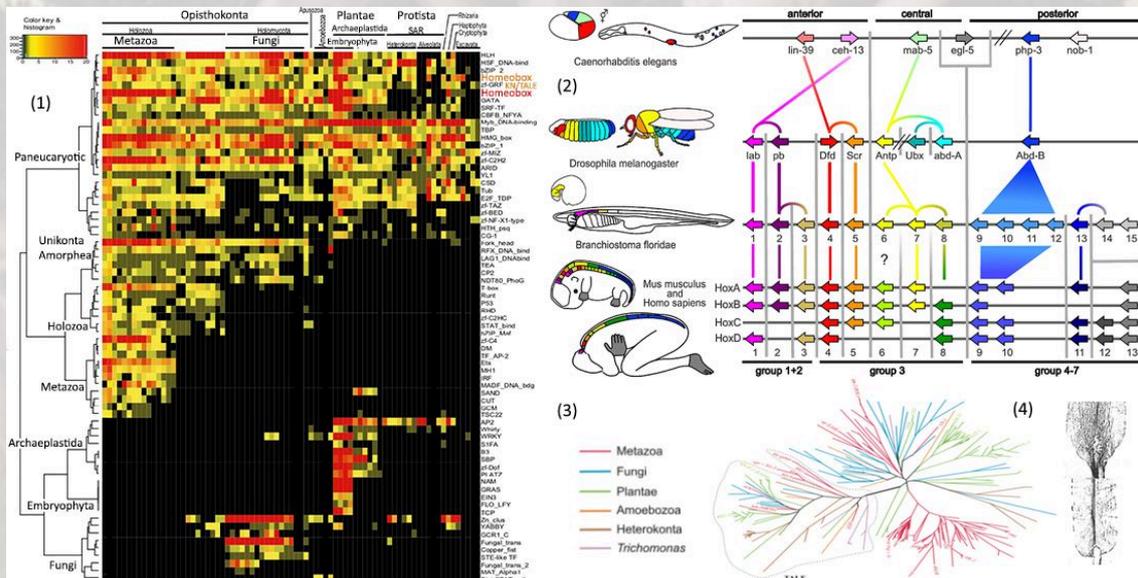

Fig 120: (1) Transcription factors, including homeobox motifs in homeotic genes are widely distributed across the eucaryotes, indicating an origin with LECA (de Mendoza et al. 2013). Separate groups have also evolved in plants animals and fungi. Short terminal repeats representing about 5% of human DNA appear to act as mutable transcription factor "wells" flanking core regulatory sequences that allow a population of transcription factors to collect TFs to effect modulated gene control (Horton et al. (2023). (2) Related homeotic genes are involved in segmentation of both arthropods and vertebrates and also occur in plants (4). (3) Evolutionary tree of homeodomains shows these arose in single celled eucaryotes and diversified in metazoa, fungi and plants (Derele et al. 2007). Evolutionary developmental biology (evo-devo) compares the developmental processes of different organisms to infer how these evolved. It is composed of multiple core evolutionary concepts. (a) Deep homology is the finding that dissimilar organs such as the eyes of insects, vertebrates and cephalopod molluscs, long thought to have evolved separately, are controlled by similar genes such as pax-6 (see fig 154). These genes are ancient, and highly conserved among phyla; they generate the patterns in time and space which shape the embryo, and ultimately form the body plan of the organism. (b) Species do not differ much in their structural genes, such as those coding for enzymes; what does differ is the way that gene expression is regulated by the toolkit genes. These genes are reused, unchanged, many times in different parts of the embryo and at different stages of development, forming a complex cascade of control, switching other regulatory genes as well as structural genes on and off in a precise pattern. This multiple pleiotropic reuse explains why these genes are highly conserved, as any change would have many adverse consequences which natural selection would oppose. New morphological features and ultimately new species are produced by variations in the toolkit, either when genes are expressed in a new pattern, or when toolkit genes acquire additional functions. Transposable elements facilitate this through modular regulatory changes in how the toolkit is expressed.

A multicellular transition point occurs in Cnidaria such as hydra, where the nervous system is an undifferentiated neural net, yet hydra displays innovative and intuitive multiple modes of locomotion, as shown in fig 256, and cnidaria are fully-capable of associative learning (Botton-Amiot, et al. 2023, Bielecki et al. 2023). This attests to the idea that the neural net is self-organising society of sentient amoeboid-flagellates, rather than the neurons being relatively trivial

integrators, and the neural net / brain design is the causative definer of intelligent consciousness. The emphasis thus remains on cellular rather than network intelligence alone (Ford 2009, 2010, 2017).

We thus now turn to higher organism and particularly human brain development. Late in the fourth week, the neural tube develops three distinct bulges that correspond to the areas that will become the three major divisions of the brain: forebrain, midbrain, and hindbrain. Not until the end of week 5 and into week 6 (usually around forty to forty-three days) does the first (chaotically) excitable electrical brain activity begin to occur. During weeks 8 to 10, the cerebrum begins its development in earnest. Neurons proliferate and begin their migration throughout the brain. The frontal and temporal poles of the brain are apparent during weeks 12 to 16, and the frontal pole (which becomes the neocortex) grows disproportionately fast when compared with the rest of the cortex.

Fig 121: Fetal brain development (Konkel 2018).
Emergence of resting state activity by fMRI
(Schöpf et al. 2012).

The very early leading role in brain development of serotonin expression is laid bare by its sequential expression and elaboration from very early stages and is consistent across vertebrate species. In early mouse embryos, 5-HT derived from the maternal-embryonic circulation activates different 5-HT receptors to control the proliferation, migration, gene expression, and morphogenesis of neural-crest and neural crest-derived cells (Buznikov et al. 2001). 5-HT signalling molecules such as enzymes responsible for 5-HT synthesis and breakdown, 5-HT receptors and the 5-HT transporter (5-HTT) are already expressed in the brain before 5-HT neurons are born (Witteveen et al. 2013).

“The development of serotonin-containing neurons has been extensively studied in a number of animal species, including rat, chick, nonhuman primate, and human. In all species studied the highest functional status of the serotonin system is reached early in development, and adult levels of the system are actually much lower than in the younger animal. Serotonergic neurons are first evident by 5 weeks of gestation and increase rapidly through the 10th week of gestation. By 15 weeks of gestation, the typical organization of serotonin cell bodies into the raphe nuclei can be seen. Serotonin levels increase more slowly throughout the first 2 years of life and then decline to adult levels by 5 years of age. The early arrival of serotonin into target regions, ahead of other monoamines, may regulate the ingrowth and terminal development of other monoamines, in particular dopamine. Because serotonin regulates the maturation of target areas, the amount of serotonin that grows into an area becomes key for further development” (Whitaker-Azmitia 2001).

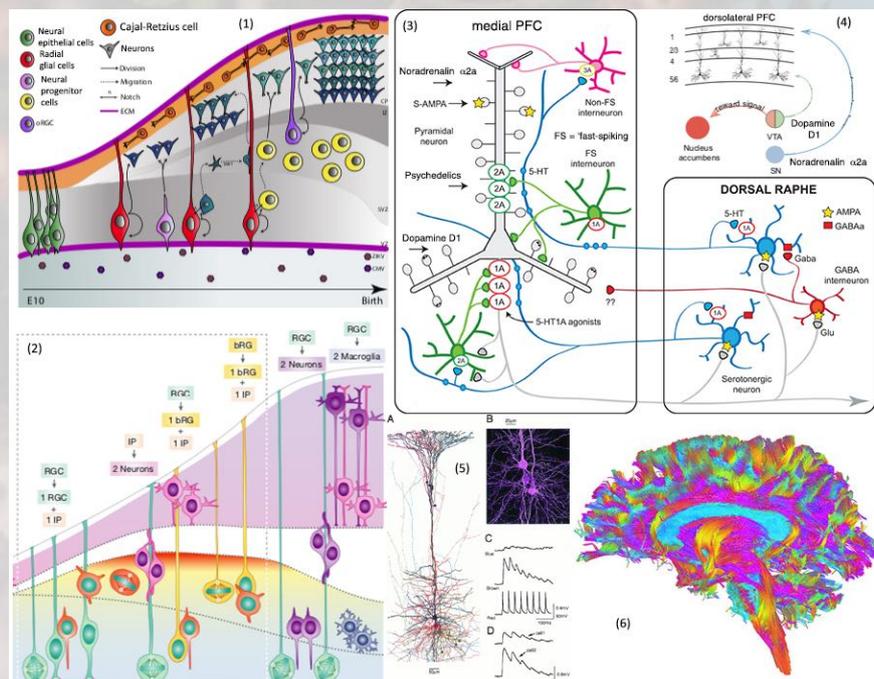

GABAergic neurons likewise appear early in the development of embryonic brain and spinal cord. GABAergic fibers, apparently ascending from the spinal cord, project through regions of brainstem, midbrain and forebrain where serotonergic, dopaminergic and peptidergic neurons are being generated. An example of trophic signalling between neurons and glia also occurs in the serotonergic regulation of the calcium-binding protein S100 β , which functions as a serotonergic and GABAergic growth factor in the embryonic brain stem (Lauder 1993).

“Cells of the serotonergic raphe nuclei are generated early in the embryonic rat brain, prior to most of their target cells. As soon as they are formed, these neurons begin to send axons rostrally, where they soon encounter their earliest targets (e.g., dopamine neurons of the substantia nigra). The ability of 5-HT to regulate development of its target cells may be mediated by specific 5-HT receptor subtypes. It has been demonstrated that prenatal exposure to pCPA, or the general agonist 5-methoxytryptamine (5-MT), alters the postnatal expression of 5-HT receptors in rat brain. A recent in situ hybridization study has revealed that embryonic monoamine neurons and other neuronal populations affected by in utero exposure to pCPA express mRNA transcripts encoding 5-HT1c and 5-HT2 receptors. Moreover, the [psychedelic] 5-HT1c/2 agonist DOI promotes growth of cultured embryonic brainstem 5-HT neurons and mesencephalic dopamine neurons”.

5-HT neurons located in the rostral raphe cluster extend profuse axon tracts into the fore- and midbrain. A distant target of the ascending 5-HT projection system within the forebrain is the medial prefrontal cortex (mPFC). The mPFC is the seat of our highest cognitive abilities and known to be involved in attentional processes, working memory and behavioural flexibility. In rodents, the developing 5-HT-positive fibers reach the mPFC, where they initially innervate the marginal zone and the subplate, before massively innervating the cortical plate proper. The 5-HT fibers, found within the marginal zone of the mPFC, are thought to contact Cajal-Retzius (CR) cells, cortical layer I cells secreting the

glycoprotein reelin crucial for the correct layering of the cortex (Witteveen et al. 2013). Serotonin's key function as an organiser of brain development in humans, may thus explain why foetal alcohol syndrome may be precipitated by embryonic serotonin depletion (Whitaker-Azmitia et al. 1996).

Fig 122: (1, 2) Neurogenesis and cellular migration up the glial scaffold to form the cortical layers (Agirman et al. 2017, Paridaen & Huttner 2014, Liu et al. 2023). (3) Serotonin interactions in the mature brain between the Dorsal Raphe and mPFC (Celada, Puig & Artigas 2013). These are also activated in embryogenesis and mediate the organisation of the layered cortex through the Cajal-Retzius cells. Inset: Dopamine and Noradrenalin inputs to dlPFC (Thiele & Bellgrove 2018). (5) Pyramidal cells are complex oscillating cells which have receptors for multiple neurotransmitters in diverse locations from dendrites to the cell body and axon. (6) Connectome of axonal pathways in the brain emphasises its integrated embryonic development as an adaptive cellular process.

The 5-HT_{2a} receptor develops more slowly than the 5HT_{1a}. The peak of the 5-HT_{2A} receptor is earlier than the 5-HT_{2C} receptor and the receptor is functional by postnatal day 7 in the rat hippocampus. This time period is too late to influence differentiation, however the receptor may play a role in branching, terminal sprouting, synaptogenesis, and mitogenesis. The role of both the 5-HT_{1A} and 5-HT_{2A} receptors during development suggest that the 5-HT_{2A} receptor acts to release glucose from glial cells and to increase Ca²⁺ levels in neurons. These actions destabilise the internal cytoskeleton, promoting fluidity and result in cell proliferation and apoptosis, resulting in structural instability. By contrast, the 5-HT_{1A} receptor increases the release of S100-β from astrocytes and reduces the levels of cAMP in neurons, promoting an acceleration of differentiation produced by enhancement and stabilisation of cytoskeletal formation, neuronal rest and stability. The 5-HT₂ receptor can be referred to as a programmable receptor. Events during development may affect the number, affinity, or function of these receptors in the adult brain. Both prenatal and postnatal stress to the mother significantly increases the number of 5-HT₂ receptors in the offspring, even after they have become adults (Azmitia 2001).

Serotonin neuronal autoregulation spans major metazoan phyla from molluscs, through arthropods to vertebrates as well as the human brain: "Serotonin appears to autoregulate development of cultured 5-HT neurons, and can initiate and autoamplify its own synthesis in hypothalamic cultures. Evidence for an autoregulatory role of 5-HT in vivo comes from the observations that *Drosophila* mutants incapable of 5-HT synthesis, and adult snails depleted of 5-HT, exhibit aberrant growth of serotonergic axons. Similar effects are seen in rats treated prenatally with the 5-HT receptor agonist 5-MT. Taken together, these studies indicate that altered levels of 5-HT may affect development of the serotonergic system in developing brain. Serotonin also inhibits its own growth through the presence of serotonergic receptors on serotonin terminals possibly 5-HT_{1b}. Thus, serotonin regulates not only the development of target fields, but also its own development" (Whitaker-Azmitia et al. 1996).

This picture confirms that the role of serotonin in nervous system development is strongly conserved from amoebozoia to humans and signals the existence of an ancient conserved regulatory system that evolved in single celled eucaryotes to secure survival of the collective organism, still similarly expressed in us to regulate development. This provides an evolutionary basis for neurodynamic networks to have retained these developmental characteristics, enabling entheogenic serotonin receptor agonists to alter the emotional dynamics of the networks of the ego attuned for organismic and kin survival to promote collective survival, experienced as union the with mind at large. It is also consistent with consciousness emerging at the level of the eucaryote cell.

The developmental paradigm outlined in fig 122 also underlines the fact that the entire network architecture of the brain is the result of a developmental social interaction between specific cell types of neural epithelial cells differentiating into glial and neuronal cell types, which then, in a coordinated sequence, undergo a dynamic state of

cell migration where differentiating cells use the glial scaffold to locate their cell bodies in the appropriate places in the cortical layers before sending out dendrites and axons to make contact with the cell types with which they will eventually form the functional brain's global network.

Cell migration to achieve this has to occur on multiple fronts. In **radial migration**, Neural stem cells proliferate in the ventricular zone lower in fig 122 (1, 2). The first postmitotic cells to migrate from the preplate become Cajal-Retzius cells and subplate neurons, migrating by somal translocation. The cells are bipolar and attach the leading edge of the process and the soma is then transported by nucleokinesis, via a microtubule "cage" around the nucleus elongating and contracting in association with the centrosome to guide the nucleus to its final destination. Radial fibres (radial glia) can translocate to the cortical plate and differentiate either into astrocytes or neurons. Somal translocation can occur at any time during development. Subsequent waves of neurons split the preplate by migrating along radial glial fibres to form the cortical plate. Each wave of migrating cells travel past their predecessors forming layers in an inside-out manner, meaning that the youngest neurons are the closest to the surface. It is estimated that glial guided migration represents 80-90% of migrating neurons. Most interneurons and Cajal-Retzius cells migrate **tangentially** through multiple modes of migration to reach their appropriate lateral location in the cortex. Many neurons migrating along the anterior-posterior axis of the body use existing axon tracts to migrate along in a process called **axophilic migration**. An example is GnRH- expressing neurons, which make a long journey from their birthplace in the nose, through the forebrain, and into the hypothalamus. **Neurophilic migration** involves the migration of neurons along an axon belonging to a different cell type. **Gliophilic migration** is the migration of glia along glial fibres.

The resulting picture is that the entire global network structure of the mature nervous system has arisen through the intelligent strategic activity of individual glial and neuronal cells responding to morphogenic, cell identifying and neurotransmitter clues. There is obviously a genetically based adaptive program in play to achieve this, but the resulting complexity is vastly higher than the complexity of the human genome, so it has to take place through individual cells responding intelligently to the cellular signals in their immediate environment. The conscious biological brain remains the most ecosystemically complex diverse "computational" system in the universe and the only one capable of subjective conscious awareness, recent studies of the mouse brain (Yao et al. 2023) and human synaptic proteome (van Oostrum et al. 2023) show vast diversity with no less than 5,300 types of neuron and neuroglia in the with 10^{15} synapses over 10^{10} very complex non-linear neurons with up to 10^5 different synapses involving multiple receptor types on each. This is general natural intelligence at the molecular level, at cosmological climax.

As the nervous system matures and active excitable network communication arises, edge of chaos excitability forms a dynamic inducer of network connectivity and synaptic adaption, working through the sensory systems from the outside in, with the retina, modulating the input nuclei such as the lateral and medial geniculate in the thalamus and finally the cortex. This means that the notion of the mature brain as simply a synaptic network where the cells are simple functional modules summing up synaptic inputs and encoding these inputs in an action potential firing rate are gross trivialisations of the neurons and glial cells, whose interactive intelligence has been responsible, not just for ongoing adaptive brain states, but the entire structure and function of the nervous system. There is no evolutionary sense in their regressing to a McCulloch-Pitts zombie state having intelligently generated the entire brain.

The idea of the brain as simply a biological neural network of summative synaptic units with thresholds and long term weighting adjustments is thus a highly incorrect simplification, while the idea of the brain as a social network of participating highly intelligent cells both causing the entire fabric and its collective activity in conscious mental states is

the correct one and the one that remains informative about all forms of adaption, learning and memory in which the human brain is involved. Likewise the idea that the neurons are just "cellular" automata while the networked brain somehow has emergent conscious from its network complexity is a Zeno's paradox fallacy. Nuclear functions, including genetic and epigenetic modification have been cited as a basis of long term memory whose basis lies in existing cellular memory processes (Miller et al. 2010, Yu et al. 2011, Bernstein 2022).

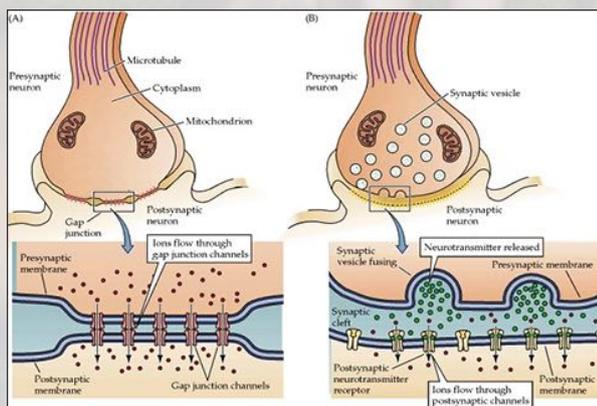

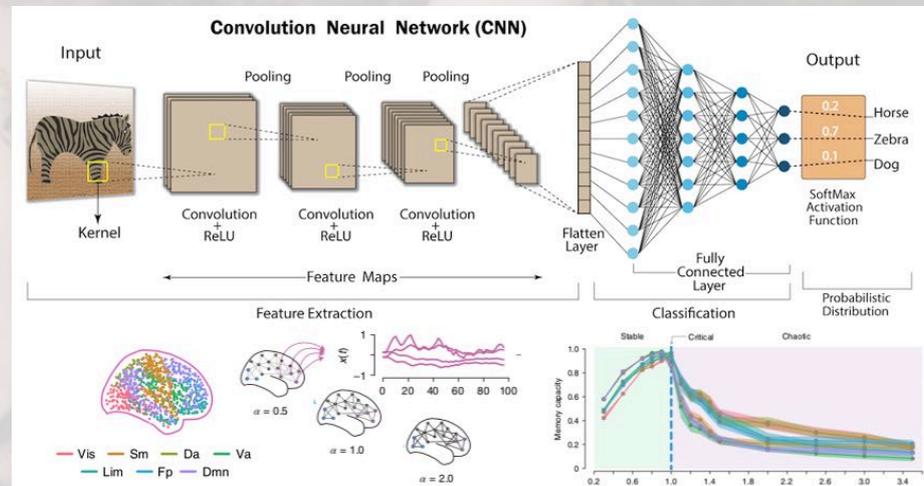

Fig 123: Electrical and biochemical synapses.

Critical to this is the fact that even the brains of humans consist of an intimately coupled society of intelligent amoeboid cells communicating via the same neurotransmitter molecules that single-celled eucaryotes use to engage social signalling to ensure the survival of the collective organism. While both ionotropic and metabotropic neuro-receptors and modulators, based on chemical neurotransmitters, form the principal interactive longitudinal network pathways, electrical synapses using gap junctions have also evolved in metazoa (Söhl et al. 2005, Purpura 2014, Martin et al. 2020). But these have not replaced the dependence on biochemical synapses, showing the latter have, throughout multicellular evolution remained essential to organismic survival. The brain has thus, even given the genetic where-with-all to do so, never evolved to become a purely electrochemical neural net that could be adequately modelled by artificial electrical neural net processes. Electrical synapses do have complementary roles to biochemical synapses, enabling fast resonant activity maintaining synchrony, especially in lateral connections, e.g. in the retina (Trenholm & Awatramani 2022), enabling volume transmission (diffusion through the extracellular space of neurotransmitters that reach remote target cells) and generating electrical fields that are capable of influencing the excitability of nearby neurons. Gap junctions can also pass smaller molecules such as ATP and second messengers, so they are not exclusively electro-chemical. They are also bi-directional, while biochemical synapses are unidirectional. Mixed function chemical and electrical synapses also occur.

The final aspect of this is that the process is not just cellular but is a dynamic fractal from the quantum level to the global brain state. It is operating using wave phase coherence in feedback between continuous and discrete signalling and it is operating at the edge of chaos (King 2014, Teuscher 2022), so its dynamical properties are in a state of self-organised criticality at the quantum level. It is thus in a state of sustained causal uncertainty.

There can be no comparison between the conscious mammalian brain and any externally designed artificial neural net, because the biological one is intelligently designed from the cell up, through the development process, rather than having an externally imposed serial structure, as in a convolutional neural networks, or even random neural nets approximating cerebral circuits, which lack the fractal functionality, thus making machines with subjectively conscious volition, improbable to untenable (Ricci, Cadéne & Serre 2021, Schaeffer, Khona & Fiete 2022, Feather et al. 2023). Artificial neural nets do not have the edge of chaos phase coherence sampling dynamics of the neurodynamic brain.

Fig 124: Upper a convolutional neural net is an externally designed serial causal chain where convolutions of the image are first formed and then a multilayer neural net is entrained on the data to produce a pattern discriminator. The neural nets are simple Hebbian nets connected in series. Lower: An experiment to measure net memory capacity in simple neural nets by iterative synaptic modification designed to have rough quasi-random connections modelled on brain neural networks, tested on active field overlap α (Suárez et al. 2021).

Deep and Dreaming Sleep Across the Animal Evolutionary Tree.

Human sleep runs in cycles descending into deep non-REM States characterised by deep slow waves and periodically rising with increasing frequency during the night to shorter phases of REM (paid eye movement) sleep, where the brain activity closely resembles the waking state but the body is largely paralysed. This is when the rich phases of dreaming occur.

A collection of theories of REM and non-REM sleep have attempted to associate dreaming phases with memory consolidation processes – through specific patterns of neuromodulatory activity and electric field potential oscillations, slow-wave sleep (SWS) and rapid eye movement (REM) sleep support system consolidation and synaptic consolidation, respectively. During deep sleep, slow oscillations, spindles and ripples - at minimum cholinergic activity - coordinate the re-activation and redistribution of hippocampus-dependent memories to neocortical sites, whereas during REM

sleep, local increases in plasticity-related immediate-early gene activity - at high cholinergic and theta activity — may favour the subsequent synaptic consolidation of memories in the cortex (Diekelmann & Born 2010, Stickgold & Walker 2007). Studies show that people perform better at memorisation tasks when they have had a good episode of REM sleep. The direction and amplitude of rapid eye movements during REM sleep disclose gaze shifts in the virtual world of REM sleep, thereby providing a window into the cognitive processes of the sleeping brain (Senzai & Scanziani 2022). Researchers studying mice have found a causal relationship between REM sleep and memory consolidation (Boyce et al. 2016). The memory enhancements of sleep also appear to be specifically targeted at memories the individual perceive to have future relevance. The mere expectancy that a memory will be used in a future test determines whether or not sleep significantly benefits consolidation of this memory. (Wilhelm, et al. 2011). However, although we often forget our dreams consistent with memory reprocessing taking place, if we are awakened immediately from REM sleep, or our sleep is disturbed, we can often remember complex dreams in their entirety, or even become aware enough to realise we are dreaming and enter a lucid dreaming state.

Deep non-REM sleep has also been associated with consolidation of synaptic connections. Sleep after motor learning promotes the formation of postsynaptic dendritic spines on a subset of branches of individual layer V pyramidal neurons. Such neurons activated during learning of a motor task are reactivated during subsequent non-rapid eye movement sleep, and disrupting this neuronal reactivation prevents branch-specific spine formation (Yang et al. 2014). More generally sleep appears to consolidate motor learning at the burst levels attained immediately after training (Nettersheim 2015). It has also been found that sleep re-calibrates homeostatic and associative synaptic plasticity, believed to be the neural basis for adaptive behaviour, in humans (Kuhn et al. 2016). It has been found that in young people sleep spindles remain in synch with large slow waves, which may enable the prefrontal cortex to encode memories being transferred from the hippocampus, leading to consolidation. In older people disruption of this synchrony appears to lead to loss of memory consolidation during sleep (Helfrich et al. 2017).

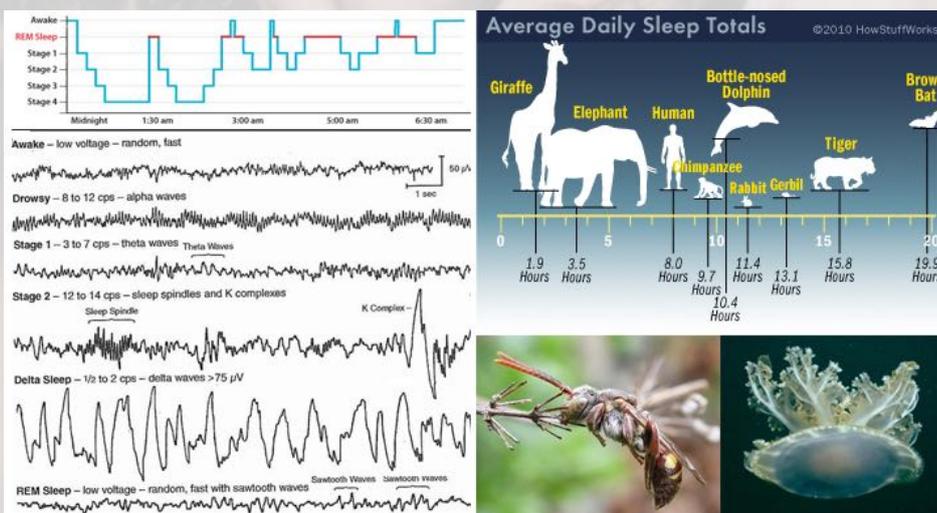

Fig 125: Left stages in the human sleep cycle. Top right: Variations in mammalian daily length of sleep. Lower right: Sleep like torpor in Panurginus and inverted Cnidarian.

There is wide variation in the sleep between mammal species. For example a giraffe only sleeps an average of 1.9 hours, both chimps and orangutans sleep longer than humans 9.67 and 9.11, while a tiger slumbers for 15.5 and an armadillo 20.4. As well as

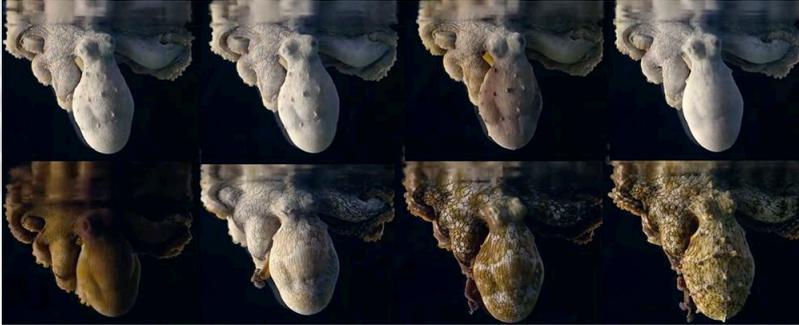

depending on metabolic rates, sleep periods, which extend to both the vertebrates and arthropods, can provide a protective role, keeping animals, which are either nocturnal or diurnal, out of the sight of predators during their inactive hours. The extent of the REM phase also varies widely between mammal species. Animals with big brains for their body size need a significantly higher percentage of REM sleep, supporting a role in intelligence and cognitive function (Lesku et al. 2008). Humans have atypically short sleep compared with closely related primates and pack an unexpectedly higher proportion of REM sleep within a shorter overall sleep duration, and do so by reducing NREM sleep, rather than increasing REM. (Nunn & Samson 2018). Notably cetaceans sleep a single cortex at a time, rather than the whole brain to enable swimming.

Fig 126: REM sleep in kittens, and baby jumping spiderlets.

Recent research has highlighted REM

phases of sleep running far down the evolutionary tree. They are noted in zebra fish (Leung et al. 2019). Jumping spiderlets have been filmed going through periods of quiescent sleep hanging on a thread, interspersed with short periods of eye movement and leg twitching characteristic of mammalian REM sleep (Rößler et al. (2022). Furthermore, cephalopods, including octopi and squids have been shown to likewise have periods of active sleep in which rapid changes in skin colouration appear to coincide with an active dreaming state (Iglesias et al. 2019, Medeiros et al. 2021) coinciding with a perceived series of encounters as shown in the figure. Jumping spiders have excellent camera eyes, unlike the compound eyes of insects.

This raises intriguing questions about the fundamental role of dreaming consciousness throughout the animal tree despite highly divergent brains of molluscs, arthropods and vertebrates, hinting at a universal form of consciousness in all animal life forms.

Fig 127: Changes in skin colouration in an octopus indicate a dream involving rising from the ocean floor (dark transition) and hunting and eating camouflage.

The Evolving Human Genotype: Developmental Evolution and Viral Symbiosis

To gain an empirical view of how these various evolutionary factors play out in practice, we now turn to examining in detail the evolutionary processes of replication and selection as they apply to our own species.

The double stranded human genome consists of some 3×10^9 base pairs, including only ~21,000 protein-coding genes making up around 1% of the genome. More than 80% of the human genome has some active biochemical activity. Although it is currently unknown whether all of this DNA contributes to cellular function, the majority can be transcribed into RNA. Nearly 20 percent of the genome is associated with DNase hypersensitivity or transcription factor binding, identifiable with regulatory regions, of which more than 4 million have been identified (Zhao 2012).

Many of these protein coding genes, including the nuclear core metabolic genes arising from the endosymbiotic α -proteobacteria that became our mitochondria, first evolved in the great archaean expansion 3.2 billion years ago (David & Alm 2010), so that the phenotypic evolution of higher organisms has become a regulatory symphony orchestrating the expression of these genes and later homeotic morphogenetic genes that arose with the first metaphyta in ever more evolved regulatory relationships, through natural and sexual selection based on animal survival and reproduction.

As Gerhart & Kirschner (2007) note:

Regulatory change acts on the repertoire of unchanging core processes to select subsets, which are then externally selected upon. The burden of creativity in evolution, down to minute details, does not rest on selection alone. Through its ancient repertoire of core processes, the current phenotype of the animal determines the kind, amount, and viability of phenotypic variation the animal can produce in response to regulatory change. Thanks to the nature of the processes, the range of possible anatomical and physiological variations is enormous, and many are likely nonlethal, in part simply because the processes have been providing "useful" function since pre-Cambrian times. Phenotypic plasticities, both those evokable by environmental change and those developmental adaptabilities not evocable, are rich sources and favored paths of variation requiring little regulatory change.

This brings us to the selfish gene part, which invokes an extraordinary symbiotic evolutionary story over very long time scales. Around 46% of the human genome consists of transposable genetic elements (TEs) and endogenous retroviruses, which can take on a selfish life of their own. The evolutionary distribution of these elements in the human genome is illustrated in fig 100. TEs can be separated into two major classes: DNA transposons and retrotransposons. DNA transposons, making up ~3% of the human genome, can excise themselves from the genome, move as DNA and paste themselves into new genomic sites. Although they are currently not mobilising in the human genome, they were active during early primate evolution, until ~37 million years ago. Retrotransposons duplicate via transcribed RNA intermediates that are reverse-transcribed and inserted at new genomic locations. They consist of two groups, with and without long terminal repeats (LTRs). Human LTR elements are endogenous retroviruses which

account for ~8% of the genome, most inserted in the human genome >25 My ago, and their activity is presently very limited in humans. Nevertheless, HERV-derived transcripts and proteins have been detected in healthy and diseased human tissues, and HERV-K, the youngest, most conserved family, is able to form virus-like particles (Bannert & Kurth 2004). By contrast, the vast majority of human TEs result from the present and past activity of non-LTR retrotransposons, typified by LINE-1 (or L1), Alu and SVA elements, that collectively account for about one third of the human genome. These are the only TEs unequivocally shown to be currently active in humans, as demonstrated by de novo insertions causing genetic disorders (Cordaux & Batzer 2009), including loss of the tail in apes (Xia et al. 2024).

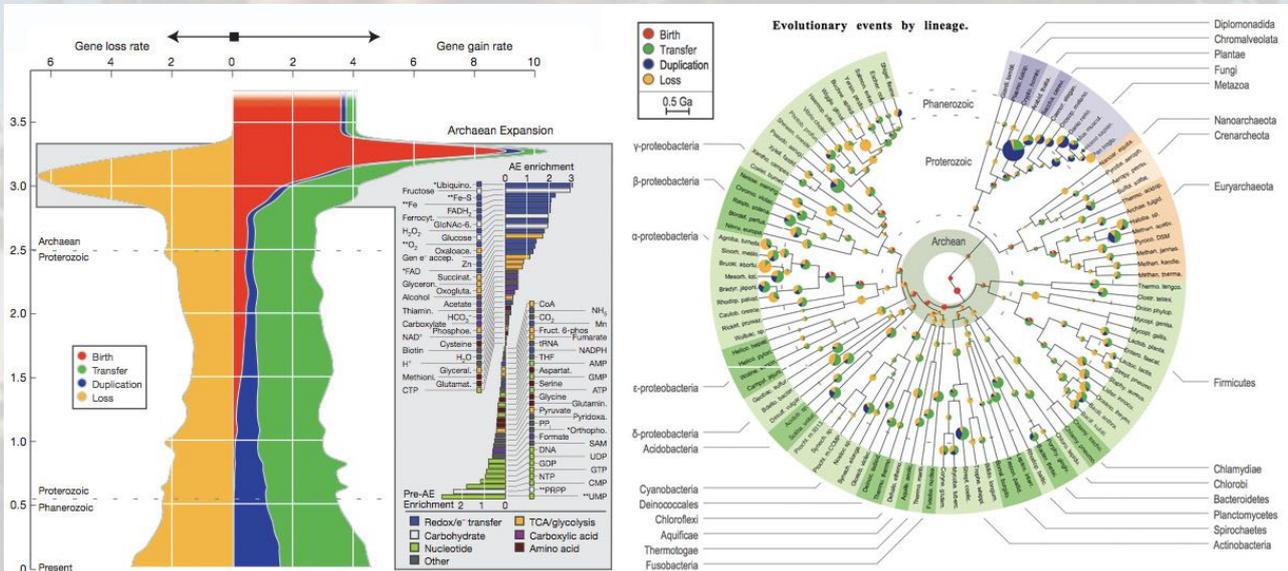

Fig 128: Tree diagram of the birth, transfer, duplication and loss of key genes in the redox and electron transport pathways, in a founding burst of gene evolution between 3.3 and 2.7 billion years ago (David & Alm 2010).

There are >500,000 L1 copies in the human genome, resulting from their continued mobilisation for the past 150 My. L1 elements constitute ~17% of the human genome. There are >1 million Alu copies in the human genome, resulting from their continued activity throughout the past ~65 My. Alu elements have no coding capacity and are, therefore, non-autonomous TEs – “a parasite’s parasite”. Instead, they borrow the processes encoded by L1 elements. There are ~3,000 SVA copies in the human genome, resulting from continued activity throughout the ~25 My of hominid evolution. SVA elements are non-autonomous TEs mobilised by the L1 machinery. Before the autonomous L1 element and its Alu parasite expansions, the genome experienced the autonomous L2 element and its MIR parasite. The current rate of Alu and L1 retrotransposition has been estimated as one insertion every 20-200 births in humans.

We now investigate the ecology, parasitism and symbiotic implications of transposable elements. TEs are not randomly distributed. The genome may be viewed as an ecosystem inhabited by diverse communities of TEs, which seek to propagate and multiply through parasitism, cooperation, and competition. Many elements have evolved mechanisms to target specific loci where their insertions are less detrimental to the host but favourable for their propagation. The success and diversity of TEs in a genome are shaped both by properties intrinsic to the elements as well as evolutionary forces acting at the level of the host species (Bourque et al. 2018 and ensuing paragraphs).

To survive in evolution, TE expression needs to strike a balance – sufficient to promote amplification, but not so vigorous as to lead to a fitness disadvantage for the host offsetting the benefit to the TE. TE-encoded enzymes are naturally suboptimal for transposition and why some TEs have evolved self-regulatory mechanisms controlling their own copy numbers. A variety of host factors are also employed to control TE expression, which includes a variety of small RNA, chromatin, and DNA modification pathways, and sequence-specific repressors such as KRAB zinc-finger proteins. However, many of these silencing mechanisms must be at least partially released to permit developmental regulation of host gene expression programs, particularly during early embryonic development. For example, genome-wide loss of DNA methylation is necessary to reset imprinted genes in primordial germ cells. This affords TEs an opportunity, as reduced DNA methylation often promotes TE expression. There is also a large body of evidence supporting the idea that horizontal transposon transfer is a common phenomenon that affects virtually every major type of TE and all branches of the tree of life, in addition to endogenous vertical transfer in organismic reproduction.

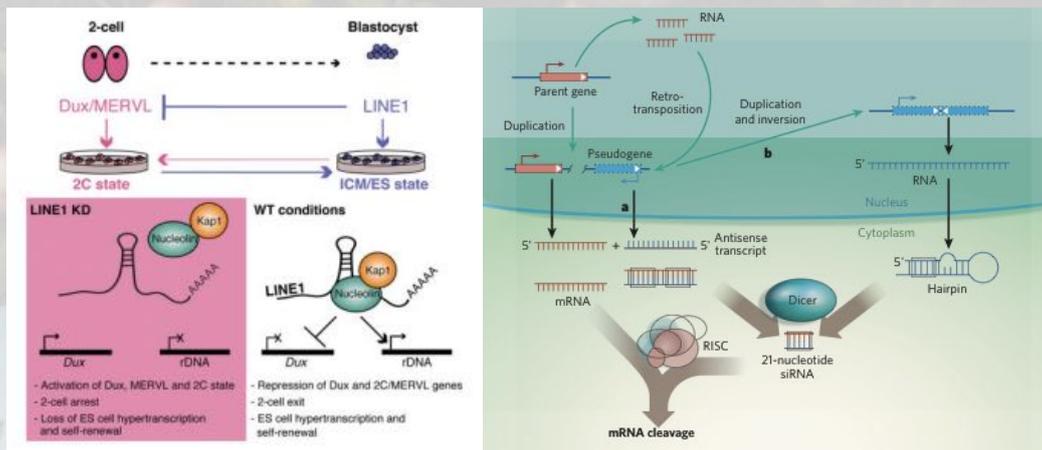

Fig 129: (Left) LINE-1 RNA mediates binding of Nucleolin and Kap1 to rDNA, promoting rRNA synthesis and ESC self-renewal. (Right) Pseudogene-mediated production of endogenous small interfering RNAs (endo-siRNAs). Pseudogenes can arise through the copying of a parent gene (by duplication or by retrotransposition). (a) An antisense transcript of the pseudogene and an mRNA transcript of its parent gene can then form a double-stranded RNA. (b) Pseudogenic endo-siRNAs can also arise through copying of the parent gene as in a and then nearby duplication and inversion of this copy. The subsequent transcription of both copies results in a long RNA, which folds into a hairpin, as one half of it is complementary to its other half. In both a and b, the double-stranded RNA is cut by Dicer into 21-nucleotide endo-siRNAs, which are guided by the RISC complex to interact with, and degrade, the parent gene's remaining mRNA transcripts. The mRNA from genes is in red and that from pseudogenes is in blue. Green arrows indicate DNA rearrangements (Sasidharan R, Gerstein M 2008 *Protein fossils live on as RNA* Nature 453/5 729-32).

TEs are an extensive source of mutations and genetic polymorphisms. More than 99.9% of the ~500,000 L1 copies are no longer mobile due to various forms of mutations and truncations. It is estimated that each person carries a set of ~100 active L1 elements, mostly young insertions still segregating within the human population. TEs are associated with genome rearrangements and unique chromosome features. Transposition represents a potent mechanism of genome expansion that over time is counteracted by the removal of DNA via deletion. The rate at which TEs transpose, which is in part under host control, is an important driver of genome evolution.

To replicate down the germ line L1 elements are preferentially expressed in both germ-line tissues and spermatogenic mice (Branciforte and Martin 1994, Trelogan and Martin 1995). L1 RNA transcripts are generated in several stages of spermatogenesis including leptotene, and in the primary oocytes of females poised at prophase 1 and predominantly become expressed after fertilisation in embryogenesis (Lyon et al. 2010). Most insertions are in somatic cells leading to somatic mosaicism and only a small subset in germ line cells. This could enable somatic stress to have a potential effect on translocation in the germ-line which might enable forms of genetic adaption in long-lived species such as humans (King 1985, 1992). Conversely the SRY-group male determining gene SOX has been found to regulate LINE retrotransposition (Tchénio et. al. 2000).

L1 is highly expressed during early development and plays essential roles in mouse embryonic stem cells and pre-implantation embryos. RNA transcribed from LINE1 elements acts as a nuclear scaffold that recruits Nucleolin and Kap1/Trim28 to repress Dux, the master activator of a transcriptional program specific to the 2-cell embryo, directing gene expression programs essential for embryonic stem cell self-renewal, pre-implantation embryo development, and exit from the 2-cell stage to the blastocyst (Percharde M et al. 2018).

L1 elements have also been found to replicate in neural progenitor cells in both the mouse and human and copy numbers have been found to increase in the hippocampus, and in several regions of adult human brains, when compared to the copy number of endogenous L1s in heart or liver genomic DNAs from the same donor. The authors comment that these data suggest that de novo L1 retrotransposition events may occur in the human brain and, in principle, have the potential to contribute to individual somatic mosaicism (Coufal et. al. 2009). L1s were found to be able to mobilise in mammalian neural progenitor cells (NPCs) isolated from adult rat hippocampus (Muotri et al 2005). During development, neurons migrate from the proliferative zones as hippocampus and subventricular zone toward the surface of the brain to form six distinct histological layers and establish new neuronal networks. Thus, L1-associated mutations occurring in progenitor cells could potentially change the cellular phenotypes in the nascent neurons. L1 retrotransposition was found in the striatum, cortex, hypothalamus, hilus, cerebellum, ventricles, amygdala, and hippocampus. Estimates from human hippocampus, were respectively 13.7 and 6.5 somatic L1 insertions per neuron and glia, respectively. More recently the L1 insertion rate in both neurons and glia from

hippocampus and frontal cortex of three healthy individuals was 0.58–1 events per cell. What seems to be certainly clear is that neuronal cells are more permissive for L1 retrotransposition than other cell types in the human body (Macia & Muotri 2017).

Although L1 elements do not have viral infectivity, lacking the envelope genes of retroviruses, there are recorded cases of horizontal gene transfer of L1 elements between species (Ivancevic et al. 2018). The line related bovine B element which also helps replicate a population of alu-like elements, has made multiple interspecies transfers from predators (snakes) to their prey (frogs) through a variety of parasites (Adelson et al. 2009, Kambayashi et al. 2022).

The use of next generation sequencing has provided additional insights into the L1 role in the mammalian brain, which demonstrate that is indeed made of a mosaic of genomes. Mice in running wheels had threefold more L1 retrotransposition than mice in sedentary environments. In human, the expression of L1 retroelements has been linked to several psychopathological conditions such as post-traumatic stress disorder and major depressive disorder (MDD). MECP2, a protein involved in global DNA methylation, along with the transcriptional factors Sox2 and HDAC1, is known to form a repressor complex on the L1 promoter region, controlling L1 neuronal transcription and thus retrotransposition. Mutation of MECP2 in humans causes Rett syndrome (RTT), a progressive neurological disorder being considered part of the autism spectrum disorders (ASD). Terry & Devine (2020) note aberrantly high levels of L1 expression and retrotransposition in Human Neurological Disorders. The activated L1s act as alternative promoters for many protein-coding genes involved in neuronal functions, revealing a hominoid-specific L1-based transcriptional network controlled by DNA methylation that influences neuronal protein-coding genes (Jönsson M et al. 2019).

Ivancevic et al. (2016) have traced the evolutionary tree of L1 back to the founding eucaryotes as L1 elements occur in both plants and animal phyla spanning vertebrates, arthropods, and molluscs such as octopi where L1 transposition has specifically been associated with high-intelligence where transcription and translation measured for one of these elements resulted in specific signals in neurons belonging to areas associated with behavioural plasticity (Petrosino et al. 2022). L1, along with DNA transposons and LTR retroelements are ubiquitous across the arthropod kingdom (Petersen et al. 2019).

Similarly inactive L1 elements have been found to be 'boosters' of one X chromosome in collapse of one of the two X chromosomes in somatic lines that happens in female embryogenesis (Lyon 2000). A subset of young LINE-1 elements, however, is expressed during X inactivation, rather than being silenced. Such LINE expression requires the specific heterochromatic state induced by Xist. These L1s often lie within escape-prone regions of the X chromosome, but close to genes that are subject to X inactivation, and are associated with putative endo-siRNAs small interfering RNAs that silence transposable elements. L1s may thus facilitate X inactivation at different levels (Chow et al. 2010).

A number of key coding and non-coding RNAs are derived from TEs. Although usually detrimental, there is growing evidence that TE insertions can provide raw material for the emergence of protein-coding genes and non-coding RNAs, which can take on important and, in some cases essential, cellular function. A spectacular example of deeply conserved TE-derived genes are Rag1 and Rag2, that catalyse V(D)J somatic recombination in the vertebrate immune system. Both genes, and probably the DNA signals they recognise, were derived from an ancestral DNA transposon around 500 million years ago.

One of the most intriguing examples of TE domestication is the repeated, independent capture of ERV env genes, termed syncytins, which are involved in placentation by facilitating cell–cell fusion and syncytiotrophoblast formation. These multinucleated cells originate from fetal trophoblasts and constitute the boundary layer between maternal and fetal tissue. The major functions of this layer include maternal–fetal exchange and the maintenance of immunologic tolerance toward the developing fetus (Bannert & Kurth 2004). Notably, one or more such syncytin genes have been found in virtually every placental mammalian lineage where they have been sought, as well as some placental lizards, strongly suggesting that ERVs have played essential roles in the evolution and extreme phenotypic variability of the mammalian placenta (Lavialle et al. 2013, Cornelis G et al. (2017). Another is RNA expression of retroviral RNLTR12-int (Retro-myelin) crucial for myelination, by binding to SOX10 to regulate myelin basic protein expression. It occurs in all jawed vertebrates through multiple convergent evolution events after initial speciation (Ghosh et al. 2024).

Another example of a viral-sourced activity re-purposed for host cell function is provided by the neuronal Arc gene, which arose from the gag gene from a LTR retrotransposon domesticated in the common ancestor of tetrapod vertebrates. Genetic and biochemical studies of murine Arc show that it is involved in memory and synaptic plasticity

and has preserved most of the ancestral activities of Gag, including the packaging and intercellular trafficking of its own RNA (Pastuzyn et al. 2018, Nikolaienko et al. 2018).

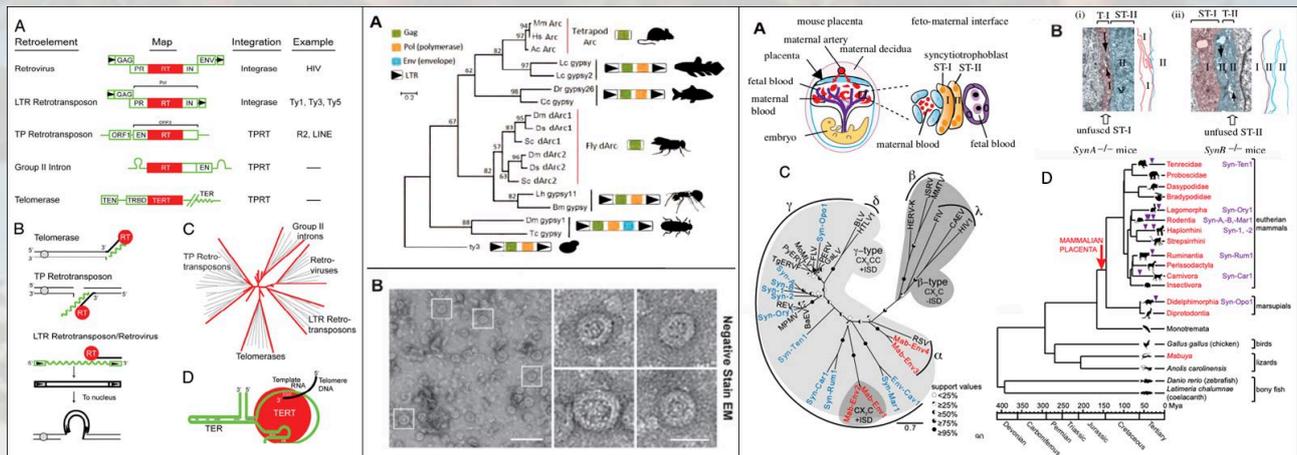

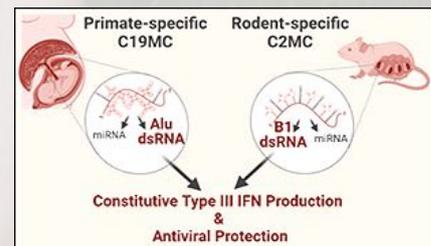

Fig 130: Left: Telomerase containing an ancient relative of TE reverse transcriptase shows a deep evolutionary link with all retroelements. Centre: The arc gene involved in retrovirus like particles in neural plasticity arose independently from gypsy elements in both mammals and *Drosophila*. Right: Syncytin essential for the placental membrane has been incorporated across mammals, some marsupials and a placental lizard from retroviral Env genes.

Unlike prokaryotes, eucaryote protein-coding genes are interspersed with non-coding introns between the exons that constitute functional pieces of the coded protein which have to be excised before translation. Introns allow for alternative splicing to produce different proteins and enable evolution to be modular and to recombine exons into new proteins, so they are a crucial part of eukaryotic genomes, but their origins are poorly understood. Some lineages exhibit large-scale gains in introns extremely rapidly. This is consistent with a type of element, introners, that create copies of themselves that insert into many genes across the genome, leaving behind introns, which can be removed by spliceosomes. These appear to have evolved convergently from many distinct genetic elements, most are consistent with DNA-based transposable elements, and they are disproportionately common in the genomes of aquatic organisms where horizontal genetic transfer is more common (Roy et al. 2020, 2023, Gozashti et al. 2022).

TEs can donate their own genes to the host, and they can also add exons and rearrange and duplicate existing host genes. In humans, intronic Alu elements are particularly prone to be captured as alternative exons through cryptic splice sites residing within their sequences. L1 and SVA (SINE/VNTR/Alu) elements also contribute to exon shuffling through transduction events of adjacent host sequences during their mobilisation. In both mice and humans, the placenta utilises SINE elements (Alu and B1) to form ds-RNA to modulate the immune system in pregnancy to induce type III interferon to avoid viral disease while not inducing rejection of the embryo(s). By pretending it's under viral attack, it keeps the immune system running at a gentle, steady pace to protect the enclosed foetus from viruses that slip past the mother's immune defences (Wickramage et al. 2023). The reverse transcriptase activity of retroelements is also responsible for the trans-duplication of cellular mRNAs to create 'processed' retrogenes in a wide range of organisms. The L1 enzymatic machinery is thought to be involved in the generation of tens of thousands of retrogene copies in mammalian genomes, many of which remain transcribed and some of which have acquired new cellular functions. This is a process still actively shaping our genomes; it has been estimated that 1 in every 6000 humans carries a novel retrogene insertion.

TEs also make substantial contributions to non-protein coding functions of the cell. They are major components of thousands of long non-coding RNAs in human and mouse genomes, often transcriptionally driven by retroviral LTRs. Some of these TE-driven lncRNAs appear to play important roles in the maintenance of stem cell pluripotency and other developmental processes. Many studies have demonstrated that TE sequences embedded within lncRNAs and mRNAs can directly modulate RNA stability, processing, or localisation with important regulatory consequences. Furthermore, TE-derived microRNAs and other small RNAs processed from TEs can also adopt regulatory roles serving host cell functions. The myriad of mechanisms by which TEs contribute to coding and non-coding RNAs illustrate the multi-faceted interactions between these elements and their host.

TEs contribute cis-regulatory DNA elements and modify transcriptional networks. Cis-regulatory networks coordinate the transcription of multiple genes that function in concert to orchestrate entire pathways and complex biological processes. There is now mounting evidence that TEs have been a rich source of material for the modulation of eukaryotic gene expression. TEs can disperse vast amounts of promoters and enhancers transcription factor binding sites, insulator sequences, and repressive elements. As TE families typically populate a genome as a multitude of related copies, it has long been postulated that they have the potential to donate the same cis-regulatory module to ‘wire’ batteries of genes dispersed throughout the genome. An increasing number of studies support this model and suggest that TEs have provided the building blocks for the assembly and remodelling of cis-regulatory networks during evolution, including pathways underlying processes as diverse as pregnancy, stem cell pluripotency, neocortex development and innate immunity.

We now turn to the overall mutational load of all these processes. Xue Y et al. (2009) set an even lower limit examining the Y chromosome of 3.0×10^{-8} mutations/nucleotide/generation, giving 90 per haploid genome. Harris & Pritchard (2017) note that due to the combined action error correcting genes, mutation rates are extremely low in humans – about one point mutation per 100 MB or about 60 genome-wide per generation. Given only 1% coding this would imply only around 0.6 coding mutations per generation consistent with the raw assumption of around 0.5.

Feusier J et al. (2019) have provided the following retrotransposition rate estimates for Alu elements, one in 40 births, is roughly half the rate estimated using phylogenetic analyses of one in 20, a difference in magnitude similar to that observed for single-nucleotide variants. The L1 retrotransposition rate is one in 63 births and is within range of previous estimates (1:20–1:200 births). The SVA retrotransposition rate, one in 63 births. While these are more disruptive or retrogene TE insertions, the rates of both are broadly consistent with a viable mutational load under integrative mutational change accompanied by sexual recombination.

This picture has shown us a comprehensive view of how the organismic human genome succeeds in maintaining a balance with its “selfish” TEs, in which feedback between TE transposition, host repression and a wide array of symbiotic evolutionary manifestations have resulted in a co-evolutionary scenario in which the TEs have become (or have always been) essential complements of the host nuclear genome, providing us with the capacity for passing the two cell embryo stage, enabling placental development, contributing to neural plasticity and learning and the very basis of our antibody immunity.

The Evolving Human Phenotype 1: Sexual Evolution, the Heritage of Sexual Love and Patriarchal Dominion

In “The Woman that never Evolved”, Sarah Hrdy (1981) conveyed a previously unrecognised view of the primate female in the span of her transition to humanity: *we are introduced to our nearest female relatives: competitive, independent, sexually assertive primates who have every bit as much at stake in the evolutionary game as their male counterparts do. These females compete among themselves for rank and resources, but will bond together for mutual defense. They risk their lives to protect their young, yet consort with the very male who murdered their offspring when successful reproduction depends upon it. They tolerate other breeding females if food is plentiful, but chase them away when monogamy is the optimal strategy. When “promiscuity” is an advantage, female primates—like their human cousins—exhibit a sexual appetite that ensures a range of breeding partners. From case after case we are led to the conclusion that the sexually passive, noncompetitive, all-nurturing woman of prevailing myth never could have evolved within the primate order.*

Human evolution and cultural emergence has thus been marked by a strong influence of female reproductive choice, amid mutual mate choice, accompanying a long slowly developing childhood. This is consistent with our closest sister species, chimps and bonobos having a mix of female exogamy and male clan dominance in chimps, and powerful alpha females in bonobos, where sexual evolution of the clitoris has led to frequent female-female socio-sexual bonding (Fielder & King 2004 A). The eschewing of overt estrus in favour of menstruation in humans, combined with a degree of lunar and menstrual synchrony also leads to female reproductive choice operating strategically to offset male reproductive domination and threats of male infanticide.

Indeed human sexual evolution, perpetual socio-sexual receptivity accompanied by ecstatic female arousal, the foregoing⁴⁹ of overt oestrus in favour of menstruation, the need for human males to demonstrate genuine indicators

⁴⁹ It has been claimed that concealed estrus is not an evolved trait but an underlying primate condition and that overt estrus is an evolved trait due to sexual and social selection e.g. in chimps and bonobos (Laland & Brown 2002 13), as the majority of primate species, including most apes, do not reveal their time of ovulation.

of genetic fitness, both in a large penis lacking the penile bone of the great apes, and in hunting and social prowess, consistent with XY sex chromosome inheritance, complemented by lunar phasing and menstrual synchrony, attest to an evolutionary emergence of *Homo sapiens* strongly influenced by female reproductive choice (Fielder & King 2004).

Evidence for such archaic patterns is evident in the practices of founding human cultures, from 19th century accounts of ‘Hottentot’ women refusing sex unless meat is provided, through the Hadza to the Sandawe “twerking” rites by the light of the full moon (King & Fielder 2004 B), sometimes referred to as the “sex strike” (Knight 1991, Power & Watts 1996, King & Fielder 2004). Intense female clitoral orgasm, perpetual sexual receptiveness outside menstruation, the growth of female fatty breasts and neotinous features indicating fecundity and youthfulness and the loss of penis spines and bones, with growth of a large erectile penis in males, also attests to mutual sexual selection in humans enhancing both female sexual attractiveness and males having to give a genuine indicator of genetic fitness during sex.

Fig 131: Above Left: Chimp, bonobo and human penises compared. Both chimp and bonobo penises have penis bones and neuro-sensitive penile spines (one shown inset top left) with a very short copulatory period. The human penis is notably larger and testes smaller than chimps. Below Left: Bonobo and human clitoris. Bonobos have a large clitoris enabling female-female erotic contact but like chimps have an overt estrus (below centre). The human clitoris is smaller but highly sensitive with more nerve endings than the human penis. Centre and Right: Human pregnancy is a very significant risk and investment to the human female, involving risks of giving birth to a large head, travail vulnerability in late pregnancy, followed by years of breast feeding and early child rearing of a dependent infant. Male and female reproductive strategies are thus examples of sexually antagonistic co-evolution (Fielder & King 2004 D) in which males try to avoid paternity uncertainty by controlling female sexual choice leading to the sex wars and patriarchally driven sexual dominance. Female reproductive choice is thus essential to human evolution to counterbalance this effect. Centre: Infrared imaging of female sexual arousal is accompanied by blood flow to the labia and clitoris just as it is to the penis. This is central to the nature of human courtship and bonding between the sexes.

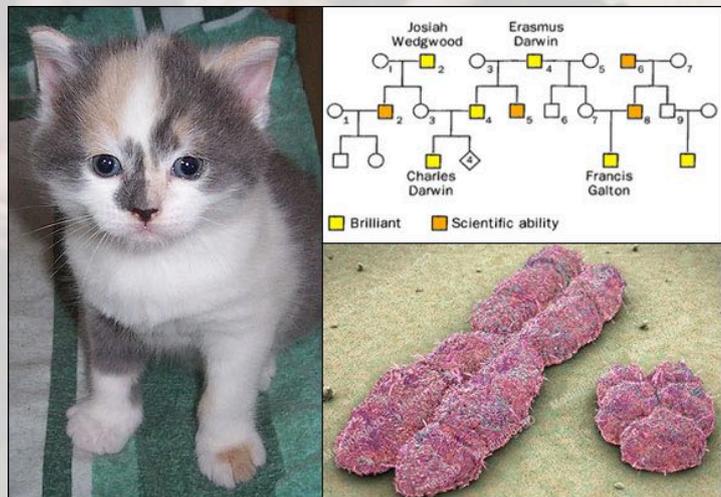

The emergence of super-intelligence in humans has also been associated with the “mating mind” (Miller 2000), in which men display their genetic prowess in hunting and their social skills in music, story-telling and social humour, while the women make astute social choices of who to get pregnant with, given a mix of good genes and resourcing required to bring up a human infant. Machiavellian social intelligence for strategic bluffing, is also evident in intelligent species, from capuchins to humans. Female sexual selection is consistent with XY sex chromosome inheritance, where the large X chromosome is unique in males but chimeric in females due to double X being toxic, except in the germ line (Turner 1996). This provides a context for males to demonstrate intellectual and social prowess due to their unique X whose genes may also serve reproductive choice in females. The X chromosome contains multiple genes linked to brain function and development, some of which are rapidly evolving, giving support to this idea.

My joint work with Christine (Fielder & King 2004) “Sexual Paradox: Complementarity, Reproductive Conflict and Human Emergence” set out the thesis that the emergence of human culture and super-intelligence arose from a reproductive prisoners’ dilemma of sexual selection game theory where neither sex had the upper hand in terms of their own highly asymmetric reproductive strategies, causing a peacock’s tail Red Queen race of mutual sexual selection for culture and intelligence, centrally mediated by astute female reproductive choice, in a context of mutual mate choice to enhance family stability. Because of the very high costs to mammal females due to having to invest in live birth, the female reproductive strategy is highly skewed towards careful parenting investment. By contrast mammalian male strategies are strongly skewed to fertilising as many females as possible. Hence only 3% of mammalian species are socially monogamous, although not genetically so, due to covert ‘cheating’ by both sexes. Humans are at an extreme for mammals, because of the high risks of delivering a large-headed baby, often as a single offspring, long periods of lactation and child care in a slowly-growing infant, requiring increasing cultural education put

these asymmetries at an extreme, leading to sexually-antagonistic co-evolution, manifest in existential conflicts of personal interest. This then becomes the process of sexual selection that is fixing the intellectual benefits of the emergence of language and culture we will see in the next section. It is a view confluent with evolutionary psychology, which we support, as giving expression to evolutionary sexual selection conducive both to human emergence and intelligence, and also to strongly pro-social influences of love consistent with long-term emergent stability.

This is partly underpinned by some beautiful aspects of mammalian sexual chromosome evolution. Mammals have an ingenious sexual genetic scheme to align sexual selection with the effects of the honest egg and the cheating sperm. The female XX and male XY means that the male is haploid X and the female diploid XX. The haploid state provides for maximal selective advantage, because there is just one 'pure' copy of each gene on this entire chromosome, not two interacting copies. When the female embryo begins to divide about the 10 to 20 cell stage, in each somatic cell i.e. apart from the germ-line sex cells, one or other X randomly collapses. So a female brain is single X, like the male, but with a difference - it is a mosaic of cells of two genetic X-identities, those of her father and mother, as in the picture of the tortoise-shelled cat. The male by contrast is endowed with one pure maternal X-dose. When he is good he is very very good - but when he is bad he is singularly retarded. There are at least 8 forms of X-linked male mental retardation because the X chromosome, the hemizygous 'haploid' X is carrying several key genes for brain development at the spearhead of human evolution (Turner 1996).

Fig 132: (Left) X-linked tortoise-shell gene variation demonstrates X-mosacism in a female cat on a scale where the brain would also be chimeaic. The confinement of this phenomenon to female felines combined with an elusive contracted genetic element in female somatic cells, the Baar body, was the trigger for Mary Lyon (2000), the discoverer of mosaic X-inactivation to make the discovery (Jegalian and Lahn 2001). (Top right) Darwin Family tree (Turner 1996). His grandfather was the founder of Wedgwood Pottery and his cousin, Galton, was a prolific writer and the founder of the Eugenic movement. The pedigree shown in the figure was said, at the beginning of the century, to indicate that genius is a Y-linked dominant, but it could equally well be explained by X linkage. Charles Darwin received Joshua Wedgwood's X chromosome and therefore his intelligence through his mother (11-3), and Erasmus Darwin's brilliance having reappeared in Francis Galton via his mother (11-7), rather than his father. Mary Howard (1-3), was also related to the Galtons. (lower right) Human X and Y chromosomes.

There are 221 known human genetic defects that can cause mental impairment, some 10% of which reside on the X chromosome, even though it carries less than 4% of known human genes and the complete sequence of the X chromosome (Ross et al. 2005), confirms that an unusually large number of its genes code for proteins important to brain function. Estimates of the increased likelihood of a deleterious mental impairment gene being on the X-chromosome range from 1.9 times through 4.3 times (Inlow & Restifo 2004) to 7.2 times (Zechner et al. 2001) giving it a pivotal role in the evolution of human intelligence. Researchers have also found that in some traits linked to intelligence, such as verbal skills and good social behaviour, male twins were more alike than female twins indicating X-linked genes in which the females are chimeric (Loatet et al. 2004).

In our species, where intelligence and social skills are central to success, genes on the X chromosome seem to have evolved rapidly to provide us with the necessary brain power (Check 2005). An explanation goes as follows. As the X and Y diverged from a common autosome pair they each began to accumulate autosomal genes. Ultimately the X and Y diverged to the point where most X genes cannot recombine with Y and become recombined only in female oogenesis. This makes the X one of the most stable in the mammalian genome, for two reasons. Firstly because the genes are expressed in almost exclusively haploid form in males, who have lost the corresponding Y genes, they need to be more strongly conserved according to Muller's ratchet theory. Secondly, mutation rates are much lower in females who produce a relatively small number of primordial eggs early in embryogenesis, as opposed to males, who produce vast numbers of sperm throughout life.

The stability and inheritance of the X may have paradoxically exposed X genes to more intense pressure to evolve. As genes became transferred between chromosomes, those involving intelligence that became transferred to the X

become exposed to acute sexual selection by females because in males, the X chromosome genes get a chance to shine, or to fail miserably, each time they pass through the male line. Because a male carries only one copy, any new mutations are revealed in all their glory.

Many of the genes on the X chromosome associated with human brain function seem to have distant relatives with different functions in other vertebrates, such as chickens and fish (Kohn et al. 2004). So in boosting our cognitive abilities, the X chromosome seems to have co-opted a diverse range of existing genes, rather than evolving a new set of genetic sequences for the purpose, posing a paradox of conservatism amid rapid change. In some instances, geneticists have pinpointed genes on the X chromosome that still seem to be in the process of adopting new roles in the brain. For instance, a gene called JARID1C seems to be evolving from a similar gene called JARID1D, which is found on the Y chromosome. If men inherit a damaged version of the JARID1C gene on their single X chromosome, they develop mental disabilities. The fact that the healthy Y chromosome version cannot compensate for its defective cousin hints that JARID1C is becoming more crucial to the brain as it evolves (Jensen et al. 2005).

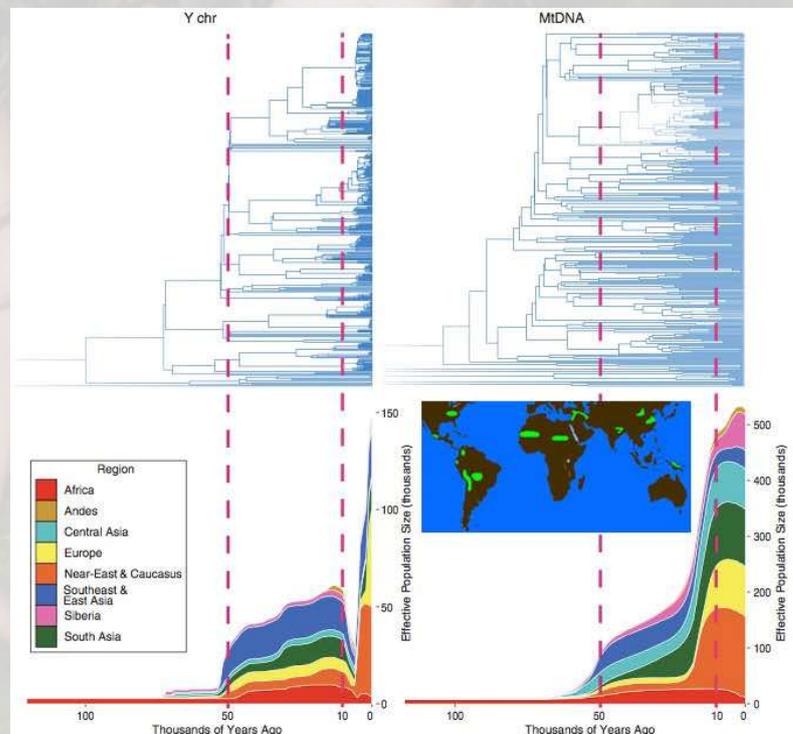

When the occasional man gets the pure benefit of a fortuitous X complementing his other good brain genes on the diploid chromosomes he may thus become a genius. The irony is that the male never can transmit this heritage to his sons. It is always the maternal X that goes to the son, because to be a son he must have got the paternal Y. Females are thus the progenitors of male prodigies, but the prodigies are doomed ducks. This is the sacrificial saga of the sex gene. The only hope for a male genius is to have daughters! By contrast, females can fortuitously give direct birth to male geniuses. This doesn't mean only males display creative genius. Neither does it deny the capacity of culture and education to mediate natural differences.

A revolutionary idea is that female genes encouraging female sexual selection for intelligence are strongly linked to genes for high intelligence selected for in the male. Early in human evolution, researchers suggest (Zechner et al. 2001), females developed a preference for intelligent males. According to the theory, the genes for super-intelligence and for the preference of intelligent males were closely linked, and so were inherited together. And because superior intelligence also aided survival, the process wasn't kept in check by natural selection — unlike other sexually selected characteristics such as the peacock's tail, which makes its bearers more vulnerable to predators. These X-linked genes then ran away together without any limitation by natural selection, because of the adaptive advantage of intelligence.

Fig 133: A human reproductive bottleneck in Y-chromosome diversity began about 10,000 years ago and continued for several millennia (Karmin et al. 2015). Inset shows 11 independent areas of primal agriculture discovered.

Laland's treatment of sexual selection is a glaring omission in terms of its pivotal role, all the more anomalous, given Darwin's own founding (1871) title on human emergence — "The Descent of Man, and Selection in Relation to Sex". When Laland does briefly touch on sexual selection in passing, it is only a brief reference with no implications articulated either for our emergence as a super-intelligent species, or for the effects of our epoch of 'civilised' culture for better or worse:

Even if human mating preferences are learned, socially transmitted, and culture specific, sexual selection will still result. Indeed, culturally generated sexual selection was found to be faster and more potent than its gene-based counterpart. ... experimental data shows that humans copy the mate choice decisions of others, which can lead to the social transmission of preferences for particular characteristics in the opposite sex. ... Given the pervasiveness of cultural influences on human mating preferences, social transmission may exert a powerful influence on the selection of secondary sexual characteristics and other physical and personality traits.

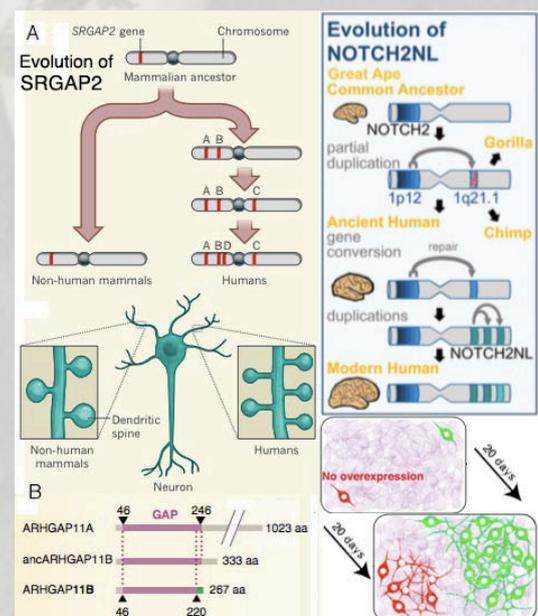

The Evolving Human Phenotype 2: Past and Future Evolution of the Brain and Human Intelligence

There is clear evidence for increasing brain size and intelligence, as primate evolution has proceeded from monkeys to apes, and finally humans. Genetic studies have found a number of intriguing improvements in neuronal brain structure in the evolution of *Homo sapiens* from higher apes. An outstanding example has been the *FoxP2* transcription factor gene (Enard et al. 2002), whose mutations can give rise to severe selective language impairment and appears to be associated with fine motor coordination of the larynx. Mutations in this gene are rare, but there has been a double mutation in this gene and the paucity of 'silent' neutral mutations which don't change the protein suggested it was a very recent change, later than 200,000 years ago, which has swept through the population by conferring a major selective advantage. However the evidence for a selective sweep involving *FoxP2* is no longer supported by a more extensive study by the original team (Atkinson et al. 2018) and is now known to be shared by Denisovans and Neanderthals, taking it back to at least 600,000 years ago before *Homo sapiens* and these lines diverged.

An indication of a key genetic switch which may have led to the increasing brain size of the *Homo* line has come from investigation of the gene family *SRGAP2a,b,c*, (Dennis 2012) involved in neocortex maturation, which is present in only one copy in chimps as well as other mammals, but has undergone three duplications in humans, the first daughter copy 3.4 million years ago around the time evidence of *Australopithecus* tool use seems to have occurred, and the second 2.4 million years ago around the time *Homo* is believed to have split off from *Australopithecus* and the third about 1 million years ago. The effect of the duplications of truncated copies appears to be that the duplications form a more complex regulatory system, which partially inhibits the action of the original, leading to a slower growing, larger brain with more complex ramified neurons, which can also migrate more rapidly during embryogenesis, leading to design features consistent with a larger more complex brain (Charrier et al. 2012). Several other brain genes may also prove to be duplicated in humans complementing this discovery.

A human-specific gene may be responsible for human neocortex expansion due to a single nucleotide change, which introduces a new splice variant. Neocortical neurogenesis involves two main classes of neural progenitor cells, apical progenitors (APs) and basal progenitors which are better suited for maximising neuron production. Accordingly, the evolutionary expansion of the neocortex is associated with an increase in the generation of BPs. The gene *ARHGAP11B*, which promotes basal progenitor amplification and is implicated in neocortex expansion, arose on the human evolutionary lineage by partial duplication of *ARHGAP11A*, which encodes RhoGAP. However, the lack of 55 nucleotides in the mRNA, which leads to loss of RhoGAP activity by GAP domain truncation also results in addition of a human-specific amino acid sequence. The 55 nucleotides are deleted by mRNA splicing. Hence, a single nucleotide substitution underlies the specific properties of *ARHGAP11B* that likely contributed to the evolutionary expansion of the human neocortex (Florio et al. 2016).

Fig 135: (Left) A The evolution of *SRGAP2*, showing the four human genes and the counterposed effects one maturing dendritic spines and another encouraging the formation of more immature spines resulting in a more complex expression. B: Splice variant duplication *ARHGAP11B* with unique tail enhancing basal progenitor mitosis and neocortical expansion (green). (Right) Evolution of *NOTCH2NL* and its affect on neurogenesis.

A set of three nearly identical genes found only in humans, *NOTCH2NL*, appears to play a critical role in the development of our large brains (Fiddes et al. 2018). These are found exclusively in humans and appeared between 3 and 4 million years ago, just before the period when fossils show a dramatic increase in the brain sizes of human ancestors. These genes belong to an ancient family of *NOTCH* genes, discovered in fruit flies and named causing notched wings. The human-specific genes were derived from *NOTCH2*, one of four mammalian *NOTCH* genes, through a duplication event that inserted an extra partial copy of *NOTCH2* into the genome in an ancient ape species that was a common ancestor of humans, chimpanzees, and gorillas. The partial duplicate was a nonfunctional pseudogene, versions of which are still found in chimp and gorilla genomes. In the human lineage, this pseudogene was revived when additional *NOTCH2* DNA was copied into its place, creating a functional gene. Gene conversion was likely

responsible for repairing a non-functional version of NOTCH2NL. After it was repaired, but before we diverged from our common ancestor with Neanderthals, NOTCH2NL was duplicated several times, resulting in four genes. Three of the four are active genes that direct the production of truncated versions of the original NOTCH2 protein. A complementary team (Suzuki et al. 2018) also focused on NOTCH2NL because of the importance of its ancestral gene, NOTCH2, in signalling processes that control whether cortical stem cells produce neurons or regenerate more stem cells. And they found that artificially expressing NOTCH2NL in mouse embryos increased the number of progenitor stem cells in the mouse cortex and can substantially expand the population of cortical stem cells, which in turn generate more neurons, a feature expected to distinguish between human and non-human cortical neurogenesis.

The role of micro RNAs which bind to mRNAs and thus are able to initiate a coordinated array of regulatory changes have been implicated in the differences in evolutionary rates of change between humans and chimps. Constitutive gene expression divergence is comparable between humans and chimpanzees. However, humans display a 3–5 times faster evolutionary rate in divergence of developmental patterns. Such accelerated evolution of human brain developmental patterns is twice as pronounced in the prefrontal cortex than the cerebellum, preferentially affects neuron-related genes, and does not depend on cis-regulatory changes, but might be driven by human-specific changes in expression of trans-acting regulators. Developmental profiles of miRNAs, as well as their target genes, show the fastest rates of human-specific evolutionary change. miR-92a, miR-454, and miR-320b are possible regulators of human-specific neural development (Somel et al. 2011).

Schroeder & Rogers Ackermann (2017, 2023) have shown that genetic drift, and, likely, small population sizes were important factors shaping the evolution of Homo and many of its novel traits, particularly those involving regulatory changes of many genes, for which neutral variation is prominent, although selection has played an essential role in driving adaptation to new contexts.

Brain size has swelled from the 500cc of Australopithecus. Homo erectus and his alter-ego Homo ergaster, went from a 750cc brain to 1250cc. The emergence of modern Homo sapiens, is accompanied by a slight decrease in brain size from an average of about 1500cc to 1400. Although this is well within the range of human variation between 1100 and 2000cc, it does suggest that some form of compactification has taken place. One view of this is that the development of culture and language has made it cognitively easier for the brain to assimilate the world around us. Another suggested (Ridley 2003 34) is that a reduction of aggression may be accompanied by a more neotonic physiology (tending towards embryonic form), as is noted comparing womens slightly smaller brain sizes than men, made up for by a higher proportion of grey matter neurons.

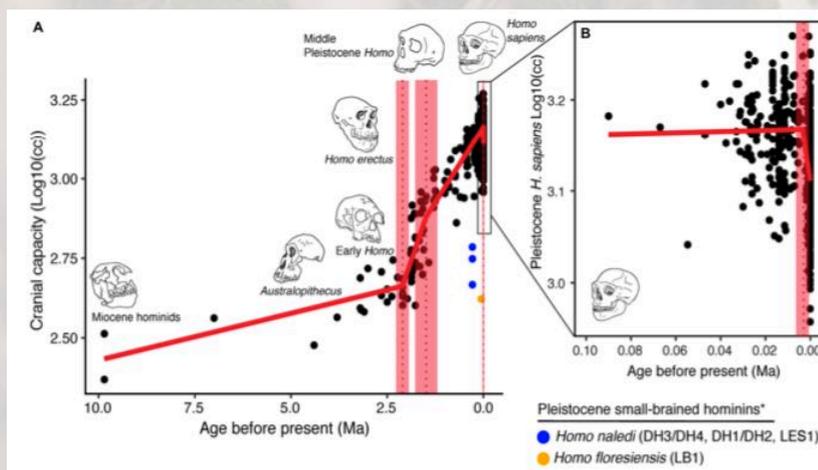

Fig 136: Variations in brain size, with a focus on a recent decrease DeSilva et al. (2021).

However, brain size is only an overall measure of brain complexity and intelligence and the size of the brain has both grown and shrunk in the lead up to the present. An important measure is the relative contributions of grey matter consisting of cell nuclei and white matter consisting of connecting axons. Zhang & Sejnowski (2000) have established a universal scaling law between grey matter and white matter of the cerebral cortex consistently

spanning several orders of magnitude in brain sizes across the mammalian kingdom, arising from an evolutionary requirement for compact arrangement of long axonal fibres.

Lüders, Steinmetz & Jäncke (2002) show that among people today, brain size correlates negatively with proportion of grey matter. Women have smaller brains with proportionately more grey matter so their white matter is relatively more efficient. Larger brains have a lower proportion of grey matter so their white matter was bulkier and relatively less efficient and their grey matter wasn't much larger as might appear from brain size.

*As expected, we found a significant sex difference for the absolute volumes of total brain, grey matter, white matter and CSF, with greater volumes for men. Relating these compartmental volume measures to brain volume resulting in proportional volume measures revealed **a higher proportion of grey matter in women**. No significant sex differences were found for white matter and CSF proportions. However, when the influence of sex was partialized out by regression analyses, brain volume explained 40-81% of the variance of the absolute grey matter, white matter and CSF volumes. Performing these regression analyses for the proportional volume measures revealed that brain volume explained ~16% of the variance in grey matter proportion. **Interestingly, the correlation between brain volume and grey matter proportion was negative, with larger brains exhibiting relatively smaller proportions of grey matter.** ... We suggest that brain size is the main variable determining the proportion of grey matter.*

This finding lends moderate support to the idea that some of the recent reduction in brain size could be due to evolving changes to improve the efficiency of axonal circuitry because (a) a larger brain is slower because the axonal routing takes longer, (b) there is a continuing selective pressure against unnecessary brain size, because of the metabolic load of a larger brain which already consumes 40% of the glucose metabolism and (c) because of a large brain size causing greater risks to the baby and mother during delivery.

There are many possible causes to explain such a reduction, changes in body size, diet, domestication reducing aggression. However, there is another major factor that may contribute and that is the negative effect of culture on brain size due to collective intelligence reducing the need for individual intelligence. DeSilva et al. (2021) note:

Reduction in brain size may not compromise cognitive performance if intelligence is an attribute of the society rather than the individual. Galton first described that the accuracy of decision making by human groups could exceed that of any individual group member. This concept of collective intelligence has since been elaborated in studies ranging from insects to humans. If brain production, maintenance, and operation costs are metabolically significant, then collective intelligence may reduce demands for neural tissue to support individual cognitive capabilities.

We suggest that group cognition lowered the demands for neural architectures required to support some aspects of individual intelligence and decision making. This effect may have become even more pronounced with the advent of writing ca. 5000 years ago, which falls within the estimated 95% CI for the pronounced reduction in Holocene human brain size (Fig 136). During human history, social groups became larger, social interactions more frequent, social networks more complex, and tracking relationships more demanding. A rise in sociocultural complexity was not due to particular individuals becoming more intelligent and culturally skilled, but because of the emergence of collective intelligence resulting from a growing population of interconnected humans and interacting human groups. As group size increases, interactions with a dynamic and exceedingly complex social landscapes result in increased demands on the brain. However, because of the metabolic demands of the brain, there may be limits to feedback loops between social network size and brain structure. If group decision-making generated adaptive group responses exceeding the cognitive accuracy and speed of individual decisions and had a fitness consequence, then human brain size may have decreased as a consequence of metabolic cost savings.

Population size expanded dramatically with the advent of agriculture, beginning ~10 kyr and grew exponentially from an estimated five million to over 100 million by 3000 years ago. This increase in population coincided with deterioration in individual health and increases in infection rate, pathogenic load, and virulence. It remains possible, then, that the high energetic cost of a heightened immune response, might have been a factor in Holocene brain reduction. In fact, Crabtree (2013a, b) proposed this immunity-for-intelligence trade-off in his controversial "Idiocracy Hypothesis," though this idea has been criticized on the basis of flawed assumptions (Kalinka et al., 2013; Mitchell, 2013). Gowdy and Krall (2013) draw parallels between the ultrasocial human superorganism, complete with division of labor and "economic organization around surplus" that arose in the Holocene and the sociobiology of agricultural eusocial insects, including some ants and termites.

Crabtree (2013a, b) cites the large number of X-chromosome genes, each of which results in clinical intellectual disability (ID) as an unstable chain of genes, rather than a robust self-compensating network, making the human genome vulnerable to the loss of any of them:

Perhaps the most effective way to estimate the number of genes in humans that are needed for full intellectual function is to rely on studies of X-linked intellectual deficiency (XLID). Because males have only one X chromosome, the effects of X-chromosome mutations cannot be rescued or compensated for by the second copy, in contrast to mutations on other chromosomes. Present studies indicate that mutation of about 215 intellectual deficiency (ID) genes on the X chromosome give rise to XLID and/or emotional disability [1,2]; this represents about 25% of the genes on the X chromosome. Of these, 86 have been characterized and do not seem to be neomorphs (a gain of inappropriate function). This gives a conservative estimate that about 10% of all human genes are implicated in intellectual function. Because mutation of any one of these genes can give rise to intellectual disability, it can be concluded that they do not operate as a robust network, but rather as links in a chain, failure of any one of which leads to intellectual disability. The X chromosome does not appear to be enriched for genes required for intellectual development, and therefore we can extrapolate that between 2000 and 5000 genes are needed for intellectual and emotional function.

Crabtree (2013c, d) has responded vigorously to his critics (Kalinka et al., 2013; Mitchell, 2013). His extension to 2000-5000 ID genes in the whole genome is likely a moderate overestimate because he assumed the X-chromosome was representative of the entire genome, however there are still a very large number of genes involved, so the concern

remains real. In fact the X-chromosome does have between 1.9 and 4.3 times as many ID or MR (mental retardation) genes, which in turn attests to a pivotal role for astute female reproductive choice in selecting for super-intelligence cited in the previous section. Hence the repression of this, under patriarchal culture, is very likely to be having a deleterious effect on human intelligence.

A novel test, in which Inlow J & Restifo L (2004), distributed unmapped MR disorders proportionately across the autosomes, failed to eliminate the well-known X-chromosome overrepresentation of MR genes and candidate genes:

It has been proposed that the human X chromosome contains a disproportionately high density of genes for cognitive ability. This proposal generated controversy as well as speculation concerning possible underlying evolutionary mechanisms, including the intriguing suggestion that female mate selection for high male intelligence helped accelerate the rapid rise of human cognitive abilities (Turner 1996; Zechner et al. 2001). Opponents, however, argued that all X-linked recessive mutations are simply easier to map and identify because their phenotypes are revealed in hemizygous males. Countering this view is an analysis (Zechner et al. 2001) showing a 7.2-fold X-chromosome bias for MR genes, whereas genes causing common morphological phenotypes have, on average, only a 2.4-fold X-chromosome bias.

To take this question one step further, we asked whether the apparent X-chromosome overrepresentation among the molecularly identified human MR genes [of around 4.3 times] would disappear if we accounted for the plausible possibility that numerous autosomal loci are “hiding” among the unmapped MR genes. We attempted to overcome the ascertainment bias that favors identification of X-linked genes by making simplifying assumptions that maximize the estimate of autosomal MR genes and minimize the estimate of X-linked MR genes. Even when these very conservative (i.e., biased toward autosomal) assumptions are used to estimate the chromosomal distribution of the unknown MR genes, a 1.9-fold overrepresentation of MR genes on the X chromosome remains. This result supports the hypothesis that the X chromosome contains a disproportionately high density of genes influencing cognitive ability.

Crabtree cites the cultural hive mind we have created, in which selection for individual intelligence is blunted in favour of collective intelligence, as well as demands of urban living in terms of immune competition as a result of epidemic diseases as contributing to intellectual decline:

When might we have begun to lose these abilities? Most likely we started our slide with high-density living, which was enabled by the transformative invention of agriculture. Selection may have begun operating on resistance to the diseases that naturally grow out of high-density living, switching the pressure from intelligence to immunity. It is also likely that the need for intelligence was reduced as we began to live in supportive societies that made up for lapses of judgment or failures of comprehension. Community life would, I believe, tend to reduce the selective pressure placed on every individual, every day of their life. Indeed that is why I prefer to live in such a society.

Several considerations could mitigate the validity of the argument that intellectual and emotional fitness are slowly decaying. For example, genes required for intellectual and emotional function could be needed for early development or even fertility, and would thus be maintained through selection. ... Another common counter-argument is that we are under constant selection for our intellectual traits. Intellectual capacity and emotional stability have mating advantages that would reduce the rate at which mutations affecting these traits become fixed in our genome. This is true, but I fear does not take into account the extreme selection required to maintain traits dependent upon thousands of genes with reduced heritability. A hunter-gatherer who did not correctly conceive a solution to providing food or shelter probably died, along with his/her progeny, whereas a modern Wall Street executive that made a similar conceptual mistake would receive a substantial bonus and be a more attractive mate. Clearly, extreme selection is a thing of the past.

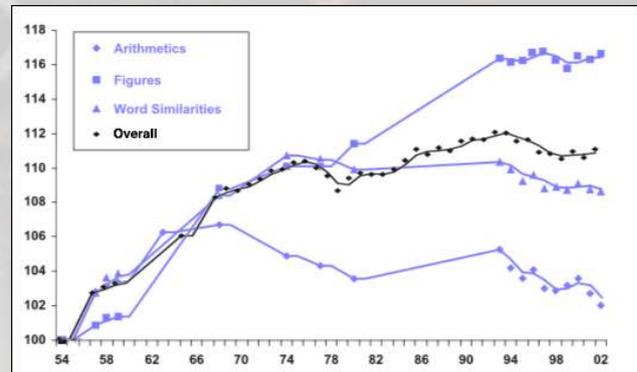

Gawdy & Krall's (2013) thesis is particularly stark, invoking a “hive mind” superorganism status for a human culture heading towards self-extinction:

The current geological epoch has been dubbed the Anthropocene—the age of humans. We argue that the roots of the Anthropocene lie in the agricultural revolution that began some 8000 years ago. Unique human psychological and cultural characteristics were present in our distant hunter-gatherer past, but in terms of the biophysical impact of our species, agriculture represented an unequivocal and decisive evolutionary break. With the transition to agriculture human society began to function as a superorganism functioning as a single unit designed by social natural selection to produce economic surplus. Where environmental conditions were permitted, early human agricultural societies followed the same pattern as a few social insects and exhibited explosive population growth, complex and detailed division of labor, intensive resource exploitation, territorial expansion, and a social organization favoring the survival and growth of the supergroup over the well-being of individuals within the group. Similar economic forces lie behind ultrasociality in social insects and humans—increased productivity from the division of labor, increasing returns to scale, and the exploitation of stocks of productive resources. Exploring the evolutionary mechanisms behind ultrasociality offers insights into the growth imperative that threatens the stability of the earth's life support systems.

Does this currently mean we have already incurred a significant loss of intelligence? Possibly not but probably a loss of some forms of intelligence related to individual survival. The Flynn effect (Sundet, Barlaug & Torjussen 2004) is the substantial and long-sustained increase in both fluid and crystallised intelligence test scores that were measured in

many parts of the world over the 20th century. Test score increases have been continuous and approximately linear from the earliest years of testing to the present. For example, a study published in the year 2009 found that British children's average scores on the Raven's Progressive Matrices test rose by 14 IQ points from 1942 to 2008. There are numerous proposed explanations of the Flynn effect, such as the rise in efficiency of education and better diet, along with skepticism concerning its implications. Some research suggests that there may be an ongoing reversed Flynn effect (i.e., a decline in IQ scores) in Norway, Denmark, Australia, Britain, the Netherlands, Sweden, Finland, and German-speaking countries, a development which appears to have started in the 1990s.

Fig 137: Overall Flynn effect begins to decline with marked falls in word and arithmetic scores (Sundet et al. 2004)

Bratsberg & Rogeberg (2018), analysing the effect in Norway, state that the Flynn effect and its reversal are both environmentally caused and that the trends are not due to a changing composition of families, and that there is at most a minor role for explanations involving genes (e.g., immigration and dysgenic fertility) and environmental factors largely fixed within families and that their influence is negligible compared with other environmental factors. Therefore the Flynn effect provides no reassurance that the underlying genetic basis of human intelligence is not under atrophy.

The outstanding difference between humans and all other species is the emergence of human culture. This introduces new kinds of challenges. Humans are a highly social species, so survival in the jungle has been overtaken by survival in the concrete jungle of human affairs. In many ways this is just as challenging, because Machiavellian intelligence, both creates many social niches and also creates chains of prisoner's dilemma paradoxes of survival. But it is also clear that human culture is providing services that are significantly blunting strong selection for individual intelligence on a wide demographic footing. Previously to survive in gatherer-hunter society while cooperating in small bands, the inability to survive in the wild and fend for a family would result in demise. In technological society the diverse intelligence skills required for all aspects of individual survival have been reduced to a much simpler set of options of being trained for a specific and sometimes menial action set, e.g. in an industrial process or routine office role. Human mate selection is no longer driven by astute females seeking brainier males, but macho brawn in the patriarchal mould, with female reproductive choice actively and violently repressed by the religious patriarchy as well.

We are thus fooling ourselves to think we are biologically more intelligent purely on the basis of the culture that we have co-evolved with. We have been overtaken by our own culture. All the products of culture we see, from the pinnacles of scientific discovery, to the elaborate technological processes that have enabled the digital age and a landing on the moon, have not arisen from an increase in individual intelligence, but chain reactions of discovery and manufacture in which a series of small insights create a technological process which then becomes automatically replicated to produce items, from heart-lung machines to cell phones, which we now depend on and can barely comprehend how to use, let alone understand how they are made, or how they work.

Climax Mammalian and Avian Intelligence

We are keenly aware that we are more intelligent than apes but when we examine the brains of elephants and dolphins and whales, which form the climax of intelligence of the Proboscidea and Cetaceans, their brain structure and complexity looks anatomically and physiologically very similar to, or even surpassing that of human brains.

While the large brains of elephants are dominated by cell numbers in the cerebellum so that, while their CNS numbers are much higher than humans, their cortical numbers are lower, the same is not true for cetaceans. Mortensen H et al. (2014) note:

*Possessing large brains and complex behavioral patterns, cetaceans are believed to be highly intelligent. Their brains, which are the largest in the Animal Kingdom and have enormous gyrification compared with terrestrial mammals ... we estimated the total number of cells in the neocortex of the long-finned pilot whale (*Globicephala melas*) brain. For the first time, we show that a species of dolphin has more neocortical neurons than any mammal studied to date including humans. We found that the long-finned pilot whale neocortex has approximately 37.2×10^9 neurons, which is almost twice as many as humans, and 127×10^9 glial cells.*

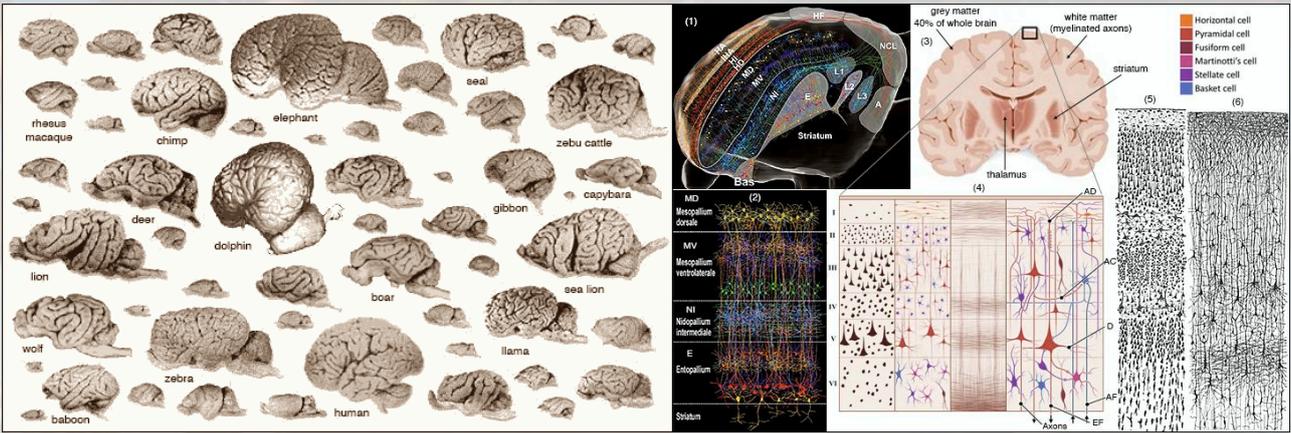

Fig 137b: (Left) Spread of mammal brains . The mammalian cortex folds more extensively with the volume of thalamo-cortical axons requiring increasing folding to compensate for the basal brain network volume, although primates have a superior ratio of cortical neurons to brain volume (inset fig138b). This is partially compensated for by smaller mammals also having smaller pyramidal neurons by a packing factor close to the square root of the linear size. E.g. a human is about 25 times as tall as a mouse is long and its pyramidal neurons are 1/2 the width, packing 4 times as many into the same cortical area. Hence the mouse actually has more cortical neurons for its relative brain volume than humans (fig 138b) although its cortex is smooth. (Right) Avian (1, 2) and human brains (3-6) compared for pallium/cortical neuronal structure (Güntürkün et al. 2021). Both have a layered structure but in birds this extends all the way to the striatum, while in mammals it occupies only the superficial cortex (1-4 mm mean 2.5 mm), overlaying massive white matter axons. (5) shows Nissl staining to show cell bodies in the visual cortex and (6) Golgi staining to show axons.

There is no basis to the notion that the spread of other mammals have inferior biological intelligence to *Homo sapiens*. The cerebral cortex is an evolutionary adaption shared by stem and all crown mammal species, with larger brains commensurately more folded to maintain proportionality between the area of the cortex and the increasing volume of basal brain connections. There are no dumb and smart mammals, but simply mammals displaying conscious intelligence, adapted to their ecological roles. What distinguishes humanity is the intervention of language and culture, as externally derived memetic processes, ultimately from the possession of fingers and opposable thumbs, enabling niche manipulation shared by founding primates. Smaller mammals have smoother cortices but similar relative numbers of cortical to basal brain neurons.

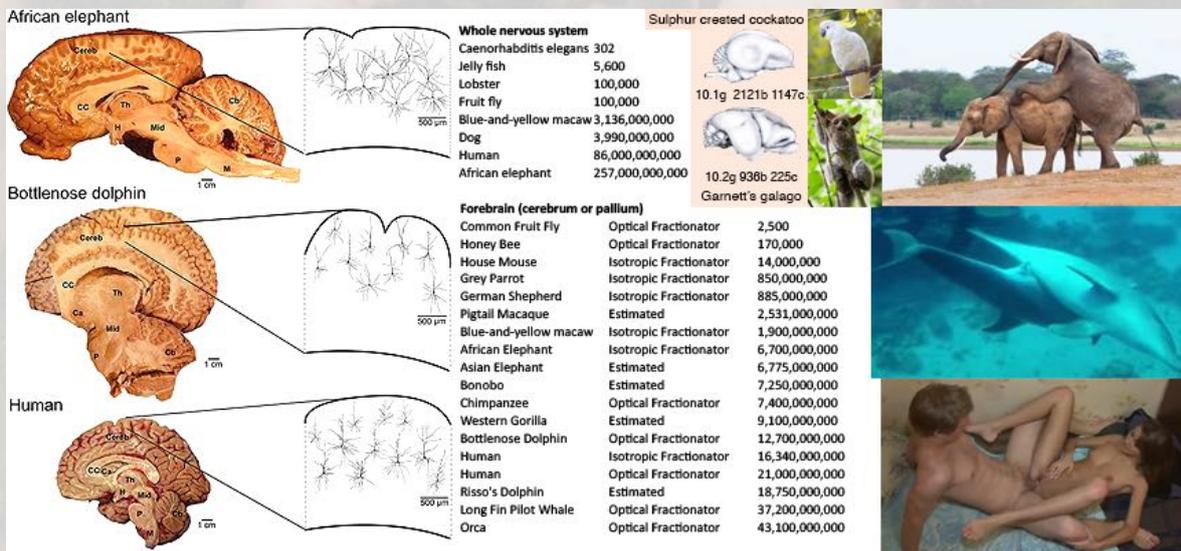

Fig 138: Left: Biological intelligence is not revealed or reliably measured by cultural complexity. Brains and cortical neurons of African elephant, Bottlenose dolphin and Human. Centre: Diverse whole brain and cortical neuronal numbers. The blue and yellow macaw forebrain neuronal density 1.9bn is comparable with the pigtail macaque 2.5bn, despite its brain weight being only 20.7g compared with 106g. Inset: The cockatoo and galago each have a brain weighing 10g but the cockatoo has 1.147bn cortical neurons, 54% of the whole brain, compared with 0.226bn in the galago representing 24% of the whole brain in both galago and human.

The key difference between humans on the one hand and elephants and dolphins on the other is human culture, both as language, which I contend in the next section has a strong cultural component as a memetic virus conferring rapidly evolving semantic efficiency; and niche and tool construction, which results in the civilisation that makes us think we are far more intelligent than the rest of life. This is a form of human exceptionalism that is deleterious to our survival.

Elephants have no fingers and no toes and can't use tools, except with their highly evolved trunks for plant foraging and drinking, so it's hard for them to make any kind of records. All cetaceans have the same problem – no limbs but fins and no way of making traceable records, so dolphins spend all their time playing sex games, of love and war and have very high intelligence but that's the limit of their culture and memes are really difficult to come by. Studies of the linguistic basis of cetacean clicks and songs remain uncertain how far these differ from other kinds of animal communication (Eskelinen et al. 2016, Janik 2013, King et al. 2021, Ryabov 2016).

We aren't necessarily more biologically intelligent than elephants and dolphins, except that our line of evolution resulted in fingers, tools and niche construction, and a tear away process of memetic cultural evolution, in which grunts and mothers crooning to their babies resulted, through finely tuned human vocal articulation, just as our use of fingers, resulted in complex language taking over our brains from the outside, as conceptual cultural memetic “viruses” and produced the kind of world we now live in, complemented by our tools and the trappings of village and then urban culture, which is now reducing us to troglodytes of our own making, unless we protect the biosphere.

In fact we can see as parents just how easy it is for language to become established because *Homo* has another unique physiological “invention” that is as significant as fingers and thumbs were to the first primates – the absurdly expressive human voice box. There is evidence from *Homo erectus* and *ergaster* of this evolving long before human culture (Fielder & King 2004). Recordings of ape calls show just how different we are in terms of vocal semantics, although semantics is obvious in primate expressive behaviour eg. Capuchins in fig 150b. Monkeys, such as Vervets have functionally referential alarm calls (Price et al. 2015), but only marginally in apes such as chimps (Slocombe & Zuberbühler 2005). These abilities go back to the lemurs (Walton & Kershenbaum 2019), suggesting humans may have retained this underlying conserved vocal trait socially, as well as opposable fingers and thumbs.

We are NOT “hard-wired” for semantic language. It is a rapidly evolving cultural “virus” we communicate, as Kirby and Christiansen (2003, Christiansen & Chater 2008) make clear next section. When we first taught our kids, we said “no” and stopped them and then we said “mama” and “papa” and pointed to each of us just as mother pumas do, to teach their cubs to hunt by example. That is where our kids immediately grasped the elusive concept of “semantic” meaning and it was all over, from there, bar the endless chatting since. Neither are ape kids so different from human kids in terms of family dynamics. Just as the fingers made technology, so the voice box made linguistic culture and rational thought, by reverse cultural viral memetic takeover – par excellence! Thus the combination of fingers and accurate referential alarm, calls rather than humanity being a super-intelligent elite, seem to be key to the birth of culture.

What is the Future Spearhead of Conscious Evolution?

Comparing humans, dolphins and elephants, we have seen that what distinguishes humans is not just their large brains but their phenotypic ability to give expression to tool use and to thus design new ecological niches exploiting the natural habitat and the species it contains, through processes such as gathering and hunting, and the generation of social cultures associated with language, particularly between mothers and their babies and young children as the key to developmental intelligence, then used widely in the social group to establish and maintain trusting relationships.

This would justify the focus on *Homo sapiens* itself as the key dominant species in whose evolution the future of biospheric evolution has become entwined, except for the crippling and potentially fatal flaw that human exploitation of the biosphere has become not only a threat to the biosphere as a whole through habitat exploitation, wilderness degradation, wild species destruction, climate crisis, and pollution, not to mention the risks of nuclear warfare, but has also become an ever more brittle instability for humanity itself, due to increasing dependence on technology to drive our ever longer and more tenuous food distribution chains, and our energy demands to keep an increasingly complex global society, prone to multiple tipping points of urban food supply break down, international conflicts arising from increasing scarcity of resources, epidemic disease due to a single large fluid mass society, and the debilitating effects of climate and biodiversity crisis itself. This is now becoming compounded by increasing dependence on unsustainable forms of artificial intelligence, prone to even more brittle break down in the event of any disruption to the social system. This leaves our species completely vulnerable to any major disruption, from an asteroid or cometary strike, through a large magma eruption like that that gave rise to the Deccan traps, severe climate overheating tipping points with loss of the polar albedo and others. It raises the question of whether *Homo sapiens* has a viable evolutionary future, or whether the biosphere may need to depend on simpler more prolific species, with faster genetic turnover and adaption and shorter reproduction times, from rodents, to cockroaches, or even single-celled eucaryotes, as an ultimate future option for biospheric survival.

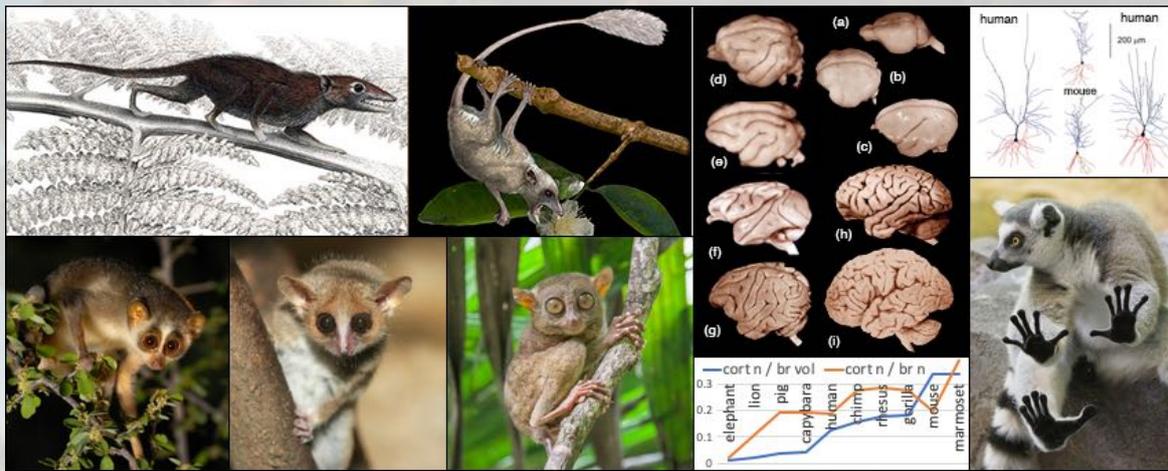

Fig 138b: Top left: *Juramaia* a eutherian placental fossil from 160 mya ago (Luo et al. 2011) followed by *Eomaia* 125 mya (Ji et al. 2002). Top right: *Dryomomys*, 55 mya after the Cretaceous-Tertiary extinction, the most primitive primate known from good fossil material. The first known primate fossil, *Purgatorius*, dating from 65 mya, known only from isolated teeth and jaw. The earliest primate from molecular clocks dates at 90 mya but adapted to take into account fossil evidence it dates to 81.5 mya, well before the Cretaceous-Tertiary extinction (Tavare et al. 2002). Lower row: slender loris, mouse lemur and tarsier. Right: Brains of (a) mouse, (b) tarsier, (c) marmoset, prosimian (d) ring-tailed lemur and (e) slow loris. Anthropoid (f) rhesus monkey, (g) lar gibbon (h) chimp and (i) human. Primates display cortical folding homology. Larger mammals, from rodents (capybara) to primates (humans) have greater folding in larger brained species to preserve cortical surface to brain volume ratios (Brain Museum). Lower right: Comparison of the ratios of cortical neurons to brain volume and total neuron count in elephant, lion, pig, capybara, human, chimp, rhesus, gorilla, mouse and marmoset. These show mice and marmosets, despite their smooth brains and small size, share optimal cortical n/brain vol ratios, even compared with humans. In addition mouse CA1 pyramidal cells are only half the dimensions of human ones (top-right) so neuronal densities in small animals are higher (Benavides-Piccione et al. 2020). Small primates are thus ideally placed to evolve compact highly intelligent brains by comparison with other mammalian families. Opposable thumbs for grasping objects are widespread in primates, with strepsirrhine pro-simians having pseudo-opposable thumbs (lower far right). *Darwinius masillae*, an Eocene primate fossil between prosimian and simian, had hands and feet with highly flexible digits featuring opposable thumbs and halluces (Franzen et al. 2009). The brain to body ratio is high in primates, with rhesus macaques having a similar figure to humans.

In New Zealand Aotearoa, because of its evolutionary isolation the region had no apex mammal predators and only small reptiles, some bats and flightless birds, such as the iconic kiwi, which are now ravaged by rodents, mustelids and possums, meaning that humans have had to take on the burden of becoming apex predators of feral introduced invasive species. One can then ask the question is it worth saving such exceptional species, because species extinction is after all a natural consequence of evolutionary change, as well as new species emergence. But this isn't about any fundamentalistic naturalist agenda of protecting dumb wild animals, but the entire future of conscious existence on our beloved blue-green planetary paradise we are putting a stake.

However any form of intervention to allow species extinctions involves a tortured and complex decision because survival of the biosphere depends not just on an individual species' reproductive success but on how a climax ecosystem generates robustness to sometimes apocalyptic planetary environmental crisis through the sheer diversity of its interacting niches. It becomes a perilous game to cast lots on evolution itself to try to sustain it from the consequences of human devastation. But are there some species, however threatened, that are really essential?

Traditional fossil records suggest the mammalian radiation of the dominant placental species occurred only after the dinosaur extinction, implying it took an astronomical intervention to result in the mammalian dominance, primate emergence and hence human evolution, rendering any notion of humanity as a hot evolutionary target capricious. However it is clear the earliest mammal ancestors arose long before this, some 225 mya ago, as small shrew-like species living off small organisms, such as insects (Novacek 1997). There has been continuing debate between molecular clock evidence suggesting an early diversification and fossil evidence existing only since the demise of the dinosaurs. The current picture remains controversial but a picture is emerging of an early genetic origin with little phenotypic diversification in the Jurassic-Cretaceous epoch of the dinosaurs, although the stem and crown placental groups had become established, followed by rapid phenotypic diversification after the dinosaur extinction, as diverse new niches became available (Tavare et al. 2002, Ji et al. 2002, O'Leary et al. 2013, Luo et al. 2011, Halliday et al. 2019, King & Beck 2020), thus explaining the discrepancy. Primates become key for their fingers complementing their brains that became key in human tool use, and cultural emergence, so primates remain key future evolutionary targets.

The most “primitive” primates are the wet-nosed strepsirrhines, consisting of the lemurs of Madagascar, galagos (bushbabies), pottos from Africa, and lorises from India and southeast Asia. Many of the species living today are endangered due to habitat destruction, hunting for bushmeat, and live capture for the exotic pet trade. Strepsirrhines are behaviourally diverse, although all are primarily arboreal (tree-dwelling). In the warmer Eocene there were many species which have become extinct, in our cooler climates, so they could diversify in a warmer world heading back toward Eocene temperatures provided we protect them now. The sister dry-nosed group of haplorhines, including Tarsiers are also targets. Otherwise, in a cataclysmic planetary crisis, we are back to rats and mice.

Implications for the human future, Where could this end up for humanity?

1. Going down the Hive-Mind Rabbit Hole

How far do we want to go down the road of becoming a smaller-brained hive-minded species dependent on our brittle unstable, implicitly unsustainable, machine technology to survive? Given that we are extremely maladapted to the survival of the biosphere in a form that is likely to sustain us long term, this seems to be a terminal Fermi demise.

2. Violating our Evolutionary Paradigm

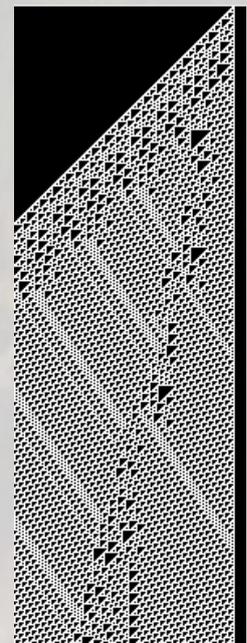

Human super-intelligence and cultural emergence appears to have occurred in a context of astute female reproductive choice complemented by mutual mate choice. The patriarchal epoch exemplified by Eden asserts an overthrow of this to achieve male paternity certainty. This has resulted in all sorts of negative selective pressures. The current situation is girls of reproductive age not making astute reproductive choices because the media and the group culture preaches a doctrine of macho males and awed females getting laid, that is mindless patriarchal fantasy and intelligence suicide. The history of the last 10,000 years already described in the previous section shows diverse manifestations of this. It is deleterious for an XY chromosomal species with a massive polarisation of reproductive risk and investment to culturally repress astute female reproductive choice. Religions are the prime offender and need to be exorcised for their sins, but also the notion of males driving culture reinforced by militarisation and the dominance of men in strategic decision making. This is also a recipe for a downhill slide into oblivion.

3. Biological Intelligence vs Cultural Chain Reaction: Will we split into two species?

This discussion has hinged on two issues (a) Human brain size changes and (b) Are humans the most intelligent species? Most people who claim humans are the most intelligent species, are doing so on the basis of products of cultural chain reaction, but they are denying the influence of culture and claiming it is based on our biological intelligence. These comments are simply reinforcing the fact that we are becoming more and more dependent on cultural chain reaction processes, in which many humans contribute a small amount of intelligence to accumulative manufacturing processes as a hive mind and the results look stunning but don't in any way represent the ongoing demographic level of biological intelligence across the human population as a whole.

Fig 139: The edge-of-chaos 1-D CA rule 110 is a universal computer (Chen et al. 2012, Cook 2004).

If you glance at the cellular automation on the right, you will see a system having no intrinsic intelligence, simply a rule. The 1-D cellular automaton with decimal rule 110, taken from my [CA Mac app](#) is able to do **incredibly complex things**, because it's a universal computer. Give it the right (static) initial conditions, it can produce any result a digital computer can do, including states much more complex than its initial conditions. Its binary code is 01101110 for the eight possible previous three cell states of 0/1. I.e. 111 → 0 110 → 1 etc. But is it “intelligent”? It's “natural” intelligence is no more than its binary code plus the arrows above, but its “cultural” intelligence is unbounded above except by np-complete problems that are computationally intractable.

The failure of human society to recognise that cultural production of complexity is not a direct function of individual human biological intelligence on a demographic footing, but of increasingly automated processes that could lead to AI takeover, not because AI got so smart, but because we got so dumb on a demographic basis. Sexual selection involves endless recombination, so unless we form an elite and bifurcate into two species by selective breeding in an equally dystopian Handmaid's Tale, one smart and inventing the technology and the other dumbed down, living like ants, so we are again in serious trouble. Better to merge symbiotically with the biosphere as living beings and actually survive.

Gene-Culture Co-Evolution

(a) The Emergence of Language

The emergence of spoken language has been associated both with female gatherers talking about their relationships down the grape vine while on gathering forays, when the men were out on a hunt, the only sounds of which were disguised animal signals, and with mothers speaking to their babies (Hrdy 2003). Animal studies have also suggested social empathy as a catalyst (Erard & Matcic 2018) and a combination of the two (Johansson 2021).

Selective scenarios for the emergence of natural language are bounteous. Language evolved to facilitate cooperative hunting. Language evolved as a costly ornament that allows females to assess male quality. Language evolved as a substitute for the grooming exhibited by other primates when groups got too large. Language evolved to promote pair bonding, to aid mother-child communication, to gossip about others, to expedite toolmaking, as a tool for thought, or to fulfill countless other functions or purposes (Laland 2017 176).

While the basis of language has veered from hardwired concepts such as universal generative grammars, and a battery of cerebral toolkits specifically to articulate and interpret spoken word, based on Broca's and Wernicke's language areas, there is no good rationale why a purely genetic and natural selection process in the absence of the evolutionary effect of language itself can provide an explanation. This leads to gene-culture co-evolutionary theories (Kirby & Christiansen 2003, Laland & Brown 2002, Pinker 2010, Deacon 1998, Christiansen & Chater 2008), in which language itself becomes a kind of meme-like parasite provocateur transforming human intelligence, exploding our ecological niches and giving rise to the phenomenon of culture.

[James] Hurford argues that language evolution needs to be understood as a combination of both biological pre-adaptations – that is, biological changes that may not be adaptive by themselves – and learning-based linguistic adaptations over generations. He points to several possible biological steps prior to the emergence of language: pre-adaptations for the production of speech sounds (phonetics), for organizing the sounds into complex sequences (syntax), for forming basic and complex concepts and doing mental calculations with them (semantics), for complex social interaction (pragmatics), and for an elementary ability to link sounds to concepts (symbolic capacity). Once humans were language-ready with these pre-adaptations in place, language systems would have grown increasingly complex due to the process of transmitting language across generations through the narrow filter of children's learning mechanisms (Kirby and Christiansen 2003).

We argue that [universal grammar] UG could not have arisen either by biological adaptation or non-adaptationist genetic processes, resulting in a logical problem of language evolution. Specifically, as the processes of language change are much more rapid than processes of genetic change, language constitutes a "moving target" both over time and across different human populations, and, hence, cannot provide a stable environment to which language genes could have adapted. We conclude that a biologically determined UG is not evolutionarily viable. Instead, the original motivation for UG – the mesh between learners and languages – arises because language has been shaped to fit the human brain, rather than vice versa. Following Darwin, we view language itself as a complex and interdependent "organism," which evolves under selectional pressures from human learning and processing mechanisms (Christiansen & Chater 2008).

Laland (2017) highlights the vast difference in vocal fluency that casts humans and monkey species distinctively apart from the relative paucity of such communication in higher apes:

When the natural communication systems of primates are examined, for instance, no straightforward increase in complexity from monkeys to apes to humans is observed. Many researchers characterize great ape communication systems as more limited in range than those of monkeys. For example, monkeys, but not other apes, have functionally referential alarm calls, although whether monkey calls are truly referential like human language remains contested. This particular ape-monkey difference makes biological sense. Great apes are larger and stronger than monkeys, and hence are less vulnerable to predation. Apes almost certainly didn't evolve referential alarm calls because they had comparatively little to be alarmed about. Indeed, there is little that is learned at all in the vocal communication of nonhuman apes. 18 Apes do possess gestures to initiate play, for instance, or when infants signal they wish to be carried—many of these gestures have learned elements. However, apes seemingly do not use their gestures referentially, nor do their gestures exhibit any symbolic or conventionalized features.

Laland ties this to the very earliest phase of human increase in brain size associated with tool-making:

The latest thinking on the evolution of early Homo suggests that increases in brain size were coupled with increased toolmaking and stone transport, dietary expansion, and greater developmental plasticity (the flexible adjustment of development to environmental conditions). This means that there would be plenty to teach, because our hominin ancestors subsisted on a broad omnivorous diet and were reliant on a large number of extractive foraging and tool-using skills. This period in human history was the dawn of cumulative culture, when our ancestors first began manufacturing stone tools, using the flakes to butcher carcasses for food and in a variety of other ways. In other words, it was the beginning of the phase in which (according to our analysis of the evolution of

teaching) cumulative culture would help make teaching widely adaptive. Here, then, is a setting in which teaching among close relatives could be beneficial across a broad range of contexts.

In his chapter on the evolution of intelligence, Laland cites the following six factors as key to evolution of human intelligence grouped in three categories, constituting "cultural drive" in turn shaping human genetics: (a) social (social learning, tactical deception) (b) technical (tool use, innovation) and (c) ecological (extractive foraging, diet depth). These are combined into the notion of "primate g" which effectively becomes general intelligence. Here he has essentially broadened the competitive notion of Machiavellian intelligence, which he still accepts is central, with other obvious mechanisms of feedback including social copying, tool use and foraging, placing an emphasis on social learning, particularly high-fidelity copying, in relation to group size and long generation times, noting that primate longevity correlates with social learning rather than general intelligence. While acknowledging the role of Machiavellian intelligence, Laland's lack of awareness of the pivotal role of sexual selection in promoting both intelligence and a loving pro-social society, noted in the previous section raises the question over the assumed benefits of cultural evolution over the sexual selection aspects gatherer-hunter evolutionary psychology, which has sustained us over longer time frames and left a clear imprint in our sexual physiology and pursuit of sexual love.

The crucible for the early language evolution Laland invokes, rather than the small-brained Australopithecines, with a cranial volume of some 450 cc similar to other apes, would appear to be the major push made by Homo erectus and his alter-ego Homo ergaster, went from a 750cc brain to 1250cc close to our own average size of around 1400cc. Analysis of erectus skulls and the discovery of a hyoid bone involved in speech vocalisation is also consistent with an increasing use of language in erectus (Broadfield et. al. 2001), complementing a 1.6 million year old Homo ergaster skeleton, which does have some evidence of Broca's area (Taylor 1996 41).

Dunbar (2022) has a more precise analysis of the features and timing:

Speech requires two key capacities: the ability to produce long exhalations without having to take a breath and the capacity to control the articulation space in the mouth and upper throat by altering the position of the jaw, tongue and glottis. These are under the control, respectively, of the thoracic nerves in the upper chest and the hypoglossal nerve in the base of the skull. ... Three other anatomical markers are of interest for speech. One is the position of the hyoid bone that anchors the top of the larynx to the base of the tongue. In monkeys, apes and human infants, it lies high in the throat (which allows them to breathe and swallow at the same time without drowning themselves), but after weaning it drops low in the throat in humans (as a result, adults cannot drink and breathe at the same time). This low position is what allows us to produce certain vowel sounds, and vowels are crucial for human language. The other two indices are components of the inner ear, and hence our ability to hear fine distinctions in others' speech. These are the area of the base of middle ear bone known as the stapes and the size of the cochlea (the curled-up organ in the inner ear), both of which determine the range of sounds that can be heard. ... In fact, these five anatomical markers all appear to switch from primate-like to human-like with the appearance of archaic humans (Homo heidelbergensis) some 500,000 years ago.

Henrich (2017) demurs on the role of teaching in the emergence of language in his review of Laland's book:

I worry that it may overestimate the centrality of teaching and language for social learning, especially early in human evolution. My concern arises from the fact that, although teaching—broadly defined—does exist in some form across diverse societies, most of the research on pedagogy, parenting, and socialization derives from populations that are Western, educated, industrialized, rich, and democratic (WEIRD). In contrast to small-scale societies, WEIRD people rely heavily on intense verbal tuition, positive feedback, and active instructional interventions (3). This bias may skew our understanding of the role played by direct tuition and verbal scaffolding in cultural transmission. Further, numerous social norms, rituals, and technical skills are culturally transmitted without teaching or language (4), especially in small-scale societies.

Henrich (2016) argues that the secret of our success comes from culture, with cultural evolution and genetic evolution driving one another. The result of an immense period of this gene-culture co-evolution is not a "really smart, though somewhat less hairy, chimp", but "a new kind of animal" which has arrived because it is "better to be social than smart". The big difference between baby humans and chimpanzees is not in mastering abstract ideas, like quantity or causality, but that we are "prolific, spontaneous and automatic imitators, even willing to copy seemingly unnecessary or purely stylistic steps":

Humans are adaptive cultural learners who acquire ideas, beliefs, values, social norms, motivations, and worldview from others in their communities. To focus our cultural learning, we use cues of prestige, success, sex, dialect, and ethnicity, among others, and especially attend to particular domains, such as those involving food, sex, danger, and norm violations. .. Humans are status seekers and aware strongly influence by prestige. But what's highly flexible is which behaviors or actions lead to high prestige. ...The social norms we acquire often come with internalized motivations and ways of viewing the world (guiding our attention and memory), as well as with standards for judging and punishing others. People's preferences and motivations are not fixed.

Darwin, the founder of the evolutionary approach, speculated that language was potentially an invention (1904 60): "Man not only uses inarticulate cries, gestures and expressions, but has invented articulate language, if indeed the word invented can be applied to a process completed by innumerable steps half consciously made". Morten Christiansen questions the need to invoke a Chomskian generative grammar. Instead, he argues, language has adapted to utilise more general cognitive processing capacities that were already part of our ancestors' brains before language came along. Among these, he focuses on 'sequential learning' - the ability to encode and represent the order of the discrete elements in a sequence. This ability is not unique to humans: mountain gorillas, for example, use it in the complicated preparation of certain spiky plant foods, where a sequence of tasks is required to remove the edible part. Language, he says, is a 'non-obligate mutualistic endosymbiont' - a kind of evolutionary structure like a 'symbolic virus'. Kirby suggests our brains are not so specifically designed for language and that we appear to be biologically adapted to language because language which evolves much faster than biology has culturally adapted to us, gaining semantic power and representational efficiency as it evolves. It also provides a common explanation for both spoken and written language which has evolved too recently to have arisen from long-term genetic evolution.

Introducing their approach, Kirby and Christiansen (2003) note:

There are an enormous number of communication systems in the natural world (Hauser, 1996). When a male Tu'ngara frog produces "whines" and "chucks" to attract a female, when a mantis shrimp strikes the ground to warn off a competitor for territory, even when a bee is attracted to a particular flower, communication is taking place. Humans as prodigious communicators are not unusual in this respect. What makes human language stand out as unique (or at least very rare indeed) is the degree to which it is learned. From a design point of view, it is easy to see the advantages of providing instructions for building mechanisms for language acquisition rather than the language itself. Human language cannot be completely innate because it would not fit in the genome. Worden (1995) has derived a speed-limit on evolution that allows us to estimate the maximum amount of information in the human genome that codes for the cognitive differences between us and chimpanzees. He gives a paltry figure of approximately 5 kilobytes. This is equivalent to the text of just the introduction to this chapter. Finally, we look at the implications of our work for linguistic and evolutionary theory. Ultimately, we argue that linguistic structure arises from the interactions between learning, culture and evolution. If we are to understand the origins of human language, we must understand what happens when these three complex adaptive systems are brought together.

*A meme impels its bearer to broadcast it, and it mutates in some recipients: a sound of a word, or a phrase is randomly altered. Perhaps, as in Monty Python's *The Life of Brian*, the audience of the Sermon on the Mount mishears the "Blessed are the peacemakers" as "Blessed are the cheesemakers." The new version is more memorable and comes to predominate in the majority of minds. It too is mangled by typos and speako's and hearo's, and the most spreadable ones accumulate, gradually transforming the sequence of sounds. Eventually, they spell out, "That's one small step for man, one giant leap for mankind". I think you'll agree that this is not how cultural change works. A complex meme does not arise by the retention of copying errors. If selection does not explain complex design in cultural evolution by itself, then it is of no importance. This is mistaken. There is no doubt that as people acquire and modify beliefs, ideas and values the variation that is generated can be highly non-random, and these non-selective processes shape cultural variation. But so what? Selection occurs anytime there is heritable variation that effects survival or reproduction (transmission).*

Various lines of evidence support such optimisation of representational and cognitive efficiency in existing languages. For example dependency length minimisation, in which words which depend on one another come closer in a sentence than random (Futrell et al. 2015), makes it easier to recognise meanings in both spoken and written sentences, although the efficiency of existing languages varies widely. Widely used languages such as English have evolved to simplify changes of tense, person, gender and number to avoid complex conjugation and declension of verbs and nouns. There is also evidence that the root of languages might be partly iconic rather than the arbitrary relationships between sound and meaning of traditional linguistic theories, so that words indicating slowness, descent or negative emotions have a falling pattern of intonation while those with the opposite have a rising one, like down as opposed to up. "Splash" provides a good example of a word whose spoken sound mimics its natural sound.

Languages as different as Danish and Hindi have evolved in less than 5000 years from a common Proto-Indo-European ancestor (Gray & Atkinson 2003). Yet it took up to 200,000 years for modern humans to evolve from archaic Homo sapiens. The latest estimates of the oldest skulls discovered, from the Omo river by Richard Leakey are 196,000 years (McDougall et. al. 2005). Pinker (2003) notes steps of this type in the experiments of Martin Nowak's group (Nowak & Krakauer 1999) in establishing both sequential symbols such as vowels and consonants to form a word and positional syntax in which words describing single events give way to active characterisation of a type of event. Both are adaptive responses to informational crisis as a large number of symbols each associated with a single context or event involves too many similar symbols to adequately discriminate one from another. The emergence of such structures could in turn have enabled the semantic enfolding of the rational mind. Reading written language is clearly such an adaption of visual pattern recognition and other skills.

Corballis (2002) suggests language arose from a selective convergence of these diverse attributes to give rise to semantic language, possibly also accompanied by a convergence of other faculties such as mental perspectives of others, consistent with an early common origin of click sounds (p 106). Gestures like the shrug are also ancient responses, while smiles, and snarls with all their dimensions from appeasement to tooth threatening exposure go all the way back through our primate relatives. Laughter is an example of a central chaotic and explosive emotional response to contradiction, or surprise, which is suggestive of an ancient origin, earlier than language as we know it, in sharing emotional reactions, which also appears to have a basis in sexual courtship and family bonding:

*"Women laugh most in the presence of men they find attractive.
Men are the leading laugh getters, women are the leading laughers"* Robert Provine

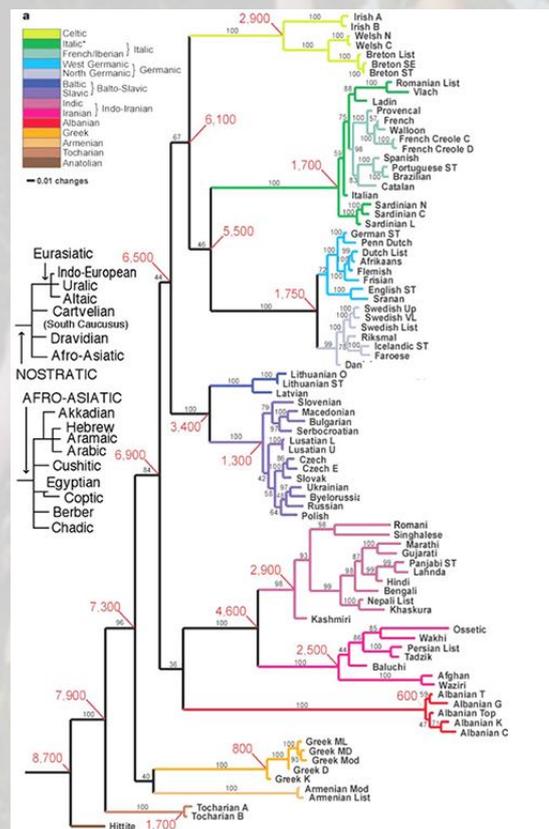

The advent of semantic exchange would place a huge new evolutionary burden on all areas of the cortex by exploding time, space and society into an historical process in which more and more contexts, individuals and situations came to be named and hence distinguishable from one another. Such a language involution would then place a burden of selection on larger brains which could handle the new and diverse complexities of a world imbued with historical and semantic meaning requiring slowed foetal development and a new awareness of social and sexual relationships and their implications. We can see the germ of this complexity in ape societies, such as grazing gelada baboons, where there are a host of cries indicating all manner of interactions, from courtship, through male competition, to emotional 'social contracts' of mutuality, reciprocation, aggression and reconciliation, as well as group warnings about predators. Among these, sexual courtship and competition are both very strong and also very subtle fleeting yet highly focused influences, as a glance at a female macaque inciting an extra-alpha 'safari' coupling behind the alpha males' backs indicates.

Fig 140: Evolutionary tree of the Indo-European languages (Gray & Atkinson 2003).

This is also broadly consistent with the fact that brain processing about lexical semantic information still appears to be at a striking advantage for experience-based representational structures (i.e., encoding information about sensory- motor, affective, and other features of phenomenal experience), with little evidence for independent taxonomic or distributional organisation (Fernandino et al. 2022).

This approach to the emergence of language supports a general role for Machiavellian social interactions, with a core emphasis on reproduction and sexual selection driving the burgeoning complexity of semantic language, consistent with both Geoffrey Miller's sexual selection ideas and honesty and deceit in wider social contracts. Consistent with this view is the fact that the sneakiest monkeys have the largest brains (Byrne & Corp 2004). Dunbar (1996) suggests that, as neocortical size increases, more subtle social and political strategies, such as tactical deception come into play. As a result, lower-ranking individuals are able to find loopholes in the social dominance hierarchy. Their special cognitive capacity makes them able to improve their reproductive success, in spite of lower rank - in line with the Machiavellian Intelligence hypothesis (Whiten and Byrne 1988, 1997). Boehm (1999 182) comments that the political invention of egalitarian society during this process enabled such individuals to forgo or invoke strategies of social deception, suggesting that lower ranking coalitions bluffed or forced their way, as male coalitions of chimps can do, to form large, stable and purposeful coalitions which are at the root of our social egalitarianism, politics and morality.

Laland (2017) brings this whole thesis back to its foundation in gene-culture co-evolution:

I described how the manufacture and use of stone tools may have played a vital role in human evolution by generating coevolutionary feedback between cultural practices and genetic inheritance, and thereby contributed to the emergence of language. Our tool knapping study supported the hypothesis that a gene-culture coevolutionary dynamic between tool use and social transmission was ongoing in human evolution, starting at least 2.5 million years ago and continuing to the present. Indeed, this entire book is one long advocacy for the significance of evolutionary feedback that encompasses a cultural drive mechanism initiated by natural selection that favored accurate and efficient copying. That selective feedback propelled the evolution of cognition in some primate lineages, and ultimately was responsible for the awesome computational power of the human brain. That propensity was fashioned by millions of years of gene-culture coevolution.

(b) Niche Construction, Habitat Destruction Gene-culture Co-evolution and the Anthropocene

Niche construction is a concept from the extended evolutionary synthesis, where species not only exist within an ecological niche existing in the natural environment, but by their own activities alter the niche to promote their own survival. Niche construction can provide both physical and cultural extensions of a species niche. Because in symbiotic existential cosmology subjective conscious volition has physical efficacy, this becomes a conscious intentional process.

Fig 141: Examples of niche construction: Devil's gardens in the Amazon. The ant, *Myrmelachista schumanni*, which nests in *Duroia hirsuta* stems, creates devil's gardens by poisoning all plants except its hosts. A worker ant attacks a plant by lethal injection (inset). It bites a small hole in the leaf tissue, inserts the tip of its abdomen, and releases formic acid, which kills the plant. Male South African Weaver Birds construct elaborate hanging nests which avoid predators, to attract mates. A beaver dam. Beavers hold a very specific biological niche in the ecosystem: constructing dams across river systems. Human destruction of the rain forest to make monoclonal palm oil plantations Sabah.

For niche construction to affect evolution it must satisfy: (1) the organism significantly modifying environmental conditions, (2) these

modifications influencing one or more selection pressures on a recipient organism, and (3) there must be an evolutionary response in at least one recipient population caused by the environmental modification. Niche construction can be viewed as an evolutionary process that works in conjunction with natural selection. Evolution entails networks of feedbacks in which previously selected organisms drive environmental changes, and organism-modified environments subsequently select for changes in organisms. The complementary match between an organism and its environment results from the two processes of natural selection and niche construction. The effect of niche construction is especially pronounced in situations where environmental alterations persist for several generations, introducing the evolutionary role of ecological inheritance. The development of many organisms, and the recurrence of traits across generations, has been found to depend critically on the construction of developmental environments such as nests by ancestral organisms. Ecological inheritance implies that organisms inherit two legacies from their ancestors: genes and a modified environment.

Niche construction is recognised to have played important roles in human evolution, including the evolution of cognitive capabilities. It is immediately apparent that humans possess an unusually potent capability to regulate, construct and destroy their environments, and that this is generating pressing current problems (e.g. climate change, deforestation, urbanisation). However, human scientists have been attracted to the niche construction perspective because it recognises human activities as a directing process, rather than merely the consequence of natural selection.

Niche construction is a process by which gene-culture co-evolution can transform the evolutionary process. Examples of niche construction include the building of nests and burrows by animals, and the creation of shade, influencing of wind speed, and alternation of nutrient cycling by plants. Although these alterations are often beneficial to the constructor, they are not always. In the case of *Homo sapiens*, the process has had an unconstrained runaway effect driven by human evolution as a dominant species exploiting the natural environment. The trouble is that human niche construction has become wholesale habitat destruction. Despite climate, habitat and biodiversity crisis leading

towards a mass extinction on cosmological time scales, there is no sign that gene-culture evolution is producing the stability required for the biosphere to survive in evolutionary time.

Fig 142: Human niche construction has exceeded all ecological bounds and transformed or destroyed the natural ecosystems to produce agricultural, urban, mining and toxically polluted landscapes reaching an irreversible degradation of the entire concept of an ecosystemic niche, due to the impact of a single species.

Mathematical models have established that cultural niche construction can modify natural selection on human genes and drive evolutionary events in the process of gene-culture coevolution. There is now little doubt that human cultural niche construction has co-directed human evolution. Humans have modified selection, for instance, by dispersing into new environments with different climatic regimes, devising agricultural practices or domesticating livestock. For example, dairy farming created a selection pressure that led to the spread of alleles for adult lactase persistence. Many hundreds of genes have been found to be subject to recent selection, and human cultural activities are thought to be a major source of this selection.

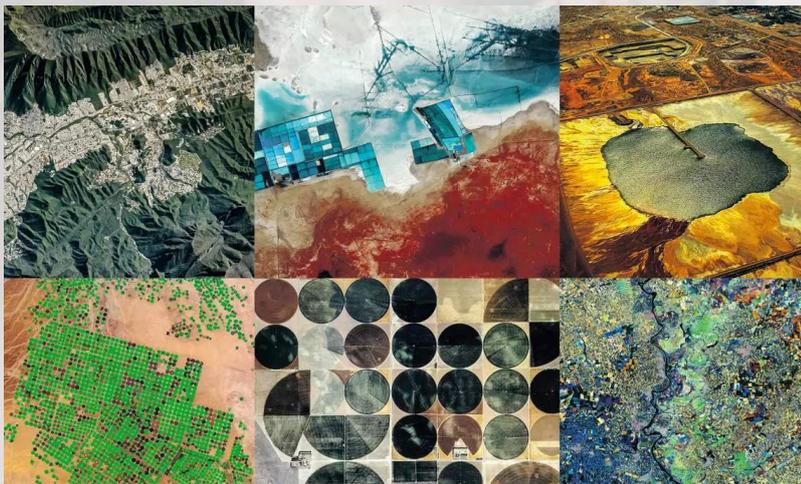

Fig 143: The Anthropocene: Eventually, these processes lead to their own cultural imposition on the planet, resulting in entirely synthetic “cognitive” rather than “experiential” landscapes (Guardian).

Laland (2017 243) gives a fitting account of the benefits and emerging costs of agriculture as niche construction: *Agricultural practices are examples of cultural niche construction that, as described in the previous chapter, can trigger evolutionary episodes in both the domesticates and, via selective feedback, in the human populations too. Cultural niche constructing processes that contribute to plant domestication include selective collecting, transporting, storing, and*

planting of seeds; setting fire to grasslands and forest, either intentionally or accidentally; cutting down trees; tilling; weeding and the selective culling of competing species; irrigation; and creating organically rich dump heaps. The skills and information that underlay these processes were passed from one generation to the next through a combination of teaching, imitation, stories, myths, and ritual,⁵¹ with the knowledge base regularly accumulating and being updated. Over time, these agricultural practices had an impact on the plants, which underwent a series of dramatic changes, such as major increases in size of the plant or its seeds, faster seed germination, simultaneous ripening of the seed crop, and so forth. The changes benefited both species by increasing the fitness of the plant community and elevating its yield. Sowing seeds in prepared substrates, for example, both induces changes in germination and dispersal mechanisms through inadvertent artificial selection, and helps the tended plants by increasing their likelihood of being included in next year’s seed stock.⁵² The increased yield, in turn, encouraged humans to perpetuate the practices that maintained or increased plant productivity, thereby triggering natural selection that modified human digestive enzymes. However, the methods of sowing selected seeds and harvesting plants inadvertently imposed selection on the crops that eventually left many inviable when in open competition with wild counterparts, and hence utterly dependent on humans.

The same reasoning applies to animals, where domestication again selected for increased yields of animal products, such as milk, but also a variety of other traits, including lowered reactivity to environmental stimuli and a dependence on humans for survival and reproduction. The protection provided by corrals and pens, and selection of animals that were easy to manage, again modified the impact of natural selection on animal breeds. When removed from anthropogenic settings, that selection left the animals concerned much more vulnerable to predation.

But he is vastly underestimating the jeopardy here. Not only have the selectively bred strains become dependent on humans but they have become mono-cultured, often losing natural disease resistance and the evolutionary diversity

that wild plants have to survive on evolutionary time scales. Worse still, the cultivated plant and animal varieties and habitat destruction generally have led to the genetic diversity of the wild relatives being severely compromised, so that the future viability of the entire niche construction of agriculture looks increasingly uncertain unless resolute corrective action is taken. Finally, although agriculture supported a larger population, their nutritional diet was inferior to gatherer-hunter societies and they tended to become smaller and suffered more parasites and epidemic diseases.

Laland & Brown (2002 245-249) note the transition to gene-culture coevolution as a coherent discipline: *Gene-culture coevolution is like a hybrid cross between memetics and evolutionary psychology, with a little mathematical rigour thrown into the pot. Like memeticists, gene-culture coevolution enthusiasts treat culture as an evolving pool of ideas, beliefs, values, and knowledge that is learned and socially transmitted between individuals. Like evolutionary psychologists, these researchers believe that the cultural knowledge an individual adopts may sometimes, although certainly not always, depend on his or her genetic constitution. ... Moreover, selection acting on the genetic system is commonly generated or modified by the spread of cultural information.*

They place it as a central theoretical construct in the divergent views of differing social science disciplines:

For most social scientists 'culture' is a given. The notion that much of the variation in the behaviour of humans is brought about by their being exposed to divergent cultures is so widespread and intuitive that it appears beyond dispute. Culture is regarded as a cohesive set of mental representations, a collection of ideas, beliefs, and values that are transmitted among individuals and acquired through social learning. In contrast, most sociobiologists and evolutionary psychologists are united by the belief that the transmitted elements of culture exert either a comparatively trivial influence on human behaviour, or that whatever influence they have is so strictly circumscribed by genes that there is no need to take account of the dynamic properties of culture. For human behavioural ecologists, culture is viewed as a flexible system that produces the most adaptive outcome in a given environment and that can be altered over a relatively short period of time in response to environmental change. Others, such as many behaviour geneticists, treat 'culture' as the dross that is left over when the 'more important' genetic influences on behaviour have been isolated. 'Culture' is usually lumped together with individual learning and other environmental effects on behaviour into a ragbag labelled 'nurture', to be contrasted with genetic sources of variation. For proponents of gene-culture coevolution, many of these other biological perspectives are misguided. Too much culture changes too quickly to be feasibly explained by genes, while the fact that different behavioural traditions can be found in similar environments would appear to render environmental explanations of behaviour impotent a lot of the time.

They thus state a convincing case for the approach and both meaningful in biological evolutionary terms and in terms of key cultural forms of evolutionary change:

Our capacity for culture is a unique adaptation. It allows us humans to learn about our world rapidly and efficiently. Human beings don't have to scour their environment for sources of food and water, devise their own means of communication, or reinvent technological advances from first principles. Our capacity to acquire valuable skills and information from more knowledgeable others, such as parents, teachers, or friends, as well as indirectly via artefacts such as books and computers, furnishes us with a short cut to adaptive (and sometimes maladaptive) behaviour. Advocates of gene-culture coevolution share with memeticists and the vast majority of social scientists the view that what makes culture different from other aspects of the environment is the knowledge passed between individuals. Culture is transmitted and inherited in an endless chain, frequently adapted and modified to produce cumulative evolutionary change. This infectious, information-based property of transmission is what allows culture to change rapidly, to propagate a novel behaviour through a population, to modify the selection pressures acting on genes, and to exert such a powerful influence on our behavioural development.

Democratic Capitalism, Commerce and Company Law

Life has existed on earth for a full third of the universe's lifetime. The reason for this stability is twofold. Firstly, unlike larger short-lived stars which gave us our rich array of atoms in earlier supernova explosions, the sun is a small very long lived star with only very slowly evolving brightness. Secondly and more pertinently, life is genetic and genetic inheritance and evolution is cumulative over generations. It is also extremely conservative, striving to preserve genetic encoding through error correcting enzymes with evolution occurring only differentially through occasional adventitious beneficial mutation amid recombination to escape Muller's ratchet.

This means a lion cannot turn overnight into a lamb, nor can a tiger eat an antelope and metamorphose into a shark. However companies possess no such genetic stability and can liquidate their assets in the face of crisis and turn to entirely different occupations, as appeared to be the case when a Canadian fishing firm devastated the cod fishery and then cashed up its stock of assets and entered another kind of business such as prawn farming. They can also consume one another in takeovers to become entirely new corporate giants. This lack of long-terminability. Moreover the cumulative dynamics of genetic organisms generates long-term ecological relationships, which provide non-linear feedbacks that tend to stabilise complex relationships and increasing species and genetic diversity in

biospheric symbiosis. We may consider predators and disease-bearing parasites as evidence for the brutality of nature, but the ecosystemic relationships tell another story. Without predators such as lions, the population of gazelles will enter boom and bust as they eat out all the available fodder leading to their wipeout in escalating episodes of famine. This was intriguingly illustrated in the return of wolves to Yellowstone spurring the recovery of the bears. The removal of the wolves had caused the elk population to explode, consuming all the berries the bears depended on for their vitamins leading to a loss of fitness. But an ecosystem consisting entirely of economic predators cannot survive.

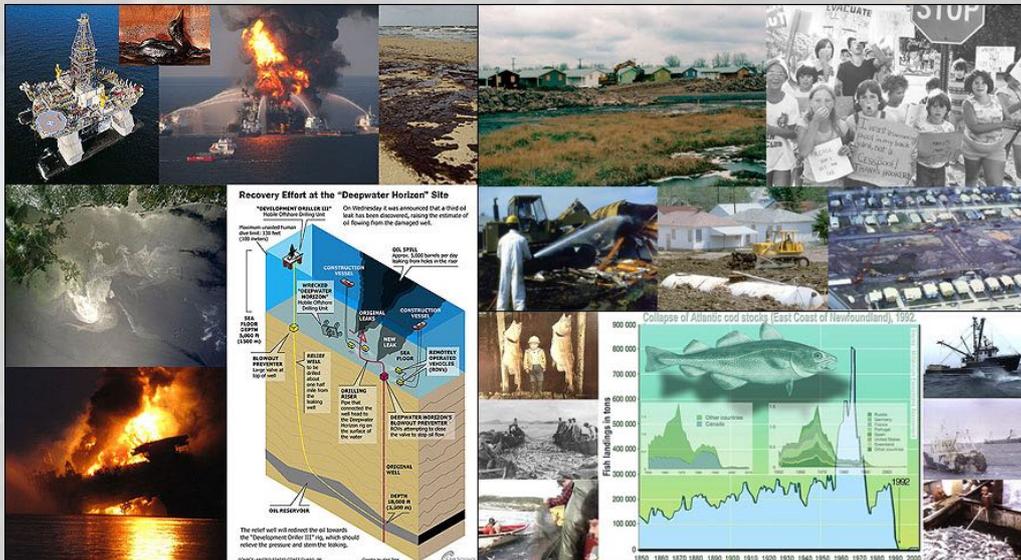

Fig 144: While the impact of corporate operations is clear in the figures in the anthropocene cultural niches, the lack of responsible corporate action causes other profound unintentional forms of collateral damage. (Left) The Deepwater Horizon oil spill of 2010 shows us how lethal misadventure and devastating environmental damage can occur when corporate responsibility becomes fragmented into self-serving cost-cutting conflicts of interest when large transnational corporations hire other large transnational companies as contractors in highly sensitive engineering projects, given a lack of effective monitoring from the federal government agencies that commissioned the projects in the first place. The Deepwater Horizon oil spill in the Gulf of Mexico on the BP-operated Macondo Prospect, is considered the largest accidental marine oil spill in the history of the petroleum industry. A 2017 report in Science puts the damage at \$17.2 bn. The consolidated trial's first phase began on February 25, 2013, to determine the liability of BP, Transocean, Halliburton, and other companies, and to determine whether the companies acted with gross negligence and willful misconduct. As of September 2014 Halliburton has reached a \$1.1 billion settlement over its role in the 2010 spill. Deepwater horizon was caused by failures of due care when the regulating officials got into bed with the corporations, causing widespread pollution costing billions of dollars to seal and clean up. (Top right) Dioxin pollution by Hooker Chemical in the Love Canal, Niagra was converted into a Faustian pact, when the land was sold for a nominal \$1 to a financially strapped school board on condition no responsibility would be taken by the company for any pollution. In 1978 crusading liberal journalist Micheal Brown discovered an alarming incidence of birth defects among residents living near the site. He advised the local residents to create a protest group, which was led by resident Karen Schroeder, whose daughter had about a dozen birth defects. The New York State Health Department mounted its own investigation and found an abnormal incidence of miscarriages. A survey conducted by the Love Canal Homeowners Association found that 56% of the children born from 1974–1978 had at least one birth defect. In one case, two out of four children in a single Love Canal family had birth defects; one girl was born deaf with a cleft palate, an extra row of teeth, and slight retardation, and a boy was born with an eye defect. Ten years after the incident, New York State Health Department Commissioner David Axelrod stated that Love Canal would long be remembered as a "national symbol of a failure to exercise a sense of concern for future generations." In 1988 United States District Judge John Curtin found Occidental who had taken over Hooker, jointly and severally liable for clean-up costs under CERCLA. In 1995 Occidental Petroleum agreed to pay \$129 million in restitution. The real cost of the cleanup is estimated at \$250 million. (Lower right) Fifty years ago, children in Newfoundland could catch fish by dipping a basket into the ocean. By 1992 Canadian research vessels were sweeping the seas in vain, finding not a single school of cod in what was once the world's richest fishery. The destruction of the Grand Banks cod is one of the biggest fisheries disasters of all time. Although the cod fishery supported workers for hundreds of years, a variety of changes occurred during the 20th century that made the industry much less sustainable than ever before. Foremost among these were advances in fishing technologies that dramatically increased the ability of fishers to find and harvest large quantities cod. By 1980 the Newfoundland fishery was dominated by three large complexes, each propped up by provincial government funds and bank loans: Fishery Products, Nickerson-National Sea Products and Lake Group. The fear of having to allow foreign fleets into Canada's exclusive economic zone if there was any surplus fish, as stipulated under the law of the sea, ensured the rationale would be that there would be no surplus fish. This is a classic tragedy of the commons enacted by the Canadian federal government for capitalistic purposes. Ultimately the companies supporting this collapse of the cod fishery converted their operations to becoming providers of seafood in the foodservice market, offering shrimps, crab, lobsters, shellfish and fish and fish products including seafood starters, sea cuisines, nuggets, oven ready products, and others to America's largest restaurant chains and national distributors.

Climax diversity is the cosmological apex of complex system generation, in which human society stands at the pinnacle. We can continue to coexist in this complex system only if we fashion our economic and developmental impacts in a way that maintains the long term stability of the living systems on which our continued existence depends. By contrast with the cumulative stability of genotype, and incremental evolution by mutation and natural selection, the capitalist economy is based on a purely social model of competing fragmented democracies. Company law stipulates a democratic basis for a group of shareholders to incorporate and sets out a legal and financial basis for them to pursue business based on the two nested democracies of the general meeting and the board of directors who are accountable to the shareholders, at least in principle. In larger companies, there is also a line-managed hierarchy of employees, forming a pyramid from the CEO at the apex down through the executive branch to salaried workers.

We now turn to how corporate business operates, to try to understand its role in survival of humanity and the biosphere over evolutionary time scales as gene-culture co-evolution. In the interests of private enterprise in a democratic society elected by the common will, the general principle is to allow legal entities to be constructed which can collectively perform the same roles of intentional agency that genetic individuals possess in an evolving human society. Outside this framework only the limits of government regulation provide highly varying degrees of protective feedback intended to guarantee a modicum of corporate accountability and responsibility, lacking in company law itself, for example in fair trading acts, clean air acts, and environmental protection acts. However these are in turn subject to political and commercial influence and often act too late to prevent the collateral damage.

Corporate competitiveness, by contrast with genetic mutation and natural selection, is a much more primitive form of selectivity, which does have a degree of survival of the fittest optimisation of efficiency, but in the complete absence of any cumulative genetic mechanism to ensure long term stability. The end results are thus much more prone to the breakdown of ecological complexity into huge conglomerate enterprises, with a high degree of collateral fallout due to short term impacts lacking any long-term foresight, or even any natural feedback mechanisms to ensure at least medium term stability.

Because they are vulnerable to manipulative share trading, companies are prone to mergers and acquisitions by friendly, or often hostile, takeover. These can be by competitors seeking to expand their niche in the market by eliminating competition, or providing collective efficiencies by laying off redundant staff, or they may simply be forays by hedge funds to gain strategic control over large profitable operations, or at another extreme can be asset stripping companies taking an undervalued company to pieces for its assets in plant, property and goodwill.

An Economist editorial of 1998 shows that the ease with which companies are born and fail is clearly one reason why Taiwan's total factor productivity had improved faster than that of all other Asian countries since 1960.

In 1991, 40% of Taiwan's chemical output came from firms that did not exist in 1986. One-third of the value of Taiwan's plastics production and half its output of fabricated metal products were also attributable to firms less than five years old. The newcomers established their place in the market by forcing older firms out of business. Firms that had accounted for 58% of Taiwan's chemical production in 1981 had left the business by 1991. In other sectors - including ones which were expanding rapidly overall - the carnage was even worse. Four out of five firms that manufactured clothing, metal products, textiles and plastics in 1981 either closed or changed lines of business over the next decade.

As the successful entrants tend to be more efficient than the firms that die, they boost productivity across the economy. Between 1986 and 1991, total factor productivity - the increase in output due to more efficient use of inputs such as labour and capital - in Taiwan's electrical-machinery industry rose 23.6%. Over a third of that, the researchers estimate, came from new firms pushing out less efficient ones. In the chemicals industry, where productivity growth was slower, a whopping three-fifths of the gain was due to the entry of highly efficient firms and the exit of stodgier ones.

But at the same time, this concrete jungle form of survival of the fittest shows no signs of providing any sort of long-term stability for the people, and the environment in which these companies operate or even for the market conditions on which these industries depend long term. Companies are simply incorporated agents founded by a contractual memorandum of understanding under company law, by their founding shareholders for their collective capital and revenue gain. They have no cumulative stability beyond the boardroom decision-making horizon and as they stand they have no covenant of responsibility to their workers, to the consumers of their products, to the general public and least of all to the natural environment in which they operate. Like a malignant cancer, the only principle on which they depend is relentless growth of income for the investors.

Given this one-sided covenant of corporations, only with their internal investors, it naturally falls to governmental regulation, to labour laws, the Clean Air Act, the Consumer Protection Act and other legislation to safeguard society from the deleterious impacts of corporate activity. When the new right call for an unregulated economy because this

will increase production and profitability, they are being deceptively disingenuous about the actual purpose of much of such regulation, which is designed to protect society the natural environment and our long-term future from potentially irreversible misadventure intrinsic to the corporate model, not simply to waste 'our' money on inefficient government interference.

There is no direct accountability to the workers, to the consumers, to society as a whole or to the planetary environment, unless laws covering questions like air, chemical or other forms of pollution, or environmental or social impacts are transgressed. Moreover the process is an unrealistic one based on pure financial competition, as if it is a society of predators with no prey apart from the living environment of the planet, its biological and non-renewable resources. There is no inbuilt sense of emotion, compassion, or foresight that we expect from live human agents, although these may also act psychopathically over issues of power and wealth.

But we have already seen that cultural evolution is much more rapid and unstable than genetic evolution which in terms of long-term survival remains the only incremental selective anchor that avoids triple witching hour instabilities leading to a [Fermi paradox](#) extinction. This leads to a completely unstable economic paradigm where corporations can engage tragedies of the commons (Hardin 1968), in a first-come first-served rush to exploit every profitable resource in sight for the benefit of their shareholders. We start with a model where we have genetic and phenotypic evolution of living organisms. Then we invent culture and witness the growth of gene-culture co-evolution between living organisms and their social culture. But then we introduce a third component, corporations which have no genetic identity but act economically as massively inflated versions of living agents assuming the same powers of autonomous agency we accept for ourselves as members of a free democracy. This means we now also have gene-culture co-evolution and a more insidious phenomenon of corporate-culture coevolution.

This is a primary situation where we have to come to terms with the inadequacy of purely contractual models of corporate agency and redesign corporate and economic investment to bring it into line with sustainable ecological and evolutionary principle of replication under incremental cumulative change subject to selective advantage in a context of overall symbiosis.

Wilson D et al. (2014) address this question in terms of evolutionary mechanics:

The growing scale of human society over the course of human history is increasingly being studied from a multilevel biocultural evolutionary perspective. According to Turchin (2003; 2005), empires tend to originate in geographical regions chronically at war, which acts as a crucible for the cultural evolution of exceptionally cooperative societies. The most cooperative expand into empires, but then cultural evolution within the empires favors practices that eventually lead to their collapse. New empires almost invariably form at the boundaries of old empires, whose centers become "black holes" for cooperation at a large scale. (See also Putnam 1992). In this halting fashion, with much carnage along the way, modern human society manages to function at a remarkably large scale. However, there is enormous room for improvement, especially with respect to global problems such as climate change and the worldwide economy. There will be no between-planet selection, so addressing these problems will require another kind of selection – the intentional selection of policies with large-scale and long-term human welfare in mind. Devising such enlightened policies will require a sophisticated knowledge of evolution. The challenges will be daunting, but at least in principle, the right kind of environmental intervention could cause the difficult to become easy, as is already beginning at the level of individuals and small groups.

A step in this direction is to achieve a consensus that the paradox of elaborate genetic innateness and an elaborate capacity for open-ended change can be reconciled through the concept of Darwin machines. Variation, selection, and heredity comprise an open-ended process capable of adapting organisms to their current environments according to the selection criteria. An evolutionary process built by genetic evolution must be elaborately innate for variation and selection to take place in a way that leads to genetically adaptive outcomes, on average. The immune system is an outstanding example of a Darwin machine that is both elaborately flexible and elaborately innate, providing a guide for how to study the human capacity for behavioral and cultural change. An important implication of Darwin machines is that a capacity for change requires certain forms of stability and homeostasis. For all inheritance systems, a complex system of interlocking processes is required to create variation, select according to certain criteria, and faithfully replicate the traits that have been selected. If this system breaks down, then so does the evolutionary process.

However his two cited examples fall far short of avoiding climate crisis, nuclear holocaust or the mass extinction of biodiversity:

We describe two interventions from the field of prevention science that successfully changed cultural practices at the level of counties, states, and nations. The first intervention reduced the very specific practice of convenience store clerks in Wyoming and Wisconsin illegally selling cigarettes to minors. The second intervention employs a population approach to improving parenting practices, which has been assessed in RCTs at the county level and is in the process of being implemented around the world. These examples fall short of addressing the gravest problems afflicting our planet, but they still show how evolutionary science can be used to accomplish intentional positive change above the level of individuals and small groups.

This has to go much further than Darwinian machines. *Homo sapiens* is already a natural species evolving by Darwinian principles but it has evolved through intentional selection as a species to dominate and exploit the natural world. The paradigm shift required is that cultural evolution can help bring this dominance to heel in the interests of the survival of the biosphere as a whole in cosmological time scales. We have to be able to turn to culture to achieve this because it is through our cultural heritage that we come to know and understand the potential mass extinction of life an unmitigated Anthropocene will bring about. But to do this, cultural evolution will have to engage a transformative paradigm of long-term incremental change that can balance and complement human dominance with biospheric symbiosis.

As a director of a company devoted to perpetual conservation and regeneration of a wilderness reserve, that had in the nineteenth century been native reserve land, and was still forested rather than farmed, I have designed a company constitution to care for this land in perpetuity, by drafting a constitution that binds the shareholders in a covenant to protect the land and its flora and fauna, not to sell it or wind up the company without unanimous approval and to pay the costs of upkeep and protection in the event the land is not profitable during any period. All decisions are made by unanimous signed agreement and are binding on the shareholders who can sell only at the consumer price index adjusted nominal value if they want to opt out. This gives an illustration how corporate structures can be given a measure of medium-term stability, albeit still on a much shorter time scale than evolutionary change and liable to demographic shifts in the shareholding as descendants become spread out over the face of the Earth. Commercial law can be redesigned to make financial enterprises a symbiotic part of a sustainable economy rather than a shrinking pool of predators endeavouring to grab the remaining resources before they all become extinguished.

So far, as we have seen, cultural evolution has remained an ephemeral player in the closing circle sustainability stakes, operating on much shorter and more unstable time scales than genetic evolution. Thus none of the processes we have examined, language, religion, or commerce have introduced any stabilising factors to the existential crisis we face. Symbiotic Existential Cosmology is designed to do precisely this because it is a comprehensive memplex, or symbotype, which far from being efficient, as the simple explanation of the Sabbatic Creation endeavours to do, is fully as complex as the living universe itself because it is a true and accurate cosmology of symbiotic existence. By being cosmologically accurate on evolutionary and cosmological time scales, it provides exactly the kind of dire warning that moral religions attempt incorrectly to do about eschatological reality and does so in a fully scientifically validated way that hopefully can stand the test of time.

Science, Religion and Gene-Culture Coevolution

Both science and religion are complex conceptual, symbolic and behavioural systems that cross human generations and have structured cultural influences affecting human survival and reproduction thus forming principal candidates for gene-cultural co-evolution. The scientific description of reality is a complex symbolic and conceptual system and the scientific method involves highly focussed forms of social behaviour associated with discovering the nature of reality around us. Likewise religion is a complex scriptural description that lays claim to an ultimate description of conscious (spiritual) reality accompanied by moral doctrines, devotional ritual and utopian aims of world redemption.

However their methods and approaches are very different and involve very distinct approaches, scepticism requiring proof or confirmation in science and affirmative belief frequently being essential for religious conviction, along with moral imperatives. This means that their mode of cultural evolution are contrasting and have distinct influence of humanity sometimes complementary but frequently discordant and in contradiction to one another. Nevertheless it is possible to give each an evolutionary treatment in terms of complex conceptual systems, either as memplexes, as Dawkins (1976) put it or symbotypes as DH Wilson et al. (2014) describe.

Science doesn't evolve by incremental mutation and natural selection, so much as theoretical innovation and empirical discovery, changing the natural context factually, often described as a scientific revolution, or paradigm shift. The standard of fitness tends toward theoretical or empirical truth about the natural and physical universe and the memes are the description of the universe themselves.

Nevertheless the interaction of scientists has been likened to an evolutionary process (Laland & Brown 2002 235):

Hull (1982) believes that scientific communities (e.g. Darwinians) are a collection of interacting scientists that have in common one or more memes (e.g. natural selection, Mendelian genetics, etc.) that are expressed in an evolving conceptual system (e.g. Darwinism). Researchers of today that are part of the Darwinian community have different views from their 19th-century counterparts. What unites them is the notion that they derived their beliefs from preceding Darwinians. But how can we tell whether a scientist is part of a scientific community? According to Hull (1982), in exactly the same way we can tell whether an individual organism is a member of a particular species:

Hull suggests that, to belong within the same lineage, scientists must have gained their information from each other, rather than merely holding similar views. Once such communities of scientists are defined, an evolutionary analysis of the development of ideas can begin. In fact, Hull argues that science is analogous to artificial selection rather than natural selection:

Just as the breeder consciously selects the organisms that he breeds in order to produce desired changes in his stock, the scientist chooses conceptual variants in order to improve his scientific theories. Both processes involve conscious, intentional choices even though many of the results in both cases may be unanticipated. (1982, p. 317)

A related, but more interesting, point is that memetic evolution is sometimes directed and intentional. Hull notes that the characteristic that commentators have in mind when they claim that sociocultural evolution, especially conceptual development in science, is 'Lamarckian' is that at least sometimes people actually notice problems and try to solve them. For instance, Pinker states: Memes such as the theory of relativity are not the cumulative product of millions of random (undirected) mutations of some original idea, but each brain in the chain of production added huge dollops of value to the product in a nonrandom way.

Science also, despite its declared commitment to the sceptical principle demonstrates its capacity to follow fashionable trend in assumptions that become undeclared beliefs, partly propelled by a publish or perish defensiveness to key mechanistic assumptions such as the physically causal nature of brain processes, when these remain unproven and likely unprovable.

However, it is religious belief and doctrine, and the underlying correspondences with spirituality as a complement, or even a deeper underlying truth than science, where the memetic sting comes to bite, as Laland & Brown (2002) note:

One sinister aspect of the meme's-eye view is that human beings seem to have been stripped of their ability to chose their own beliefs, values, and ways of life. Apparently, nefarious mind viruses are running our lives. The memes are choosing and manipulating us, not the other way round. Surely this surreal alternative perspective can't be the whole story? After all, our minds have evolved over millions of years. Wouldn't evolution at least have fashioned us with an ability to evaluate the alternative options and filter the available information that is adopted? If our bodies have an immune system to quell biological viruses, then shouldn't we expect our minds to have analogous defences to suppress rogue memes? The stance advocated by some memeticists may be missing some of the underlying complexity to human behaviour. Aunger (2000) identifies a key issue for memeticists to investigate: namely, whether the design in cultural 'adaptations' is best described as artificially selected by people to reflect their needs or as the unintended outcome of independent replicators. For instance, has the human brain been shaped to have certain properties that 'god' happens to fit, as suggested by Hinde (1999), or is the god concept merely a clever replicator, as Dawkins (1976) says?

In "Why Gods Persist" Hinde (1999) made a cultural field study of the reasons why deities persist in diverse religious and cultural traditions, from Monotheism, through Taoism and Buddhism, to ethnic religions, examining all the reasons from the life hereafter to meaning and morality. One of his major arguments concerned the components of religions (for instance, beliefs, ritual, values, and sociality) and whether the nature of these components could be understood using traditional biological principles.

1. **Attribution** We all seek to understand what is going on around us, and 'understanding' in this context implies attributing events to causes: it is reasonable to suppose that such attempts at explanation aided survival in the environments in which humans evolved.
2. **Control, self-efficacy** Of course, with the growth of scientific understanding we no longer need to find causal explanations for most natural phenomena, and for many people the need to postulate supernatural forces has been pushed back to events preceding the Big Bang. But while understanding the causes of events is an important contributor to the individual's peace of mind, it only takes one part of the way: the need to understand is closely related to a second issue, namely the need to feel in control of the events that influence one's life.
3. **Adversity** Closely related to the need to feel a sense of control, individuals need a means to cope with persecution, suffering and illness. Religion can help in such situations in several ways. It can assist the sufferer to accept the situation as inevitable, as God's will, and thus release him from the pain of kicking against the pricks. Alternatively, it can remove the devastating feeling that there is nothing that one can do, for at least one can pray and transfer the responsibility elsewhere.
4. **Mortality** Yet another major source for the attractiveness of deities lies in the desire for life after death. All organisms are adapted to strive for survival as necessary for reproduction. Even for a believer there may be uncertainty either about the fact of survival or about the nature of future existence, and uncertainty is likely to breed fear. Belief in a benevolent deity and a happy after-life can allay such preoccupations.

5. **Relationship factors** Humans seek social contact, and loneliness can be an important cause of distress. Indeed the sharing of experience is an important facet of all close relationships. The dissolution of a close relationship or bereavement involves a loss of part of the self-system. We continue to need attachment figures throughout life.
6. **Social factors** Religious belief is not just an individual matter. Beliefs are more or less shared with others, and there are powerful social forces that ensure that it should be so. There is often a gain to the individual from the sense of community, and a gain to the community from the effect of the shared beliefs on the loyalty of individuals: positive feedback is obtained from the consensual validation by others of the otherwise unverifiable beliefs.
7. **The meaning of life** Perhaps for many the apparent potency of religion can be encapsulated by saying that it gives a coherent meaning to life, though whether the need for meaning is primary, or depends on some of the issues previously mentioned, is an issue that need not detain us. Some argue that 'the search for significance is the overarching, guiding force in life'. It is often suggested that the tangible world is inadequate to provide material for the construction of credible compensation for non-available resources of the types mentioned above, that belief in a meaningful universe requires a designing agency, and that religions would lose their appeal if they lost contact with the supernatural.
8. **The diversity of the bases of belief** In the preceding paragraphs it has been argued that a number of basic propensities, which are probably ubiquitous in humans though differing somewhat between individuals and cultures, are basic to religious beliefs. To the extent that such is the case, religious beliefs can be seen as basically Darwinian.
9. **Belief and emotion** As mentioned already, in discussing beliefs it is difficult not to give the impression that belief is a solely intellectual matter. Nothing could be farther from the truth. We now know that the cognitive and emotional aspects of human psychological functioning are much more closely interwoven than was formerly thought to be the case, and this is especially important for religiosity. The very fact that religious beliefs involve counter-intuitive phenomena, and that people continue to adhere to beliefs which are contradicted by empirical evidence, suggests that intellectual conviction is not the sole issue.

Hinde's own views were summarized when he said, "it does not matter too much what you believe, for many different cultural beliefs bring meaning to believers' lives (though differences in religious beliefs can lead to horrendous conflict). But what does matter is how people behave." He also hypothesized about the evolution of pro-social groups, saying that groups in which members behave pro-socially and cooperate are most successful despite the conflict between the self and the group that's introduced by pro-sociality. He argued that this conflict was **managed by what is commonly called morality**.

However, it is Richard Dawkins who really set the meme lynx among the hawks and doves of religion, as Laland and Brown (2002 216) note:

One of the most controversial applications of memetic reasoning has been to account for religion. An organized and socially sanctioned belief in a god is to many people a given and a truth. This belief is not always regarded as something that is a legitimate focus for scientific enquiry. Even among non-believers, the idea that religions could be self-serving and self-perpetuating ideational complexes that hoodwink us into spreading their message is somewhat disturbing. Yet that is precisely what they have been argued to be by advocates of the meme's-eye view.

*This infamous account was first proposed by Dawkins in *The Selfish Gene* (1976), and elaborated in later writings. Dawkins argued that cultural selection would favour memes that gang up effectively into super-attractive coadapted meme-complexes, or memeplexes (Speel, 1995; referenced in Blackmore, 1999). Dawkins suggested that we could regard a church, with its architecture, rituals, laws, music, art, and written tradition, as just such a memeplex. He argued that the idea of a god and the religion memes that aggregate around it replicate themselves by providing convincing answers to life's great questions.*

Religions, however, are perhaps much more sinister than that. Dawkins suggested that they appear to employ various tricks, and co-opt other memes that facilitate their replication by the most dastardly of connivances. For instance, according to Dawkins:

an aspect of doctrine which has been very effective in enforcing religious observance is the threat of hell fire. Many children and even some adults believe that they will suffer ghastly torments after death if they do not obey the priestly rules. This is a particularly nasty technique of persuasion, causing great psychological anguish ... The idea of hell fire is ... self-perpetuating, because of its own deep psychological impact. It has become linked with the god meme because the two reinforce each other, and assist each other's survival in the meme pool. (Italics in original; 1976, p. 212)

Then there is faith: [Faith] means blind trust, in the absence of evidence, even in the teeth of evidence ... The meme for blind faith secures its own perpetuation by the simple unconscious expedient of discouraging rational enquiry. (Dawkins, 1976, pp. 212–13)

In fact, consider every possible trick that memes could employ to increase their frequency and memeticists suggest that such tricks are observed among organized religions (Aaron Lynch, 1996; Blackmore, 1999). They point out that memes would thrive that encouraged credit and praise to be heaped on individuals who read or learn verbatim texts describing the meme-complex; for example, the learning of Bible stories. Children adopt their parents' memes, hence specific religious memes may encourage having children, discourage abortion or contraception, encourage respect for elders, and discourage marriages between faiths. Memes could increase their frequency through conversions, so the most effective religions would be expected to place a premium on evangelicalism, proselytism, missionary work, and punishment of non-believers. Additionally, any challenge to the meme-complex might be treated extremely severely as, for example, in the case of Ayatollah Khomeini's fatwa on the author Salman Rushdie.

Blackmore (1999) asks her readers to reflect on why some minor religions went on to become great faiths, while the majority died out with the death of their leader. Her answer is that, of the many religious ideas, only some had packages of memes that were effective gimmicks for propagation, with particularly compelling (and difficult to disprove) explanations for life, and these became the major religions. Citing the work of theologian Hugh Pypier, Blackmore describes the Bible as the fittest of all books. She writes:

Western culture is the Bible's way of making more Bibles. And why is it [the bible] so successful? Because it alters its environment in a way that increases the chances of it being copied. It does this, for example, by including within itself many instructions to pass it on, and by describing itself as indispensable to the people who read it. It is extremely adaptable, and since much of its content is self-contradictory it can be used to justify more or less any action or moral stance. (1999, p. 192)

Attributing motives to memes is simply an intellectual stance adopted to help envisage which memes might be expected to have evolved. As Blackmore explains, religious memes did not, indeed could not, set out to succeed. She suggests that they were simply ideas and behaviour that had some utility in explaining the world and succeeded where others failed because they had the right combination of mutually supportive ideas that allowed them to be repeatedly passed on. It is worthy of note that there are other evolutionary approaches to understanding religion, many of which stress the advantages that religion bring to the individual (e.g. Hinde, 1999).

Natalie Angier (2002) in a New York Times interview with David Sloane Wilson had this to say of his more sympathetic view of religion, as expressed in "Darwin's Cathedral" (2002):

Dr. Wilson, a renowned evolutionary biologist, proposes that religion -- with all its institutional, emotional and prescriptive trappings -- ranks as a kind of mega-adaptation: a trait that evolved because it conferred advantages on those who bore it. But whereas evolutionary biologists traditionally view an adaptation as the outcome of a struggle between unevenly matched individuals -- say, between one polar bear with a cleanly cloaking white coat, and another with a slightly less effective form of camouflage -- Dr. Wilson sees religion as the product of group selection at work.

In his new book, Dr. Wilson argues that the religious impulse evolved early in hominid history because it helped make groups of humans comparatively more cohesive, more cooperative and more fraternal, and thus able to present a formidable front against bands of less organized or unified adversaries. By taking an evolutionary perspective on the subject, Dr. Wilson said, religion's twinned record of transcendent glories and shocking barbarities becomes comprehensible and even predictable, though not, perhaps, inevitable for the future.

In his own words he says: "I consider myself a communitarian, and there are many things I admire about religion, but no, I don't believe in God. I tell people I'm an atheist, but a nice atheist."

Wilson states that he has set out to demonstrate that a church can be thought of as an organism in an evolutionary sense:

*True love means growth for the whole organism, whose members are all interdependent and serve each other.
That is the outward form of the inner working of the Spirit, the organism of the Body governed by Christ.
We see the same thing among the bees, who all work with equal zeal gathering honey. —Ehrenpreis [1650] 1978, 11*

Religious believers often compare their communities to a single organism or even to a social insect colony. The passage quoted above is from the writings of the Hutterites, a Christian denomination that originated in Europe five centuries ago and that currently thrives in communal settlements scattered throughout northwestern North America. Across the world in China and Japan, Zen Buddhist monasteries were often constructed to resemble a single human body (Collcutt 1981). The purpose of this book is to treat the organismic concept of religious groups as a serious scientific hypothesis. Organisms are a product of natural selection. Through countless generations of variation and selection, they acquire properties that enable them to survive and reproduce in their environments. My purpose is to see if human groups in general, and religious groups in particular, qualify as organismic in this sense.

In summarising his evolutionary case as unifying systems, he notes this could extend to culture as a whole in all its aspects quoting culture itself as a defensive structure against chaos:

Cultures are defensive constructions against chaos, designed to reduce the impact of randomness on experience. They are adaptive responses, just as feathers are for birds and fur is for mammals. Cultures prescribe norms, evolve goals, build beliefs that help us tackle the challenges of existence. In so doing they must rule out many alternative goals and beliefs, and thereby limit possibilities; but this channeling of attention to a limited set of goals and means is what allows effortless actions within self-erected boundaries. —Csikszentmihalyi 1990, 91

This passage claims for culture in general what I have tried to show for religion in particular. The word religion is derived from the Latin "religio," which means "to unite or bind together" Related words used outside the context of religion are "religate" (to bind together or unite) and "ligature" (the act of tying or binding up). These meanings reflect the essence of the thesis of this book, like a hidden clue that was not discovered until the very end. However, religions are not the only systems that unite people into adaptive groups. I could have written a book on political organizations, business organizations, military organizations, sports teams, family groups, secular intellectual traditions, or even diffuse cultures as adaptive units. We therefore need to develop a general theory of unifying systems of which religion is a special case.

The idea that religions enable larger scale cooperative behaviour is universally supported. Many writers have expressed the view that moral systems in both animal and human societies function to reduce intra-social conflict leading in turn to inter-social dominance (Alexander 1987, Hinde 1999, Wilson 2002, Rossano (2010), Dunbar (2022).

But DH Wilson's point makes clear that other forms of social system also enable large scale cooperation, particularly social systems based on compassionate justice that people can recognise as good, so it doesn't explain why religion is advantageously desirable for the common good, integral to human culture or biology, or why a prescriptive religion that binds people in punitive ways to a more exacting extension of natural morality is superior to secular societies which can achieve the same ends. It is simply a fact of history that dominant empires have been associated with religions of one sort or another as social binding, arising from antiquity, even to the extent of ancient Rome switching to Christianity as a state religion under Constantine.

Nevertheless Wilson in his work (p 105) makes clear why the God-people relationship may not be factual:

The God-people relationship Ask a person to do something and the most likely response will be "Why?" An adaptive belief system cannot simply provide a list of behaviors but must also justify them. It might seem that the justification could be factual and straightforward: "Do this because it is good for you." However, this approach is unlikely to succeed by itself for a number of reasons.

First, it works best when the consequences of the behavior are well known: "Eat your spinach because it is high in iron and will make you healthy." Often the consequences of behaviors are not well known, and the most obvious short-term consequences (the bitter taste of spinach) can lead to a different conclusion than the more subtle long-term consequences (the health effects). An adaptive belief system must cope with ignorance in its justification of behaviors.

Second, a belief system that is adaptive at the group level must cope with the problem of cheating, which benefits some individuals at the expense of others within the group. Cheating is genuinely beneficial for the cheater (when he or she gets away with it), and therefore cannot be argued against on the basis of personal benefit. The same point can be made in terms of the "veil of ignorance" that Rawls (1971) used to explain the concept of justice. Ask self-interested people to design a society, subject to the constraint that they will be placed at random within the society, and they will design a just society. However, once placed within the society, they are subject to a different set of constraints and may well want to destroy what they previously created. This problem, which lies at the heart of multilevel selection theory, makes it difficult to justify the behaviors that constitute an adaptive group in terms of personal benefit.

Third, an adaptive belief system must be economical. The beliefs that justify the behaviors must be easily learned and employed in the real world. A fictional belief system that is user-friendly and that motivates an adaptive suite of behaviors will surpass a realistic belief system that requires a Ph.D. to understand and that leads to a paralysis of indecision.

Fourth, a fictional belief system can be more motivating than a realistic belief system. Imagine two individuals competing for a common resource. Even though the facts of this situation are easy to comprehend, regarding one's enemy as inhuman can be more motivating than regarding one's enemy as just like oneself.

Fifth, a fictional belief system can perform the same functions as externally imposed rewards and punishments, often at a much lower cost. For example, the usual means of raising money to serve the common good is in the form of taxes. Unfortunately, individuals who avoid paying taxes without punishment are always better off in material terms than solid citizens within the same group. Cheating can be prevented by punishment, but implementing a system for detecting and punishing cheaters can itself be costly. Another solution is to manipulate the cost of cheating in the mind of the average citizen. Groups governed by belief systems that internalize social control can be much more successful than groups that must rely on external forms of social control.

For all of these (and probably other) reasons, we can expect **many belief systems to be massively fictional in their portrayal of the world** (Wilson 1990, 1995). As I discussed, their adaptedness must be judged by the behaviors they motivate, not by their factual correspondence to reality.

This raises a series of problems:

Firstly do religions evolve and **what did they evolve from?**

Secondly religions, although they are moral social systems, which enable larger societies to cohere, also claim to be **cosmological descriptions of existential reality expressing ultimate truth**. If they are "massively fictional", they run the risk of dominating society and then leading it into an invidious outcome.

Thirdly, the very reasons being advanced why they are advantageous have nothing to do with their inner truth or otherwise, but precisely those **self-reinforcing social feedback loops** that memeticists cite as principal caveats about the role of religions. Wilson's five points are essentially social replicator rules and Hinde's nine reasons are the very avenues these rules seek to utilise.

Fourthly, the **question of morality**. Sociobiology teaches us that morality is a function of animal societies in which strategic bluffing occurs designed to inhibit internal competition to result in external dominance and survival. It is

not a cosmological imperative. Religion, by contrast asserts morality as a divine principle, ring fenced by virtuous inducements and dire consequences.

Fifthly, while Wilson uses examples such as Calvinism to highlight constructive pro-sociality not requiring oppressive punishments, the **history of religion is littered with homicidal punishments, and oppressive edicts** presenting no avenue of escape for members, so the notion that religions are more efficient by positive inducement fails the historical test, whenever prescriptive religions show their teeth and claws in their true colours.

Sixthly, the notion that humanity has evolved to **be genetically predisposed to spiritual or religious concepts**, or that the brain is or is "hard-wired" to do so has not been scientifically established.

Seventhly, although Wilson's citing of the reformation is an example of a type of evolutionary change within Christianity, **paradigm shifts in religions are exceedingly rare** over time scales of millennia, because religions are set up to zealously resist evolutionary change or re-interpretation as heresy, apostasy or blasphemy, unlike science where new ideas are assessed on their empirical or theoretic evidence, so that religion attempts to frustrate its own evolution, with the religious assault on evolutionary science, on the basis of the mythical and incorrect Sabbatical Creation, being a suitable case for treatment.

Eighthly: Religious views of nature and sexuality are in conflict wth reality

Ninthly religions, especially evangelical Christianity are in a collision course with nature in which evolution and the sanctity of the Tree of Life is denied.

The Evolution of Religions and the Consequences

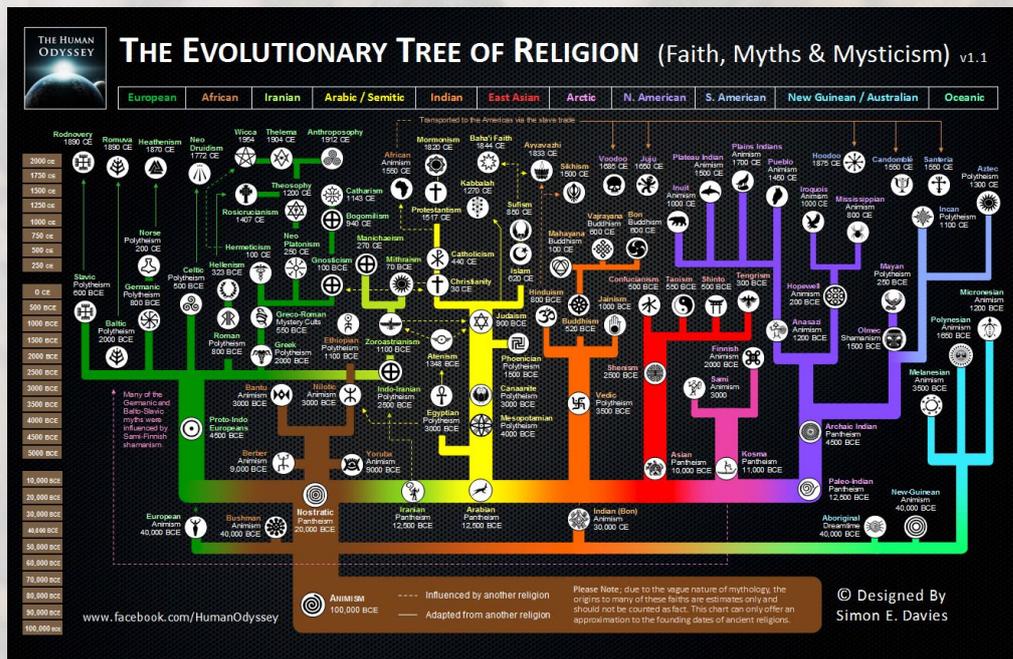

(1) The Evidence for Evolution of Religions from Animism, Shamanism and Ancestor Worship: Religions do display evolutionary relationships over time, due to the cross-infection of ideas, as illustrated in fig 146 and to natural variation, speciation and some forms of syncretic recombination. Buddhism, Jainism and Hinduism, in its many forms, all involve commonalities of world view and emergent movements such as Tantrism have overlapped these traditions. Likewise the Zoroastrian notion of cosmic renovation infected the Hebrew tradition to become Jewish apocalypticism and then the Christian version in the Gospels and Revelation. However evolutionary writers including Rossano (2010), Dunbar (2022) and from a more archaeological perspective Hayden (2003), consistently see the origins of religion in mystical and trance states associated with shamanism and animism, particularly given the vastly longer time scale of gatherer-hunter social evolution.

In fact, one can see that all animals that have evolved an awareness of their agency as biological organisms, including *Homo sapiens*, ARE animists, because their prime existential crises and fulfilment hinge around the mortal threats, and food and partnership opportunities other animals provide, with other existential crises caused by fire flood and storms featuring as forms of live environmental agency as well. It is only with the evolution of culture and human manufacture that we have come to the notions of creationist theism and our ideas of reality have become surrounded by machines and machine thinking to the exclusion of live agency, which is threatening to subsume us in AI.

Fig 145: The evolutionary tree of religion is rooted in animism (Simon Davies).

Brian Hayden (2003) in "A Prehistory of Religion: Shamans, Sorcerers and Saints" expresses it thus:

While it is fashionable to use psychological or social models (Durkheim 1915) to explain the origin of religion, these approaches are unsatisfactory for a number of reasons from an archaeological and ecological point of view.

First, the amount of time and effort invested in many religious activities such as the building of Stonehenge are far beyond what one would expect of any simple anxiety-reducing behavior, unless entire populations were extremely phobic. Moreover, high levels of anxiety do not accord with any ethnographers' observations that I am aware of. In fact, ethnographers sometimes remark on the surprising lack of concern that hunter-gatherers and horticulturalists display about the future.

Secondly developing an inherent tendency to enter into ecstatic or altered states of consciousness must have involved major transformations of the physical structure of the human brain. In ecological theory, such changes are incomprehensible unless they also confer advantageous survival benefits; that is, unless these changes are in some ways adaptive.

Third, it might be argued that the expansion of the brain's neocortex and especially the dominance of the left hemisphere (see *Music Is in the Hemispheres*, below) were adaptive because they made culture possible at the cost of suppressing functions of earlier parts of the brain. In this view, the function of religion is to reduce the stresses between these different parts of the brain. This explanation has a relatively narrow scope, however, accounting only for ritual behavior. In contrast, ecological explanations such as those to be discussed cover a much wider range of behavior, including sharing, alliances, and kinship. In addition, ecological explanations encompass unique types of human behavior that are difficult to understand under other paradigms. Such behaviors include the human reaction to rhythms and their link to rituals, the acceptance of new values presented while in ecstatic states, and the notion of higher principles or beings.

Robin Dunbar (2022) in "How Religion Evolved" clearly expresses this view (Riesz 2022):

At the emotional heart of religion, as Dunbar sees it, is something he calls "the mystical stance", which includes "a susceptibility to enter trance-like states", "belief in a transcendental (or spirit) world" and "a belief that we can call on hidden power(s) to help us". Though sophisticated systems of theology have obviously been built on these foundations, "beneath the surface veneer of doctrinal rectitude lurks an ancient foundation of pagan mystical religion". One of the key questions is how the original immersive or shamanic forms of religion develop into elaborate doctrinal religions.

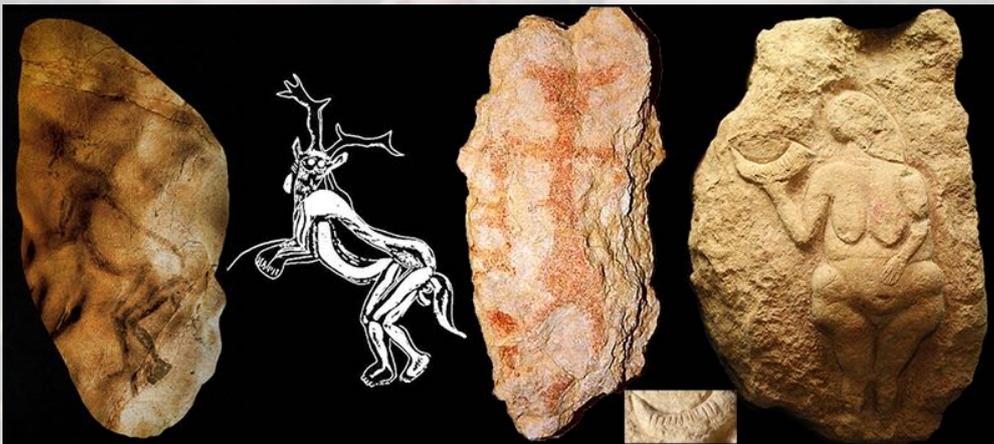

Fig 146: Left and Centre: Two ancient shamanic portraits cited by Rossano. Left: the 'sorceror' of Trois-Frères Cave (c 14000 BP). Centre: Fumane shaman with antlers (c 25500 BP). Right: The Venus of Laussel (c25000 BP) a representation of the Great Mother, with ochre smeared pubis holding and looking at a horn with 13 menstrual marks (13x28=364), representing the lunar bull and male fertility. Thus we see the patriarchal view of divinity as not arising in the sky God nor in human dominion over nature, but in the sheer spiritual wildness of nature that encompasses both the tiger and the thunderstorm. The shaman manifests the character of a therianthrope – an animal that transforms into a human and vice versa – the power animal, or apotheosis representing our unbounded spiritual nature, exemplified by the San /Kaggen and other trickster heroes, the humble werewolf, and even in an exploded apocalyptic form, by Yeshua and his miraculous apotheosis, Christ.

Nick Spencer's (2022) review elaborates:

Dunbar is clear that religious practices improve the individual's "fitness". "Active involvement in religion both makes you feel happier and provides you with a level of support that helps you cope." The second key urge takes us beyond this "functional" role. Humans are predisposed towards the transcendent. The "mystical stance" is widespread, ancient in origin, and "part of what it is to be human". Whether through trance states in early "shamanic" religions or less dramatic but still affecting encounters with music, art or nature, the sense of being part of something deeper and more profound than ourselves is near-universal. None of this means that such feelings are necessarily true. Dunbar is clear that doctrinal truth claims, such as about the nature of God or of creation, have played a relatively minor and recent role in the evolution of religion. Rather, it is simply that belief in a spiritual realm or in human purpose or destiny is very deeply ingrained in our nature. Dunbar is clear that the same religious urges that engender pro-social behaviour within the group can also provoke antisocial behaviour outside it — the more I bond with my co-religionists, the less I have in common with those of other faiths. And when religious identity is co-opted by the state, the result can be disastrous.

Matt Rossano (2010), in "Supernatural Selection" places this back to the first worldwide spread of modern humans:

At the same time of the worldwide spread of modern humans we see the first compelling evidence for the religious practices of shamanism, animism, and ancestor worship. Echoing the famous anthropologist Roy Rappaport, my view is that this is more than mere accident. Religion played a nontrivial role in the achievement of distinctively human society. ... Thus, where we observe greater ubiquity we can infer greater antiquity: An increasingly widespread trait is likely to be a more ancient one that possibly traces back to the origin of the species. Using this same logic, we can attempt to identify religion's "primitive" traits.

He discovers the foundations to be ancestor worship, shamanism, and animism, the belief in natural and animal spirits:

Using this approach, three traits emerge: ancestor worship, shamanism, and the animistic belief in natural and animal spirits. Each of these traits represents a "supernaturalizing" of social life—a way in which our ancestors expanded the social world to include a supernatural layer filled with ever-vigilant spiritual monitors.

He summarises his basis for these being the evolutionary source:

Ancestor worship: *is widespread across traditional religions in Africa, Asia, the Pacific Islands, and the South American tropics. In his survey of traditional African religions, missionary and religious scholar Geoffrey Parrinder states flatly, "All Africans believe in the ancestors, as ever-living and watchful." Half a world away, on the Solomon Islands, the same attitude persists among the Kwaio people, for whom daily interaction with ancestors is as routine as eating, drinking, and sleeping. Interacting with the ancestors, however, does not always happen within the context of recognizable rituals. Efe Pygmies regularly interact with ancestors in the forest and in dreams, but they engage in hardly anything that would look to us like worship.*

Shamanism: *The term "shaman" comes from the Tungus root saman, meaning "one who is excited or raised" or simply "to know." This reflects the fact that the shaman's function is to enter an altered state of consciousness wherein he or she connects with spiritual forces in order to gain knowledge or cure illness. The shaman, then, is a spiritual practitioner—a specialist whose job is to interact with the spiritual world.*

Animism: *The belief in a spiritual force pervading all of nature is common among hunter-gatherers. Powerful animal spirits play a prominent role in the art, myths, and religious beliefs of traditional people as culturally and geographically diverse as the Aborigines of Australia, the Inuits of the Arctic, the Ainu of northern Japan, the Bushmen of South Africa, the Jahai of Malaysia, and numerous native North and South American tribes. Animal spirits were also prominent among the great chiefdoms of pre-Columbian America (e.g., Aztecs, Toltecs, Incas) and the early great civilizations of the Old World (Egypt, Mesopotamia). There are some exceptions and variations. For example, while Aka Pygmies believe in animal spirits, neither Mbuti nor Baka Pygmies do. Instead, Baka Pygmies believe in anthropomorphized "game spirits," while the Mbuti see the entire forest as a living spirit.*

However Rossano, unlike Dunbar neglects the obvious centrality of the Great Mother, fully evident as far back as 35,000 years ago in the Aurignacian in the case of the Venus of Hohle Fels. Rianne Eisler (1987) in "The Chalice and the Blade" summarises the early evidence for the Great Mother:

It would seem only logical that the visible dimorphism, or difference in form, between the two halves of humanity had a profound effect on Paleolithic systems of belief. And it would seem equally logical that the fact that both human and animal life is generated from the female body and that, like the seasons and the moon, woman's body also goes through cycles led our ancestors to see the life-giving and sustaining powers of the world in female, rather than male, form. In sum, instead of being random and unconnected materials, the Paleolithic remains of female figurines, red ocher in burials, and vagina-shaped cowrie shells appear to be early manifestations of what was later to develop into a complex religion centering on the worship of a Mother Goddess as the source and regeneratrix of all forms of life. This Goddess worship, as James and other scholars note, survived well into historic times "in the composite figure of the Magna Mater of the Near East and the Greco-Roman world.

Rossano pinpoints the transition between these early imagistic processes and traditional doctrinal religions:

Anthropologist Harvey Whitehouse argues that religion exists in two modes: imagistic and doctrinal. The imagistic mode is characterized by infrequent, emotionally charged rituals that create the conditions for strong social bonding among participants. This mode encourages private reflection on emotionally arousing events. Its effects typically remain localized and personalized, not conducive to widespread transmission. By contrast, the doctrinal mode facilitates the efficient spread of religious beliefs across a broad population. It does this by stressing frequent, stylized rituals that encourage the rote storage of a common set of actions, stories, and teachings (e.g., the Catholic mass, where the story of Jesus' last meal is reenacted and his message of sacrifice is revisited). While the doctrinal mode is an efficient tool for transmission, it can also lose its force through tedium. Thus, both modes are believed necessary for a religion to remain vital: the imagistic providing the individual motivation to participate in religious activities, the doctrinal to establish a common set of ideals and behaviors. Whitehouse contends that the imagistic mode is historically more ancient, probably dating as far back as the "religious" cave art of the Upper Paleolithic. I agree, but I suggest that the ritual and emotional roots of the imagistic mode run far deeper than the Upper Paleolithic — to well before the African Interregnum (100000-60000). Conversely, the foundations for the doctrinal mode emerge much later.

This distinction between imagistic spirituality as expressed in diverse forms in the animism section and the doctrinal religion people tends to associate with religion and its social impacts also is the distinction between the source mysticism that underlies all religious inspiration that lies at the seeds of new religions and the prescriptive memes traditional religions apply to their populations to maintain theistic control over human beliefs and actions.

Robin Dunbar (2022) coincides with this evolutionary position:

The earliest forms of religion took the shape of a rather generalized belief in spirits or a form of being that sometimes occupied a transcendental world parallel to the physical one in which we live, but also might occupy the same physical space as we do. In some cases, these spirits had no particular interest in our world; in other cases, they were responsible for causing – or curing – the illnesses that we fall prey to. These older religions are religions of immersive experience, rather than religions of formal ritual with specialists who intercede on behalf of the laity. They are often (but not always) associated with trance states, usually induced by music and dance. In this, they share many underlying features with the mysticism that we find in all the doctrinal religions. By general consensus, mysticism involves direct ecstatic experience of the divine. It is a very personal form of ‘religion of experience’, a sense of immersion in the ineffable, the ‘oneness of being’ as the medieval Christian mystics described it. In its modern forms, these features tend to reflect the particular beliefs of the religion to which the mystic belongs. Mystics from the Christian, Sufi Islam and Sikh traditions will experience this as immersion in the oneness of God, whereas Buddhists experience it as immersion in the luminous universal mind. Sometimes these trance states (often described as ‘visions’) are spontaneous (as seems to have been the case with many historical Christian mystics like St Teresa of Ávila or the German Dominican friar Meister Eckhart); in other cases, trance may be brought on by group rituals, usually involving music (as in the trance dances of the San Bushmen) and sometimes assisted by plant-based psychotropic (or mind-altering) drugs (many South American tribes), or individually by meditative practices (as in the yogic tradition). Because the use of trance in one form or another is so widespread in these animist forms of religions, I refer to them collectively as ‘shamanic religions’, or ‘immersive religions’.

He then notes the transition to doctrinal religion:

At some point, there was a transition to a more formal kind of religion marked by regular places of worship, gods (who sometimes actively intervene in human affairs), religious specialists or priests (who intervene between the community and the gods, in some cases via trance-based rituals), more formal theologies, and moral codes that have divine origins – Moses receiving the tablets with the Ten Commandments directly from God on Mount Sinai, the Prophet Muhammed receiving the dictation of the Koran from God, Joseph Smith receiving the golden plates of the Book of Mormon. Most of these doctrinal religions also have origin stories, often associated with the revelatory experiences of a specific individual as founder – Zoroaster in the case of the Zoroastrians of ancient Persia; Siddhārtha Gautama for the Buddhists; Jesus Christ for Christians; the Prophet Muhammed for Islam; Guru Nanak for Sikhism. Because these religions typically have quite explicit theological doctrines, they are often known as doctrinal religions. They are also known as world religions because most of them now have very large followings spread over most of the planet (notwithstanding the fact that this is actually a very recent phenomenon). The important point to emphasize is that this sequence is not necessarily a process of replacement of one kind of religion by another. It is, rather, one of accretion – one form of religion (a doctrinal phase) being bolted onto the earlier (shamanic or animist) form.

Later, Dunbar pinpoints this to the rise of large urban cultures associated with agriculture and animal husbandry:

Six religious traits were mapped across thirty-three contemporary hunter-gatherer societies distributed across southern Africa, South and East Asia, Australia and the Americas, and then the ancestral states of these traits reconstructed statistically. The six traits were: animistic beliefs, shamanism, ancestor worship, belief in an afterlife, belief in local gods who keep to their own domain, and belief in High Gods who interfere in human affairs (Moralizing High Gods). The study found that animism is likely to have been the oldest of these traits, being present, uniquely, in all the cultures in the sample, despite their wide geographical distribution. On the other hand, belief in an afterlife is by no means universal and, along with shamanism and ancestor worship, appears to form a suite of traits that evolved together later. In contrast, belief in High Gods seemed to be completely divorced from all the other traits (very few hunter-gatherers actually believe in High Gods); instead, it seems to be a trait exclusively associated with the rise of agriculture and pastoralism (Peoples & Marlowe 2012, Peoples, Duda & Marlowe 2016).

He also reinforces mysticism and altered states as foundational to all forms of religious tradition (Guerra-Doce (2015):

*Mysticism has been a major component of all the major religions. By mysticism, I mean a feeling of divine transcendence that comes over an individual from time to time, sometimes spontaneously, sometimes as a result of deliberately engaging in ritualized activities. It is variously referred to as ecstasy or enthusiasm (from the Ancient Greek word *enthousiasmós*, meaning ‘possessed by god’). In its most developed forms, it usually involves a sense of drifting into a different plane of consciousness, of becoming so detached from the world of everyday experience as to no longer notice the sights and sounds of the physical world, a sense of losing track of time, of peacefulness – sometimes described in the mystical literature as the ‘stillness of the mind’. These are a susceptibility to enter trance-like states, a belief in the existence of a transcendental (or spirit) world, and a belief that we can call on hidden power(s) to help us. The mystical stance is the belief that we can experience this hidden essence directly only through our minds.*

The mystical stance seems to emerge out of two separate, but related psychological components. One is a need to believe in a spiritual dimension to human life. This may well derive from a deep-seated reluctance to believe that death really is death, the end of life and being. The other has to do with altered states of consciousness, both those induced by trance and those that arise from

accidents of experience (such as epileptic fits) or the use of mind-altering drugs. ... One survey of 488 ethnographic societies drawn from all continents concluded that no less than 90 per cent incorporated altered states of consciousness into their belief systems. ... The experience of trance also bears a close similarity to those that occur during near-death experiences. ... In many ways, the archetypal form of trance is the kind found among hunter-gatherers like the San peoples of Botswana and Namibia. The San use dance to trigger trance. Conventionally, it is the men who dance and the women who provide the musical accompaniment by clapping and singing. In most cases, the men dance in a circle until exhaustion sets in, triggering trance ().

In this process, Dunbar (2022) makes a very careful analysis of biological evolution:

Group selection, as the latter is known, requires the differential survival of whole groups and was often viewed as the explanation for altruism or population regulation: some animals don't breed in order to ensure that the population or species does not exhaust its food supply and go extinct. The problem is that there is no known genetic mechanism that would allow this: any species that behaved in this way would quickly find its altruism undermined by individuals that reproduced selfishly as fast as they could. This is not to say that group selection cannot work. It can, but it requires very high rates of group extinction and very low rates of migration between groups, and so far no study has found rates of group (or even culture) extinction that are anything like high enough to allow it to work. For this reason, biologists look with deep suspicion on any suggestion that benefits might accrue solely for the benefit of the group and against the interests of the individual.

The fact that religion can incur serious costs in terms of self-imposed pain, celibacy and even self-sacrifice has led some evolutionary psychologists and cognitive science of religion scholars to conclude that religion and religiosity cannot be adaptive, but must instead be the maladaptive by-product of traits or cognitive processes that evolved for other perfectly respectable biological purposes.

Animals do not live in groups because they like each other. They live in groups for the specific purpose of solving one or more of the components of fitness. ... In all these cases, the benefit arises only because the group exists, but its impact on fitness always accrues at the level of the individual, or even the gene. If the group does not provide a benefit for the individual, individuals will not put up with the inevitable costs of living in a group. Evolutionary biologists refer to this process as group-level (or group augmentation) selection, or more simply as mutualism. This is essentially the same process as that involved in symbioses, where two species live in close harmony with each other, thereby enhancing each other's survival chances.

He nevertheless takes a strongly affirmative position concerning the reality of cultural evolution:

Another important point to appreciate is that the function of a trait and its mode of inheritance are two separate, unrelated things. Any mechanism that allows a trait to be passed on from one individual to another, whether or not they are biologically related and share any genes, acts in a Darwinian fashion. Learning or cultural transmission is such a mechanism, and hence can be analysed using the same mathematics as is used to explore the evolution of genetically inherited traits. Culture is a Darwinian process, and cultural traits (or even entire cultures) evolve under selection, much as individuals and species do. Culture, however, can evolve both in ways that influence an individual's biological fitness and in ways that influence the fitness of a given cultural element within a purely cultural world. In theory, there is nothing evolutionarily implausible about a cultural phenomenon driving the genes of the bodies (or minds) that they parasitize to extinction – providing they can jump from one mind to the next (by cultural transmission) faster than they cause each body they inhabit to die.

This leads to some pessimistic views of the evolution of religion:

In general, evolutionary cognitive science of religion has adopted one of two views to explain how and why religion evolved. One is that religion is an unavoidable, and hence evolutionarily largely uninteresting, consequence of the way the human mind happens (or had) to be designed to support other evolutionarily more important functions. Religion is simply the cost that had to be paid in order to maximize evolutionary fitness. Alternatively, it might be an example of cultural evolution exploiting the way the human mind is designed so as to maximize cultural fitness despite the negative effect this might have on the fitness of the individuals whose minds are being parasitized. Both are, as we shall see in the next section, perfectly plausible explanations from a conventional Darwinian point of view.

And Dunbar is under no illusion that religions necessarily benefit the welfare of individuals, because of the dire consequences some religious groups or doctrines entertain, not just in the apocalyptic endings of Jim Jones with cyanide and David Koresh at Waco Texas in conflagration. More than 900 people died in the Jonestown massacre, in Guyana, including some 300 who were age 17 or under:

In the Christian tradition, the Adamite sect in late Roman Egypt insisted on complete nakedness during their services. Others, like the Russian Skoptsy (literally, 'castrates') sect, took matters even further, advocating breast and genital mutilation in women and the removal of both penis and testes in men (all performed with red-hot irons) so as to restore their bodies to the original pre-Fall condition of Adam and Eve in the Garden of Eden.

However, he is not interested in beliefs, but the overall sociobiological effects of religions on human groups:

Cognitive science of religion provides convincing explanations as to how human cognition underpins many aspects of religiosity and how these might have been exploited for these purposes. However, its focus is mainly on beliefs and so it overlooks some important

features of human religious experience that in many ways constitute the core fabric of religion – in particular, ritual and the role that religion plays in creating communities.

In this, he has a positive view, unlinked to any of the sometimes oppressive moral or doctrinal aspects of developed religions, citing the increased sense of belonging, community and mutual support religious groups offer, allowing larger social groups to form and maintain coherence, without precipitating internecine intracommunity violence and schism, noting for example the superior health, happiness and survival statistics of religious groups over non-affiliated.

This can apply both to individual benefits:

One widely articulated view is that religion provides a unifying framework for the world in which we live: it allows us to make sense of our world in a way that enables us to function effectively because we can control its more erratic behaviour. ... On top of that, we never know when we are likely to encounter any of the many more immediate threats to life – predators, plagues and pathogens, poisonous plants, and other humans (raiders).

A meta-analysis of forty-two studies, totalling nearly 126,000 subjects, found that active religious involvement increased the chances of being alive at follow-up by 26 per cent compared to those who never went to church, even when controlling for socio-demographic variables and existing health.

And to societal ones, involving both reputation and punishment of individuals:

In other words, a community that is invaded by even a small number of freeriders will very quickly either become dominated by selfish individuals or will fragment into small inward-looking subgroups. Part of the problem is that we are not naturally prosocial – something that is surely evident from the fact that both secular and religious authorities, not to mention family, constantly have to enjoin us to fulfil our obligations in this respect. ... Yet we are, nonetheless, willing to cooperate with, and be casually generous to, strangers. Neither economists nor evolutionary biologists have managed to find a convincing explanation for this, despite several decades of intensive experimental study. The best they have been able to do is suggest one of two possible mechanisms that seem to work: reputation and punishment. ... God is a particularly effective threat precisely because He sees everything even when the rest of us might not.

However he also invokes the carrot of commitment that religions also encourage, as a partial antidote to the stick of punishment. And with commitment also comes bonding and belonging. In this mix is a prominent aspect of risk avoidance and risk anxiety which the ordered world view of religions seeks to alleviate, which provides an explanation for both animism and doctrinal religions, with the proviso that in a basis sense the animistic view in gatherer-hunters societies, where risks predominate from natural agents, it has some scientific validity, lacking in later moral high Gods.

Essentially, this proposes that the animal mind is furnished with sensitivities to cues that allow it to detect salient phenomena that have direct effects on biological fitness (the ability to survive and reproduce successfully). For example, being able to infer that there is a predator approaching when hearing the snap of a twig in the forest is beneficial if you want to avoid falling prey to a predator or an enemy. Such mechanisms, they argue, are likely to be risk-averse because it is always better to mistakenly assume that there is a predator approaching than to mistakenly ignore the significance of such a cue when there really is a predator approaching (an example of Pascal's Wager). As a result, we humans are predisposed to attribute any phenomenon that we cannot readily explain to some mysterious being that we cannot see. There is no question that this effect is widely prevalent in humans: it is redolent in the way we attribute motivations to physical phenomena. We speak of the sea being angry or the sky lowering. On this view, then, religion is an inbuilt error in the biological system.

He also cites a careful, not excessive, degree of supernaturalness associated with religious belief:

Another classic example of this approach is the suggestion that gods are typically 'minimally counterintuitive', meaning that they have to be able to break the normal laws of everyday physics – but not by too much, otherwise they just become implausible.

Although he cites religions as enabling the growth of larger coherent societies, spanning the scales of bands 30-50, clans 100-200, tribes 1500 to whole urban civilisations, he is also interested in the ways religious groups nevertheless subdivide and result in schism over time because of the inherent difficulties of maintaining trust and belonging in larger social groups as religions grow. He sees this as also a product of the way doctrinal religions have evolved out of earlier and more immediate forms of animistic, shamanic and mystical rituals and practices that worked well for smaller groups of around 150 or so to whole populations of empires. This means that local churches are prone to invest in charismatic leaders, often criticising increasing elitism and moral corruption in the clerical hierarchy, to re-invoke the more immediate personal experiences of the underlying immanent form of religious experience that motivated doctrinal religions in the first place. Examples of this abound in the suppression of the Gnostics as heretics, the Reformation, the rise of Salafism in Islam and the diverse modern sects from the Quakers to Pentecostals as well as some of the terminal cults from Jonestown to Waco, Texas.

This has manifest implications concerning the war of fundamentalistic Christian religious groups against science over evolution since Darwin, as we shall see in the eighth section.

Complementing this evolutionary account, Thomas Römer in “The Invention of Gods” illustrates the cultural evolution of Yahweh as the Hebrew high god including his consortship with Asherah, in a transition from a syncretic polytheistic high god to an abstract ruler of the world acting in history.

The scientific historian of crisis, Jared Diamond (2021) points to the greatest power of religion in the civilised era of large agricultural societies being doctrines which enable large societies to remain coherent and dominant:

There are at least half a dozen powers of religious beliefs and among those half a dozen are political. The most straightforward of these political functions which arose only within the last five or six thousand years with the development of complicated political systems, one of those political functions is to justify obedience to kings and priests and emperors in a populist in a big society. In a small human society like the New Guinea societies where there are a few hundred people you know everybody by name there isn't any issue of dealing with strangers but so here you and I have met recently and in the in the in the last short time since we met each other neither you nor I has moved to kill each other, but in new guinea that would be unthinkable if I were at such a short distance from a stranger.

So you need something special to enable a large society where you encounter strangers to function religion plays an essential role. Religion offers a moral code which says how you're supposed to behave to everybody whether or not they're your fifth cross cousin or not there are like ten commandments every religion has which include thou shalt not kill – thou shall not kill a stranger but under circumstances thou shalt kill if you go to war with those people over there religion says yes you should kill those jerks because they are non-believers they don't have the true religion so religion in the last 5 000 years has acquired some new social political functions namely obey the king don't kill strangers but yes do kill strangers if they believe in the wrong religion. The power comes from the obedience that religion commands and the willingness to sacrifice oneself that religion commands. For example the world trade tower attack people with certain religious beliefs ended up killing 2993 people with other religious beliefs they sacrificed their lives there was enormous payoff in terms of the people killed with other religious beliefs.

He likewise discounts the idea that the universality of religion attests to its truth:

People who are believers would claim that the universality of religion speaks to the real existence of some supernatural phenomena or supernatural existence that everyone is sensing desiring and indeed in tune with. If you do not believe in such supernatural existence you still do have to explain the virtual ubiquity of religion. If one was going to draw conclusions and take comfort from the ubiquity of religion then you might expect it would be the ubiquity of one religion which is true but in fact every religion maintains all other religions to be untrue that already starts should make you start to be suspicious that that you can't make any arguments about truth from ubiquity. Some would claim that the you can because there is a commonality among those differences you can you can find the the lowest common denominator which in fact is a belief in a transcendence beyond the physicality of our own lives the ubiquity of religion seems to me a really weak defense of religion. There are other things that are that are ubiquitous the use of drugs.

Historian Yuval Noah Harari (2015) author of “Sapiens” (2014) in “Bananas in Heaven” likewise attributes the power of religions to their ability to invoke powerful fictitious “realities” through language:

What gives us this ability to do something no other animal can do? The answer is our imagination. Humans cooperate flexibly in large numbers because humans can create imagined realities together. All other animals use their communication system in order to describe reality. A chimpanzee can say, "Look there is a lion! Run away!" or "Look, there is a banana, let's take it!" Humans can use their language not only to describe reality but also to create new realities, to create fiction. A human can say: "Look there is a lion!" or "Look, there is a banana!" but the human can also say, "Look there is a God above the clouds, and if you don't do what they tell you to do, God will punish you." And if you believe this fictional story then you will do what you are told to do. And this is the secret behind large-scale human corporation. As long as everybody believes in the same fictional stories, everybody obeys the same laws, the same rules, and the same norms. And this is something that only humans can do.

(2) The Cosmological Claims of Religion: All religions lay claim to an ultimate cosmology of existence through their creation accounts. In terms of cosmology, Christianity for example, lays claim to an ultimate authority that is even applied retrospectively back from Yeshua's mission to the Biblical genesis giving him status of alpha and Omega. The Sabbatical Creation of Genesis is a quaint allegory, that passes the meme “efficiency” test with flying colours because it is so concise and endearing but is categorically wrong, both in the timing relationship of Earthly life to the solar system and to the order of the living species themselves. Once the notion of creation is implanted, the temptation to conceive of the universe in terms of creative design becomes almost impossible to overturn. Revelation likewise passes the “more motivating than reality” meme test by being so outrageously hyperbolic destroying the late planet Earth in apocalyptic conflagration leading to the newly created heavenly Jerusalem. This destructive eschatology is not only

incorrect, it is diabolically genocidal. It cements nature as completely expendable and leads to a complete disregard for natural or human survival in planetary crisis, to which religious dominion over nature has contributed.

While edge-of-chaos dynamics is pivotal to the way biogenesis, biological evolution and conscious experience, arising from, cosmological symmetry-breaking, world religions share a motif of the ultimate rule of order over chaos, which becomes a cosmic war against disorder, in the form of evil because, although each cosmology starts out pure, disorder creeps in, culminating in a destructive final renovation of the universe in the end of days. The Vedic cosmology ends in annihilation, in the Kali yuga. Buddhist cosmology similarly descends into the Saṃvartakalpa or "Eon of dissolution. In the western traditions we wind up with the Day of Judgment.

Such cosmologies thus invoke divine purity but introduce a cosmological war of order against chaos in a creeping dissolution perceived as primary evil. Just as Marduk the God of civic order is depicted as conquering Tiamat – the ancient Goddess of the Sea that is the symbol of the chaos of primordial creation, so later Near Eastern traditions from Zoroastrian, through Jewish, Christian and Islamic adopted the final solution of the end of days.

The Western notion of eschatological apocalypse originates from the Zoroastrian Frashokereti – a final renovation of the universe, when evil will be destroyed, and everything else will be then in perfect unity with God (Ahura Mazda).

Premises: (1) good will eventually prevail over evil; (2) creation was initially perfectly good, but was subsequently corrupted by evil; (3) the world will ultimately be restored to the perfection it had at the time of creation; (4) the "salvation for the individual depended on the sum of [that person's] thoughts, words and deeds, and there could be no intervention, whether compassionate or capricious, by any divine being to alter this." Thus, each human bears the responsibility for the fate of his own soul, and simultaneously shares in the responsibility for the fate of the world.

The accompanying story in the Bundahishn, runs as follows: At the end of the "third time" (the first being the age of creation, the second of mixture, and the third of separation), there will be a great battle between the forces of good (the yazatas) and those of evil (the daevas) in which the good will triumph. On earth, the Saoshyant – "one who brings benefit" – an eschatological saviour figure) will bring about a resurrection of the dead in the bodies they had before they died. This is followed by a last judgment through ordeal. The yazatas Airyaman and Atar will melt the metal in the hills and mountains, and the molten metal will then flow across the earth like a river. All mankind—both the living and the resurrected dead—will be required to wade through that river, but for the righteous (ashavan) it will seem to be a river of warm milk, while the wicked will be burned. The river will then flow down to hell, where it will annihilate Angra Mainyu and the last vestiges of wickedness in the universe. In later Zoroastrian texts, it is written that the molten metal will purify the wicked. The righteous will partake of parahaoma, which will confer immortality. Thereafter, humankind will live without food, without hunger or thirst, and without weapons (or possibility of bodily injury). The material substance of the bodies will be so light as to cast no shadow. All humanity will speak a single language and belong to a single nation without borders. All will share a single purpose and goal, joining with the divine for a perpetual exaltation of God's glory. While in the beginning there was one plant, one animal and one human, the variety that had since issued would remain forever. Similarly, the host of divinities brought into existence by Mazda continue to have distinct existences, "and there is no prophecy of their re-absorption into the Godhead.

Notice the ingestion of parahaoma, a form of the soma of the Aryans, with a mythical status as a founding sacramental drink associated with a number of plant species from ephedra to cannabis, just as Revelation says the tree of life provides monthly fruit and leaves for the healing of the nations.

"Thus saith the LORD to His anointed, to Cyrus, whose right hand I have holden, to subdue nations before him, and to loose the loins of kings; to open the doors before him, and that the gates may not be shut (Isaiah 45:1).

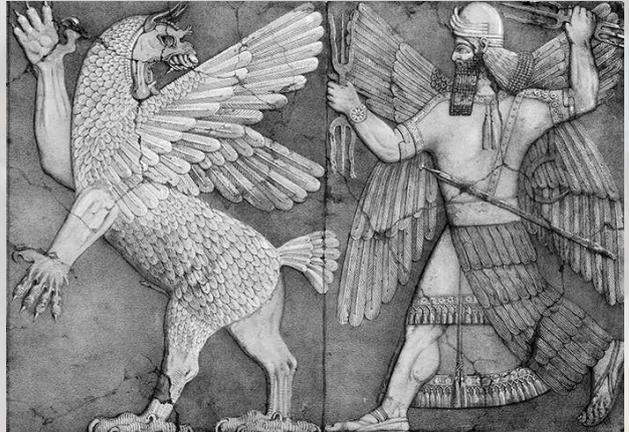

Christianity introduced a further element into eschatological apocalypse, in the form of the dying saviour later sacralised in Jesus as Christ in Pauline Hellenistic-Judaism. The dying-and-rising resurrection deity is a religious motif often cited from the religions of the ancient Near East, and traditions influenced by them include Biblical and Greco-Roman mythology and by extension Christianity. The concept was first proposed in comparative mythology by James Frazer's seminal *The Golden Bough* (1890). Frazer associated the motif with fertility rites surrounding the yearly cycle of vegetation. Frazer cited the examples of Osiris, Tammuz, Adonis and Attis, Dionysus and Jesus:

With Attis, Adonis or Thammuz, we begin to close about the Christian altar. Behind them, as behind the slave who was King of the Wood, there looms, scarcely named, the shadow of that other God, who as Son of Man ... died on the tree. And inescapably we are brought to conclude that Jesus the Christ acquired divinity by assuming the attributes of another deity (Bishop 1936).

In Pfeiderer's *Philosophy of Religion* (1878), he freely adopts a position of 'nature mythology':

The earliest action in the way of worship in the primitive history of mankind, was nothing but a dramatic repetition of the divine life seen in the processes of nature, with a view to taking part in it in a mutual intercourse of gods and men. The usages connected with the spring and autumn festivals in nature-religions everywhere show very plainly an effort to represent the coming and the departure of the deity of life and light, in such a manner that the changing fortunes of the deity may be repeated and experienced afresh in the imitative acts and emotions of their worshippers. Thus in Egypt was celebrated the complaint of Isis for Osiris, in Syria the marriage and the death of the sun-god Melcarth or Adonis, in Eleusis the search and lament for her daughter Core ... in Athens the death and resurrection of Dionysus.

Fig 147: Marduk and Tiamat. The war of order against chaos, light vs dark, good vs evil and male vs female. This is a cosmological fault, as the diversity and complexity of life and consciousness arises at the edge of chaos. The eschatological renovation entered Jewish and later Christian thought through the Edict of Restoration, of Cyrus II of Persia (c. 600–530 BC) a proclamation attested by a cylinder seal in which Cyrus authorised and encouraged the return of the Israelites to the Land of Israel following his conquest of the Neo-Babylonian Empire.

This association was reinforced by Pfeleiderer (1903):

The 'animistic' notion of the sacraments did not first make its way into Christianity in the post-apostolic time, but pervades the whole Pauline theology'. What Paul accomplished was to 'ethicize' the 'original enthusiasm' of the early Christians 'which in its original form was closely related to the orgiasm of Mysteries'. In so doing, Paul 'created for the growing Christian Church the elements of its ceremonial, without which no Church religion could arise or maintain itself' ... 'essentially the same myth lies at the origin of the mysteries' of Osiris, Adonis, Demeter and Persephone, and Dionysus, while 'nearly allied to these legends of the violent death of a god are those which tell of the voluntary descent of a god or hero into the underworld and his fortunate return', such as Tammuz.

Some of the premises have been debated by Smith (1990), who commented in his critique of Pfeleiderer:

In his last work devoted to the topic and published in 1905, Pfeleiderer more strongly insists on the parallels between Paul and the mysteries of the dying and rising gods, as well as Paul's creative genius in transforming them into an 'ethical' system, and makes an additional set of arguments. The use of these 'borrowings' was necessary to distinguish Christianity from Judaism. Its 'orgiastic' enthusiasm, now domesticated by Paul, is what freed early Christianity from the rigidities of 'national-legal' Judaism. When this domestication later failed, the 'dangerous one-sidedness' of Gnosticism resulted.

From Pfeleiderer's initial publications, although never without challenge, the interpretation, especially, of Pauline myth and ritual as being intrinsically related to the pattern of dying and rising gods, has persisted in some circles of New Testament scholarship. Thus R. Bultmann could continue to declare, in 1965, that Paul's understanding of baptism was grounded in the theology of the Hellenistic-Christian community: which understood this traditional initiation-sacrament on analogy with the initiation-sacraments of the mystery religions. The meaning of the latter is to impart to the initiates a share in the fate of the cult-deity who has suffered death and reawakened to life - such as Attis, Adonis, or Osiris.

But Smith claimed the dying God was irrelevant because it was seasonal, while Yeshua's mission was "once and for all":

The death of Jesus is further distinguished from the fate of all the mystery-deities by the fact that it happened once and for all , and is incapable of being repeated cultically; here we have an historical event, there IS a mythical drama.

For in that he died, he died unto sin once: but in that he liveth, he liveth unto God (Romans 6:10).

But this is a false criticism because it was clear that Yeshua's entire mission, as described in the gospels, is a once and for all mission of apocalypse, but the entire episode is played out as a single performance of a Dionysian tragedy, in the Greek fertility tradition, as Hugh Schonfield carefully documented in "The Passover Plot (1965) and is accounted in detail in the [Natty Dread](#) chapter. And in the Pauline Eucharist, Christ is reborn anew in every celebration of the Mass.

Regardless, in Christianity, whether expressed in Yeshua's own concepts and actions, or the additions of Paul and later gospel writers, we have the central notion of Jesus as the only begotten Son of God, whose sacrificial death in the crucifixion became a necessary atonement for the forgiveness of sins:

He said unto them, But whom say ye that I am? Peter answering said, The Christ of God. And he straitly charged them, and commanded them to tell no man that thing; Saying, The Son of man must suffer many things, and be rejected of the elders and chief priests and scribes, and be slain, and be raised the third day (Luke 9:20).

The synoptic mission account proceeds through a panoply of elements of fertility cult religions. John the Baptist had already had his head served up on a platter as trophy for Salome dancing Inanna's descent at Macherus in front of Herod's generals. Yeshua is then ministered unto out of their substance by the women of Galilee, performing Dionysian miracles, anointed to his doom by a woman alleged to be Magdalen, set at nought in a Roman Saturnalia and cries "Eloi, Eloi, lama sabachthani?" echoing Psalm 22 and the Canaanite cry of Mot to El, on the cross, looked on from far off by the women of Galilee, while cursing the daughters of Jerusalem, risen on the third day after harrowing hell and ascends to Abba the Father, becoming the only begotten Son of God, enshrined in the hybrid Godhead of the Trinity.

The sacrificial element appears to be a memetic device to create a Hellenistic religion out of Yeshua's apocalyptic mission, culminating in his death, devised 17 years later in the Pauline epistles, and elaborated 20 years later again in Mark, Luke and Matthew, so that we have little idea of how much of this is Yeshua's own tragic Dionysian Theatre and how much is Paul's Hellenistic revision using Yeshua, the apocalyptic preacher, as a cipher.

There is a glaring contrast between the apocalypse and sacrifice of the canonical gospels and the Gospel of Thomas, which has barely a hint of either, raising further questions over the authenticity of the canonical accounts. When the synoptics say Peter declares Yeshua is the Christ, in Thomas (13) Yeshua denies it: "I am not your master. Because you have drunk, you have become intoxicated from the bubbling spring which I have measured out." The entire apocalyptic expectation is brought into the gnostic present: (51) "His disciples said to him, "When will the repose of the dead come about, and when will the new world come?" He said to them, "What you look forward to has already come, but you do not recognise it." There are only hints of apocalypse, but there is no mention of Christ's returning in power: (79) "For there will be days when you will say, 'Blessed are the womb which has not conceived and the breasts which have not given milk.' " There is only one oblique reference to the sacrificial sacred marriage, whose conclusion is unclear: (61) "Two will rest on a bed: the one will die, and the other will live."

Fig 148: (Left) God blessing the Seventh day (Blake) (Right) Creation of Adam (Michelangelo). Although God is conceived of as incorporeal, omnipotent and transcendent, all conceptions of God are routed through human agency.

In effect, as in Matthew 25:31 and *Revelation*, Christ has taken over the role of Saoshyant and become the key administrator of justice, but to achieve this role has had to die a sacrificial death to the Father God, so that sins can be forgiven. In the Avestan source tradition there is no need for this homicide, which comes out of contrasting tradition of mortal sacrifice of the dying God. We thus have a hybrid apocalyptic cosmology founded on two inconsistent notions, the cosmic renovation where each being is free and responsible for their actions, and the resurrected saviour whose acknowledgement as Lord becomes the only remedy for the remission of sins, thus providing a fertility tradition short circuit to the purity of Frashokereti. There is no way that this can be validly presented as an actual cosmology of the universe in which we consciously exist and this means the notion of God it presents is at best a syncretic mythopoetic notion, and at worst a disingenuous contrivance to present Christ as the cosmic intercessor with God, in whom we must believe, while God has become sequestered in the background.

To make this more explicit, we need to examine the nature of God as conceived by religions. The notion of deity has arisen from animism, the world view where all natural phenomena are treated as living agency. The earliest such characters are trickster heroes such as the San peoples Kaggen, or mantis – a human-insect-bird therianthrope – or shape-shifter between animal and human form. It is only later that such deities became enshrined in religions as the many deities we know from Kali, Vishnu and Shiva, through Quetzalcoatl, the plumed serpent who rose from his own ashes and also had human form, to El, Asherah, Inanna, Enki, Tammuz, Zeus, Hera and Dionysus. YHWH is depicted as an abstract deity, but nevertheless has all-too-human emotional attributes. Ultimately such deities evolved into the

male creator deity of patriarchal monotheism and then to hybrid chimeric forms, such so the Trinity composed of Father, Son and Holy Ghost. Abba as the "Father" returns irreversibly to the anthropocentric mold, with Mary and the dying Jesus ubiquitous as graven images adorning Catholic altars.

Genesis confesses the 'Elohim are in human likeness in a mutual anthropocentric projection, thus typecasting God as a the Creator and Legislator as an anthropocentric projection of human manufacture and governance:

Let us make man in our image, after our likeness: So 'Elohim created man in 'their' own image, in the image of 'Elohim created he him; male and female created he them (Genesis 1).

The outright 'humanness' of God's personality is likewise manifested in God's palette of mammalian limbic emotions, from love and compassion, through patience, to jealousy and wrath. Because Christianity focuses almost exclusively on the personae of Yeshua and Christ, we gain most of our idea of the God of monotheism through the Old Testament.

In the Hebrew tradition, God's love is covenantal, even to the point of tempting the faithful to infanticide:

And it came to pass after these things, that God did tempt Abraham, and said unto him, Abraham: and he said, Behold, here I am. And he said, Take now thy son, thine only son Isaac, whom thou lovest, and get thee into the land of Moriah; and offer him there for a burnt offering upon one of the mountains which I will tell thee of. ... And Abraham stretched forth his hand, and took the knife to slay his son. And the angel of the LORD called unto him out of heaven, and said, Abraham, Abraham: and he said, Here am I. And he said, Lay not thine hand upon the lad, neither do thou any thing unto him: for now I know that thou fearest God, seeing thou hast not withheld thy son, thine only son from me.

The Psalms reverberate with Yahweh's protective love of His people:

How excellent is thy lovingkindness, O God! therefore the children of men put their trust under the shadow of thy wings (Ps 36:7).

Because thy lovingkindness is better than life, my lips shall praise thee (Ps 63:3).

But thou, O Lord, art a God full of compassion, and gracious, long suffering, and plenteous in mercy and truth (Ps 63:3).

But let all those that put their trust in thee rejoice: let them ever shout for joy, because thou defendest them: let them also that love thy name be joyful in thee. For thou, Lord, wilt bless the righteous; with favour wilt thou compass him as with a shield (Ps 5:11)

But this love is tempered by the covenant of faith:

And Solomon said, O Lord God of Israel, there is no God like thee in the heaven, nor in the earth; which keepest covenant, and shewest mercy unto thy servants, that walk before thee with all their hearts (2 Chron 6:14).

For the mountains shall depart, and the hills be removed; but my kindness shall not depart from thee, neither shall the covenant of my peace be removed, saith the Lord that hath mercy on thee (Isa 54:10).

Know therefore that the Lord thy God, he is God, the faithful God, which keepeth covenant and mercy with them that love him and keep his commandments to a thousand generations (Deut 7:9)

Who is a God like unto thee, that pardoneth iniquity, and passeth by the transgression of the remnant of his heritage? he retaineth not his anger for ever, because he delighteth in mercy (Micah 7:18).

The Lord thy God in the midst of thee is mighty; he will save, he will rejoice over thee with joy; he will rest in his love, he will joy over thee with singing (Zeph 3:17).

However, the jealousy of God is the most outstandingly prominent aspect of his personality in the scriptures:

But ye shall destroy their altars, break their images, and cut down their groves:

For thou shalt worship no other god: for the Lord, whose name is Jealous, is a jealous God: Lest thou make a covenant with the inhabitants of the land, and they go a woring after their gods. (Exodus 34:13)

And I will judge thee, as women that break wedlock and shed blood are judged; and I will give thee blood in fury and jealousy. (Ezekiel 16:38)

Ye shall not go after other gods, of the gods of the people which are round about you; (For the Lord thy God is a jealous God among you) lest the anger of the LORD thy God be kindled against thee, and destroy thee from off the face of the earth. (Deut 6:14)

However God's love leads to the supplicant bride Israel:

And I passed by you and I looked on you and behold, your time was the time of love. And I spread my skirt over you and I covered your nakedness. And I swore to you and I entered into a covenant with you and you became Mine. She is now washed, anointed, dressed, wrapped, covered, and adorned with silks, fine linen, embroidery, gold, and silver. And you were very beautiful and you advanced to regal estate. And your name went out among the nations, because of your beauty; for it was perfect, by My Splendor which I had set on you (Ezek. 16).

Regina Schwartz (1996) has cutting comment on this passage:

Ezekiel 16, the extended allegory of Israel as a whore, brings the relation between whores, exile, and monotheism (adultery, defiled land, and idolatry) into sharp focus. It is the story of a child being born and growing up wild and unloved in the field, and when she matures into puberty, of her being owned, sexually and materially, by Yahweh.

What is pivotal to understand here is that this zealous and jealous nature is exactly what was instituted by the forefathers, to ensure that their religion of Yahweh could keep itself distinct from the multitude of religions of the nations on all sides. It's purpose and the allegory of Israel as sacred bride and the allegory of Christ as the Bridegroom in its shadow is NOT the divine presence of God speaking, but the institution of a powerful patriarchal replicative meme designed to have maximally efficient social effect.

Religious believers might try to argue that this is just the flawed human description of God's inscrutable nature, but this is not a defence, because we are dealing with a God acting in history, so His actions and commands clearly declare His intended effects, for example at Jericho:

And the city shall be accursed, even it, and all that are therein, to the LORD: only Rahab the harlot shall live, she and all that are with her in the house, because she hid the messengers that we sent. ... And they burnt the city with fire, and all that was therein: only the silver, and the gold, and the vessels of brass and of iron, they put into the treasury of the house of the LORD (Joshua 6).

If we reject the notion that this is God's justice in favour of Joshua's human fallibility, the whole thesis fails including the ten commandments of Moses. But actually it is God's jealous curse of the religions of the nations operating here as it did through to the time of Josiah in fear of the Babylonian invasion:

[Josiah] began to purge Judah and Jerusalem from the high places, and the groves, and the carved images, and the molten images. And they brake down the altars of Baalim in his presence; and the images, that were on high above them, he cut down; and the groves, and the carved images, and the molten images, he brake in pieces, and made dust of them, and strowed it upon the graves of them that had sacrificed unto them. And he burnt the bones of the priests upon their altars (2 Chron 34 4-5).

And he brought out the grove (asherah) from the house of the Lord, without Jerusalem, unto the brook Kidron, and burned it and stamped it small to powder, and cast the powder thereof upon the graves of the children of the people. And he brake down the pavilions of the effeminate, which were in the house of the Lord, where the women wove hangings for the grove (2 Kings 23 3).

By contrast, the Christian expression of God's love is sacrificial, rather than covenantal. God's love is imputed indirectly because He sacrificed His only begotten Son to become the intermediary with whom we communicate:

But God commendeth his love toward us, in that, while we were yet sinners, Christ died for us (Rom. 5).

What shall we then say to these things? If God be for us, who can be against us? He that spared not his own Son, but delivered him up for us all, how shall he not with him also freely give us all things? (Rom. 8.)

But God, who is rich in mercy, for his great love wherewith he loved us, Even when we were dead in sins, hath quickened us together with Christ, (by grace ye are saved) (Eph. 2).

For God so loved the world, that he gave his only begotten Son, that whosoever believeth in him should not perish, but have everlasting life (John 3).

In this was manifested the love of God toward us, because that God sent his only begotten Son into the world, that we might live through him. Herein is love, not that we loved God, but that he loved us, and sent his Son to be the propitiation (sacrifice) for our sins (John 4).

For the Father himself loveth you, because ye have loved me, and have believed that I came out from God (John 16).

Centrally the covenantal aspect has been transferred from Yahweh to Yeshua as tangible intermediary:

He that hath my commandments, and keepeth them, he it is that loveth me: and he that loveth me shall be loved of my Father, and I will love him, and will manifest myself to him (John 14).

Finally we have the intervention of the Holy Ghost as a second intermediary, again leaving the Father remote, although Christians do pray to the Father, in the Holy Ghost, seeking the love and mercy of Christ:

And hope maketh not ashamed; because the love of God is shed abroad in our hearts by the Holy Ghost which is given unto us (Rom 5).

But ye, beloved, building up yourselves on your most holy faith, praying in the Holy Ghost, Keep yourselves in the love of God, looking for the mercy of our Lord Jesus Christ unto eternal life (Jude 20).

Both the Gospel of Thomas and the Synoptics do quote Yeshua as citing the three as one triad, although only the Holy Ghost deserves accusation of blasphemy for transgression:

Jesus said: He who blasphemes against the Father will be forgiven, and he who blasphemes against the Son will be forgiven; but he who blasphemes against the Holy Spirit will not be forgiven, either on earth or in heaven." (Thom 44)

However, we know the Christian God of the Trinity is not a cosmological manifestation but a contrivance. In the fourth century, Arianism taught that the Father existed prior to the Son who was not, by nature, God but rather a changeable creature who was granted the dignity of becoming "Son of God". In 325, the First Council of Nicaea adopted the Nicene Creed which described Christ as "God of God, Light of Light, very God of very God, begotten, not made, being of one substance with the Father", and the "Holy Ghost" as the one by which "was incarnate... of the Virgin Mary".

Therefore we come to terms with the fact that Christianity is saddled with an impossible cosmologically discordant idea of God, inconsistent with the original nature of the Zoroastrian renovation, forming a deceptive short-circuit to forgiveness by belief in Jesus as Lord and Saviour when he is returning as the avenging Lord in Revelation anyway. A critically efficient meme to outmanoeuvre the Hebrew tradition in favour of the Hellenistic view, that then swept through the pagan nations, who were already sympathetic to these ideas, through the agency of Paul establishing the rituals of a Hellenistic religion, founded on Yeshua's apocalyptic mission.

The Christianity of the New Testament is a creative combination of Jewish and Hellenistic traditions transformed into a tertium quid ('a third something'): that is, a reality related to two known things but transcending them both (Aune 1987).

Central to the entire Hellenistic emphasis is the nature of the Eucharist as the founding rite of the Christian religion. According to the Pauline epistles (1 Corinth 11:23–25) and the later gospels, the rite was instituted by Yeshua. During the Last Supper (Matt 26:26–28; Mark 14:22–24; Luke 22:17–20;) he commanded them to "do this in memory of me" while referring to the bread as "my body" and the cup of wine as "the blood of my covenant, which is poured out for many". Ignatius of Antioch (born c. 35 or 50, died between 98 and 117), one of the Apostolic Fathers, mentions the Eucharist as "the flesh of our Saviour Jesus Christ". Two forms are also cited in the first century Didache. In Catholicism, this is elaborated in the doctrine of transubstantiation the turning of the bread and wine into the soma and sangre of Christ. It is expressed in the teaching that Christ is risen from the dead and is alive, so that when the bread is changed into his body, not only his body is present, but Christ as a whole is present ("the body and blood, together with the soul and divinity"). The same holds when the wine is transubstantiated into the blood of Christ. In the Reformation Protestant churches rejected this doctrine or amended it to an undefined spiritual presence.

Although God is conceived of as being omnipotent, omniscient, omnipresent and omnibenevolent as well as having an eternal and necessary existence and is most often held to be incorporeal, related to conceptions of transcendence or immanence the supreme being, as world creator, and principal object of faith, He is invoked by the faithful as a person in a loving and yet supplicant relationship in the same form as a beneficent yet exacting human leader. Believers are thus conceiving of God in their own experience of relationships with others, regardless of His reality or actual nature and existence, or otherwise. In other words, the idea of God corporeal or otherwise is a human view of emotional and intellectual agency inspired through scriptural belief.

This is not to tell the whole story of divinity, because, as Rudolph Otto (1917) has made clear, these are but the rational dimensions of the Holy:

It is essential to every theistic conception of God, and most of all to the Christian, that it designates and precisely characterizes Deity by the attributes Spirit, Reason, Purpose, Good Will, Supreme Power, Unity, Selfhood. The nature of God is thus thought of by analogy with our human nature of reason and personality; only, whereas in ourselves we are aware of this as qualified by restriction and limitation, as applied to God the attributes we use are 'completed', i.e. thought as absolute and unqualified. Now all these

attributes constitute clear and definite concepts: they can be grasped by the intellect; they can be analysed by thought; they even admit of definition. An object that can thus be thought conceptually may be termed rational.

In coming to understand the Holy of Holies that underlies the religious quest and is deeply chthonic to its superficial memetic nature as a process of social control, Otto ranges through terms such as sacred to find the invent a special term to stand for 'the holy' minus its moral factor or 'moment', and, as we can now add, minus its 'rational' aspect altogether, which he comes to term the numinous which we shall explore later in the context of the brain.

It will be our endeavour to suggest this unnamed Something to the reader as far as we may, so that he may himself feel it. There is no religion in which it does not live as the real innermost core, and without it no religion would be worthy of the name. ... For this purpose I adopt a word coined from the Latin numen. Omen has given us ominous, and there is no reason why from numen we should not similarly form a word 'numinous'. I shall speak then of a unique 'numinous' category of value and of a definitely 'numinous' state of mind.

(3) Religion is an Avowedly Memetic Process: Religions are profoundly memetic and are custom designed by their forefathers to have precisely the powerful influence of religious culture over individual interests, personal liberty and even human survival that the memetic detractors express. Notwithstanding their mystical and numinous basis, these are also vehemently opposed by organised religion as disturbing the dominant order. Religion inextricably has two complementary and contradictory natures. It lays claim incorrectly to cosmological ascendancy but at the same time is constructed as an intensely captivating meme system in which the believer comes to serve the interests of the religious complex and its social following, rather than human survival or individual benefit, or true spiritual illumination. This is why *religio* is to 'bind' as in the Roman fasces. This means Dawkins' warning is not to be set aside. To achieve any long-term viable human culture, and ensure the future of the human species, it is essential that the memetic control of religion over human culture and the human mind is liberated from bondage.

Patriarchal Monotheism

1. **Security:** God is the generator of cosmological order, out of and triumphal over, chaos, providing ultimate security.
2. **Power:** God is omniscient, omnipotent Lord, creator and legislator. This is cosmological autocracy, in human image.
3. **Belief:** Love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind, and with all thy strength.
4. **Compulsion:** To turn aside from, or reject the religious path is atheism, blasphemy, heresy or apostasy.
5. **Hierarchy:** Woman and nature are supplicant to man, as man is to God.
6. **Eternal morality:** Moral judgment is rewarded and punished in the end of days by eternal torment or salvation.
7. **Conflict:** This casts order and chaos, good and evil, light and dark as in a state of eternal war, destroying fecundity.

This is a dominant memetic system, enticing by its ultimate security and the notion that loving God is reciprocated by God's love, along with the ultimate incentive of eternal life resolving all existential uncertainties, but it's dark underbelly is the ultimate fear of God's wrath, the condemnation of all human beings as original sinners, the social and physical punishments of one's flaws being discovered, either by one's religious neighbours or by God himself leading to dire earthly punishment or eternal torment.

The culturally memetic influence of religion on human evolution, through patriarchal dominance of reproductive choice is profoundly expressed in the amplified reproduction rates of Islam, and following it Christianity, to fulfil their utopian aims of world dominance is expressed in their heightened birth rates over the population as whole (Pew Res).

(4) Natural versus Memetic Morality: We have the problem of morality as an evolved cooperative good versus an oppressive imperative. The sociobiological view of morality is that it is a win-win adaption through group selection which also favours individual survival. Curry et al. (2019) express this in extremely eloquent terms:

Life begins when molecules start making copies of themselves. These 'replicators' are 'selfish' in the technical sense that they promote their own replication (Dawkins, 1976/2006). They can promote their replication at the expense of other replicators. These competitive interactions have a winner and a loser; one's gain is another's loss; they are zero-sum games (Maynard Smith, 1982; Von Neumann & Morgenstern, 1944). Replicators can also replicate in concert with other replicators (Dawkins, 1998). These cooperative interactions can have two winners; they are win-win situations; they are non-zero-sum games. Natural selection can favour genes for cooperation – that is, genes for evolutionarily-stable phenotypic strategies designed to achieve superior equilibria in non-zero-sum

interactions – and has done throughout the history of life. Natural selection for genes that employ cooperative strategies has driven several ‘major transitions’ in the evolution of life on Earth, including the formation of cells, chromosomes and multicellular organisms (Maynard Smith & Szathmáry, 1995). Natural selection has also favoured genes for cooperation between individuals, in a wide variety of species (Dugatkin, 1997), including humans. Humans descend from a long line of social primates; they have spent 50 million years living in social groups (Shultz, Opie, & Atkinson, 2011), and two million years making a living as intensely collaborative hunter-gatherers (Tooby & DeVore, 1987). This has equipped humans with a range of biological – including psychological – adaptations for cooperation. These adaptations can be seen as natural selection’s ‘attempts’ to solve the problems of cooperation. More recently, improvisational intelligence and cultural transmission (Boyd, Richerson, & Henrich, 2011; Pinker, 2010) have made it possible for humans to attempt to improve upon natural selection’s solutions by inventing evolutionarily-novel solutions – ‘tools and rules’ – for further bolstering cooperation (Binmore, 1994a, 1994b; Hammerstein, 2003; Nagel, 1991; Popper, 1945). Together, these biological and cultural mechanisms provide the motivation for social, cooperative and altruistic behaviour; and they provide the criteria by which individuals evaluate the behaviour of others. According to MAC, it is precisely these solutions to problems of cooperation – this collection of instincts, intuitions, inventions and institutions – that constitute human morality (Curry, 2005, 2016).

Laland (2017) notes that socially organised societies becomes dominant over competitors, including by force of arms, following Richerson and Henrich (2012):

(1) societies with an organized army are more likely to win conflicts than those without, (2) city-states with division of labor and occupational specializations would tend to out-compete those without these innovations, (3) agricultural communities that have devised irrigation systems would flourish more readily than others, and (4) societies with religious doctrines that stabilize within-group cooperative activities will thrive at the expense of those with no gods to help ensure compliance.

Yet he still presents the religious spectre as basically a benign cooperative process, in which the docile members of a religiously conforming society will out-survive their more rebellious independently-minded colleagues without any reference to the kinds of draconian punishments conservative and religious societies go to the lengths to exercise:

Theoretical analyses suggest that humans should be particularly adept at recognizing, representing, and adopting the local norms of their society, as well as notice, condemn, and punish violations of those norms. For instance, moral norms could plausibly have generated natural selection acting on human genes to favor cooperative tendencies. Individuals who are more inclined to conform to norms would find it “easier to enter larger norm-bound societies and to abide by the rules, than individuals lacking this tendency. These more “docile” individuals would be at an advantage, to the extent that they would be better placed to benefit from the society’s technologies and less vulnerable to exclusion or punishment. In turn, a population of more docile individuals could then permit the cultural evolution of more sophisticated and effective norms, and allow groups to maintain more reliable cooperation. A similar mechanism could have favored a tendency of individuals to feel shame or guilt when they violate a social norm.

Haidt & Graham (2007) present theoretical and empirical reasons for believing that there are five psychological moral systems (MF) that provide the foundations for the world’s many moralities:

The five foundations are [1] psychological preparations for detecting and reacting emotionally to issues related to harm/care, [2] fairness/reciprocity, [3] ingroup/loyalty, [4] authority/respect, and [5] purity/sanctity. Political liberals have moral intuitions primarily based upon the first two foundations, and therefore misunderstand the moral motivations of political conservatives, who generally rely upon all five foundations.

They base this on the notion that conservative societies have moral intuitions not recognised by social liberals:

On this definition of morality, conservative opposition to social justice programs appears to be immoral, and has been explained as a product of various non-moral processes such as system justification or social dominance orientation. In this article we argue that, from an anthropological perspective, the moral domain is usually much broader, encompassing many more aspects of social life and valuing institutions as much or more than individuals.

As noted above, Curry et al. (2019) define Morality-as-Cooperation (MAC) as the theory that morality is a collection of biological and cultural solutions to the problems of cooperation recurrent in human social life and have expressed it in the following seven principles:

(1) Allocation of resources to kin (Family Values), (2) Coordination to mutual advantage (Group Loyalty), (3) Social exchange (Reciprocity), (4,5) Contests between Hawks (Heroism) & Doves (Deference) in which agents fairly indicate how far they are prepared to pursue a conflict, (6) Division (Fairness) divide the resource proportionately by bargaining power and (7) Possession (Property Rights) deferring to prior possession.

Curry et al. tested MAC’s predictions by developing the Morality-as-Cooperation Questionnaire (MAC-Q), and comparing its psychometric properties to those of the Moral Foundations Questionnaire (MFQ). They found that over four studies, the results supported the MAC-Q’s seven-factor model of morality, but not the MFQ’s five-factor model. Thus MAC emerges as the best available compass with which to explore the moral landscape.

The upshot of this research is that morality has a valid basis as a win-win that enhances both group and individual survival, on a sociobiological basis where natural selection is paramount, but does not include prescriptive culturally originating religious imperatives of an oppressive nature that invoke dire penalties when they are not observed.

Effectively the five factor MF is presenting conservative morality, which goes further than natural morality of MAC to enforce cooperation by 'altruistic' punishment as practiced widely by prescriptive religions.

Rossano (2010) describes this process as "getting people in line":

I argued that there are two ways for groups to establish and maintain intra- group cooperativeness that extends beyond the boundaries of kin selection, reciprocity, and indirect reciprocity: (1) by motivating people to follow group-based social norms, and (2) and by motivating them to punish those who don't follow social norms. One of the chief sources of this motivation is social scrutiny—the idea that we are being watched and judged by others. Given the close-knit nature of the hunter-gatherer groups from which we evolved, the notion of being constantly watched and evaluated was a familiar one. Experimental work shows that we are hypersensitive to the cues that suggest public observation of our behavior. Furthermore, this same work shows that we are naturally hypervigilant against freeloaders and cheaters who threaten group cohesion and that we have effective means of bringing them into line.

Religious doctrines exploit hypervigilance as actively enforced memes, both by constructive inducement as virtues and destructive moral punishment as sins, in ways that are far more encompassing and punitive than mere social disapproval.

(5) Religious Enforcement of Homicidal Violence: this brings us to the fallacy that religion is just a way of enticing people to cooperate by pro-social incentives. When the crunch comes, religious edicts, laws and punishments are among the most severe and unforgiving. Dismemberment for theft, stoning for adultery, and death for apostasy. While Islam today still displays these homicidal features in full iconic form, none of the patriarchal religions can consider themselves free of these diabolical practices in their long term history. I will address just a few violently homicidal examples that have particularly punished women, to make the situation clear.

Genocide at Medina and Femicide at Mecca

At first Muhammad had lived in peace with the people of Mecca, whose environs such as Taif had shrines to the Goddesses al-Uzza, Manat and al-Lat and for whom the Kaaba was a sacred site for all religious pilgrims and included astral and Christian figures. But when he decided that his verses accepting the three goddesses as intermediaries were a heresy spawned by satanic influence, and began to preach a more firebrand monotheism, this offended the sensibilities of the Quraysh of Mecca and he ended up having to escape to Medina with a small band of followers. There was a large Jewish community at Medina occupying an entire sector of the walled oasis settlement. Many Jews had settled in Arabia from the time of the Roman diaspora. However Muhammad found his new Arab religion, cast in the model of the Jewish heritage, was not respected by the Jews of Medina. Ostensibly, in response to this perceived insult, Muhammad turned the direction of prayer from Jerusalem to Mecca.

The situation soured and finally turned to genocide when the Quraysh of Mecca, angered by his disruptive influence, laid siege to Medina. The plight in the oasis became desperate. Not knowing which side would eventually win, the Qurayzah Jews sent a party to parley with the Quraysh to try to preserve themselves from being overrun by one side or the other and some of them were overheard swearing allegiance. But then in a superstitious misjudgment, the Quraysh deserted the siege when a severe desert storm struck the region. In the aftermath a Muslim friend of the Jews drew his finger over his throat to warn them of their impending fate:

According to Karen Armstrong's "Muhammad" (1991 206), fearing the Jews might have opened their gates to the enemy, Muhammad appointed a mortally wounded fighter Sa'd ibn Mu'adh who was carried to the Qurayzah village on a litter, as judge over their fates:

Sa'd judged that all the 700 men should be killed, their wives and children sold into slavery and their property divided among the Muslims. Muhammad cried aloud: "You have judged according to the ruling of Allah above the seven skies!" The next day Muhammad ordered a trench to be dug in the souk of Medina. Some individuals were spared at the request of the Muslims, but the rest were tied together in groups and beheaded; their bodies were thrown into the trench.

It is probably impossible for us to dissociate this story from Nazi atrocities and it will inevitably alienate many people irrevocably from Muhammad. But Western scholars like Maxime Rodinson and W. Montgomery Watt argue that it is not correct to judge the incident by twentieth-century standards.

But the problems are profound: (1) Appointing a mortally wounded man as judge is prejudicial. (2) This was an unmitigated genocide because the Jews never actually betrayed the Muslims and never did open their gates, or the story would have been entirely different. (3) In the 21st century these genocidal standards are still legitimised and applied by Muslims today and Muhammad extolled as a divine prophet in an age where genocide on this scale is a crime against humanity. There was no excuse and no valid rationalisation for this slaughter, and later Muslim history up to the taking of Mecca demonstrates that this killing proved to be unnecessary gratuitous violence for which history needs to judge this tradition.

Ending the period of religious tolerance that had made Mecca a divine pilgrimage destination, Muhammad smashed all the icons in the Ka'aba, leaving only the portraits of Jesus and Mary and ironically, the vagina-like meteoric Black Stone, the most sacrosanct symbol of the old religion. Likewise the images of al-Uzza and Manat and a year later also those of al-Lat at Taif, were destroyed, although the people there initially resisted and raised an army leading to an indecisive siege. Although Muhammad issued an amnesty to those who accepted his rule, a list of prominent opponents were summarily executed. Within two and a half years, Muhammad would pass away.

Nawal el Sadaawi in "The Hidden Face of Eve" notes the effect on women who opposed Muhammad's rule:

Sarah was a famous slave singer who aimed her barbed words against the Moslems. She was among those whom Mahomet ordered to be executed on the day of his victorious entry into Mecca. In the region of El Nagir, it was recounted that some women had rejoiced when the Prophet died and Abu Bake, the first of the Caliphs, ordered their hands and feet to be cut off. Thus women who dared to give voice to their protest or opposition could be exposed to cruel punishment. Their hands might be cut off, or their teeth pulled out, or their tongues torn from their mouths. This last form of punishment was usually reserved for those who were singers. It was said of these women that they used to dye their hands with henna, brazenly display the seductions of their beauty, and beat time with their fingers on tambourines and drums in defiance of God, and in derision towards the rights of God and his Prophet. It was therefore necessary to cut off their hands and tear out their tongues.

Muhammad was particularly unforgiving to anyone who ridiculed him or his Quranic verses. According to al-Tabari's *Alseera Al Nabawiya* (2:463) Muhammad explicitly ordered the murder of Om Kerfa (Mother of Kerfa), one of the most revered Meccan matriarchs who was torn in half by camels at the age of 90 for writing poetry ridiculing him:

She is Fatima daughter of Rabia son of Badir son of Amru al Fazari. Mother of Kerfa married a prince of the tribe of Hathifa and bore for him 13 children the first of whom was Kerfa by whom she is surnamed. All her children became leaders of their tribes. She was the dearest of all Arabs, and an example of honor and pride to them.. It was said if two tribes fought and Mother of Kerfa sent her scholl on a spear that was displayed to both parties, then they would reconcile out of respect for her. She used to annoy the prophet with her poetry so in the sixth year of the Hijra he sent Zaid son of Haritha on a military expedition to kill her in the most heinous of ways. For he tied her legs with ropes and tied each of the ropes to a camel so that she was split in two. She was an old woman when this happened and her head was severed as proof to all that she had died.

Code of Hammurabi

Religious invocations prescribing death for adultery are NOT divinely ordained. In the Code of Hammurabi (c1755-1750 BCE), a cited precursor to Mosaic law, adultery was punished with the death of both parties by drowning, but if the husband was willing to pardon his wife, the king might intervene to pardon the paramour. The law is much fairer in terms of exonerating accused females. Although the stele features an image in relief of Hammurabi with Shamash, the Babylonian sun god and god of justice, this is a secular law ordained by a ruler rather than a religious prophet.

CH 129 *If a man's wife be caught with another man, both shall be tied and thrown into the water, but the husband may pardon his wife and the king his slaves.*

CH 130 *If a man violate the wife of another man, who has never known a man, and still lives in her father's house, and sleep with her and be surprised, this man shall be put to death, but the wife is blameless.*

CH 155 *If a man have betrothed a bride to his son and his son have known her, and if he (the father) afterward lie in her bosom and they take him, they shall bind that man and throw him in the water.*

Deuteronomic Stoning for Adultery

Deut 22:20 *But if this thing be true, and the tokens of virginity be not found for the damsel: Then they shall bring out the damsel to the door of her father's house, and the men of her city shall stone her with stones that she die.*

Deut 22:22 *If a man be found lying with a woman married to an husband, then they shall both of them die, both the man that lay with the woman, and the woman: so shalt thou put away evil from Israel. If a damsel that is a virgin be betrothed unto an husband, and a man find her in the city, and lie with her; Then ye shall bring them both out unto the gate of that city, and ye shall stone them with stones that they die; the damsel, because she cried not, being in the city; and the man, because he hath humbled his neighbour's wife: so thou shalt put away evil from among you.*

Multiple other religious crimes, from apostasy and blasphemy to homosexuality and being an unruly son were also punished by stoning, except that, in later times, the caveats became so stringent that it virtually never occurred.

In the period prior to early Christianity, particularly in the Mishnah, doubts were growing in Jewish society about the effectiveness of capital punishment in general (and stoning in particular) in acting as a useful deterrent. Subsequently, its use was dissuaded by the central legislators. The Mishnah states:

A Sanhedrin that puts a man to death once in seven years is called destructive. Rabbi Eliezer ben Azariah says that this extends to a Sanhedrin that puts a man to death even once in seventy years. Rabbi Akiba and Rabbi Tarfon say: Had we been in the Sanhedrin none would ever have been put to death. Rabban Simeon ben Gamaliel says: they would have multiplied shedders of blood in Israel.

In the following centuries the leading Jewish sages imposed so many restrictions on the implementation of capital punishment as to make it de facto illegal.

Islamic Stoning for Adultery

The outstanding difference with Islam is that these practices continue to be religiously sanctioned. Four Hadith below show that Muhammad used the Deuteronomic punishment claimed to be for Jewish offenders to instil stoning for adultery as an Islamic punishment, centuries after the practise had been effectively discontinued in Judaism.

Hadith Stoning for adultery al-Bukhari 2:23:413 *Narrated 'Abdullah bin 'Umar: The Jew brought to the Prophet a man and a woman from amongst them who have committed (adultery) illegal sexual intercourse. He ordered both of them to be stoned (to death), near the place of offering the funeral prayers beside the mosque."*

Hadith Stoning for adultery al-Bukhari 4:56:829 *Narrated 'Abdullah bin 'Umar: The Jews came to Allah's Apostle and told him that a man and a woman from amongst them had committed illegal sexual intercourse. Allah's Apostle said to them, "What do you find in the Torah (old Testament) about the legal punishment of Ar-Rajm (stoning)?" They replied, (But) we announce their crime and lash them." Abdullah bin Salam said, "You are telling a lie; Torah contains the order of Rajm." They brought and opened the Torah and one of them solaced his hand on the Verse of Rajm and read the verses preceding and following it. Abdullah bin Salam said to him, "Lift your hand." When he lifted his hand, the Verse of Rajm was written there. They said, "Muhammad has told the truth; the Torah has the Verse of Rajm. The Prophet then gave the order that both of them should be stoned to death. ('Abdullah bin 'Umar said, "I saw the man leaning over the woman to shelter her from the stones."*

Hadith Stoning for adultery al-Bukhari 6.:60:79 *Narrated 'Abdullah bin Umar: The Jews brought to the Prophet a man and a woman from among them who had committed illegal sexual intercourse. The Prophet said to them, "How do you usually punish the one amongst you who has committed illegal sexual intercourse?" They replied, "We blacken their faces with coal and beat them," He said, "Don't you find the order of Ar-Rajm (i.e. stoning to death) in the Torah?" They replied, "We do not find anything in it." 'Abdullah bin Salam (after hearing this conversation) said to them. "You have told a lie! Bring here the Torah and recite it if you are truthful." (So the Jews brought the Torah). And the religious teacher who was teaching it to them, put his hand over the Verse of Ar-Rajm and started reading what was written above and below the place hidden with his hand, but he did not read the Verse of Ar-Rajm. 'Abdullah bin Salam removed his (i.e. the teacher's) hand from the Verse of Ar-Rajm and said, "What is this?" So when the Jews saw that Verse, they said, "This is the Verse of Ar-Rajm." So the Prophet ordered the two adulterers to be stoned to death, and they were stoned to death near the place where biers used to be placed near the Mosque. I saw her companion (i.e. the adulterer) bowing over her so as to protect her from the stones.*

The prescription in Sharia is stoning a woman to death for adultery submerged to her neck so only her head shows:

The penalty for adultery under Article 83 of the penal code, called the Law of Hodoud is flogging (100 lashes of the whip) for unmarried male and female offenders. Married offenders may be punished by stoning regardless of their gender, but the method laid down for a man involves his burial up to his waist, and for a woman up to her neck (article 102). The law provides that if a person who is to be stoned manages to escape, he or she will be allowed to go free. Since it is easier for a man to escape, this

discrimination literally becomes a matter of life and death. Article 104 provides that the stones should not be so large that a person dies after being hit with two of them, nor so small as to be defined as pebbles, but must cause severe injury. This makes it clear that the purpose of stoning is to inflict grievous pain on the victim, in a process leading to his or her slow death.

"In Muslim law the punishment of lapidation is only inflicted for adultery. Under Jewish law idolaters or bearers of false witness were also stoned. It is founded not upon the Qu'ran where the only punishment Sura 24:2 is one hundred stripes but upon the traditions where Muhammad is related to have said 'Verily God hath ordained for a man and a woman not married to one hundred lashes and expulsion from their home town for one year, and for a man and a woman having been married one hundred lashes and stoning'." When a woman is to be stoned, a hole or excavation should be dug to receive her as deep as her wallet ... The purpose of the hole is to conserve 'decency' for the female. Neither boulders nor pebbles may be used, so that death is neither mercifully quick nor endlessly prolonged" (Hughes - Dictionary of Islam).

Islamic Death for Apostasy

Hadith Death for Apostasy al-Bukhari 4:52:260 Narrated Ikrima: Ali burnt some people and this news reached Ibn 'Abbas, who said, "Had I been in his place I would not have burnt them, as the Prophet said, 'Don't punish (anybody) with Allah's Punishment.' No doubt, I would have killed them, for the Prophet said, 'If somebody (a Muslim) discards his religion, kill him.'"

The prescription in Sharia for Apostasy is death:

Apostasy in Islam is commonly defined as the abandonment of Islam by a Muslim, in thought, word, or through deed. It includes not only explicit renunciations of the Islamic faith by converting to another religion or abandoning religion altogether, but also blasphemy or heresy, through any action or utterance which implies unbelief, including those who deny a "fundamental tenet or creed" of Islam. While classical Islamic jurisprudence calls for the death penalty of those who refuse to repent of apostasy from Islam, the definition of this act and whether and how it should be punished, are disputed among Islamic scholars and strongly opposed by Muslim and Non-Muslim supporters of the universal human right to freedom of faith. According to classical Islamic law, an apostate can only be killed if there are two just Muslim eyewitnesses of the apostasy or if the apostate self confesses, according to some schools, both conditions are required. Jurists allowed flexibility in the application of the death penalty, allowing judges to interpret the apostasy law in different ways, [sometimes, they leniently interpreted it and at other times, they strictly interpreted it.

As of 2014, there were eight Muslim-majority countries where apostasy from Islam was punishable by death, and another thirteen where there were penal or civil penalties such as jail, fines or loss of child custody. From 1985 to 2006, only four individuals were officially executed for apostasy from Islam and unrelated political crimes by governments, but apostates have suffered from other legal punishments as well as extra-judicial punishments which have been inflicted upon them by vigilantes—imprisonment, the annulment of their marriages, the loss of their rights of inheritance and the loss of custody of their children. Mainly, the loss of life has resulted from killings which have been perpetrated by "takfiri" insurgents (ISIL, the GIA and the Taliban).

This is not to exonerate other religions, or to focus unjustified blame on Islam. Christianity has been plagued by centuries of religious bloodshed, fomented by obsessive martyrdoms, violent Crusades, religious wars, and centuries of Inquisition seeking to root out heretics from witches, through gnostics, to reformationists and mystics such as Marguerite Porete. All religions from, Buddhism through Hinduism to Zoroastrianism are marked with the blood of homicidal violence. The Bhagavad Gita, for example, is a spiritual treatise set in the context of holy war.

It is estimated that the witch hunts resulted in 70,000 to 100,000 deaths but others have suggested a much higher figure. During the Crusade against the Cathars and Albigenses, after the siege of Beziers alone, 20,000 were summarily executed on the spot. In 1209, a crusade from Pope Innocent III began against the Cathars. Both Cathars and Catholics were besieged by an army of the Church within the walls of Beziers. On the day of the feast of Mary Magdalen they killed their viscount in the church dedicated to her name and were in turn horrendously punished on the same day for repeating the Albigensian heresy that she was Christ's concubine. When the city fell, the commanding general was asked who to slaughter: heretics, his men assumed, must surely be separated from believers.

Their leader's reply was simple: "Kill them all," he said, "the Lord will know his own". *Our forces spared neither rank nor sex nor age. About twenty thousand people lost their lives at the point of the sword. The destruction of the enemy was on an enormous scale. The entire city was plundered and put to the torch. Thus did divine vengeance vent its wondrous rage.*

The situation was similar in Carcassone: *After discussion, our men entered the town of Carcassonne with the cross in front. When the church had been restored they placed the Lord's cross on top of the tower ... for it was Christ who had captured the town and it was right that his banner should take precedence. ... The venerable abbot of Vaux-de-Cernay went to a great number of heretics who had gathered in one of the houses wishing to convert them to better things, but they all said with one voice 'Why are you preaching to us? We don't want your faith We deny the church of Rome. You are wasting your time. Neither life nor death can turn us from the beliefs we hold.' He then went to see the women gathered in another building but the female heretics were more obstinate and difficult in every way. Simon de Montfort first urged the heretics to convert, but having no success, he dragged them out of the*

castle. A huge fire was kindled and they were all thrown into it. It was not hard for our men to throw them in, for they were so obstinate in their wickedness that they threw themselves in. Only three women escaped, whom a noble lady snatched from the flames and restored to the Holy Church.

Fig 149:(Left) The Gnostic 'heretics' being led out of Carcassone to be burned alive for apostasy 1209. (Right) Auto de Fe in the execution of Anne Hendriks in Amsterdam 1571⁵⁰ Jan Luyken.

This is also reflected in the tragic execution of Marguerite Porete, the first to die in the auto da fe in Paris:

The Mirror of Simple Souls is an early 14th-century work of Christian mysticism by Marguerite Porete (1996, 1999) dealing with the workings of Divine Love. Written originally in Old French when Latin was the prescribed language for religious literature, it explores in poetry and prose the seven stages of 'annihilation' the Soul goes through on its path to Oneness with God through Love. Enormously popular when written, it fell foul of the Church authorities, who, detecting elements of the antinomian Heresy of the Free Spirit in its vision, denounced it as "full of errors and heresies", burnt existing copies, banned its circulation, and tried and executed Porete in the first Auto da Fé in Paris in April 1310. Marguerite remained silent throughout her trial, with a plain refusal to elaborate, explain nor deny her teachings. Marguerite went to the stake in total silence and endured her firey end in silence. Those watching were moved to tears.

Love in this book layeth to souls the touches of his divine works privily hid under dark speech, so that they should taste the deeper draughts of his love and drink. — 15th-century English translator's prologue

(6) Theology, Neurotheology and Religious Psychology

Theology is described as the systematic study of the nature of the divine and of religious belief. Revelation pertains to the acceptance of God, gods, or deities, as not only transcendent or above the natural world, but also willing and able to interact with the natural world and to reveal themselves to humankind. This in its very definition as assuming the entity it is attempting to describe and setting up a stark division between an assumed transcendent divinity, palpable monotheistic and a flawed natural world comprising the diversity of life.

The term Theology derives from the Greek *theologia* (θεολογία), *theos* (Θεός, 'god') and *logia* (λογία, 'utterances, sayings, oracles') – relating to Greek *logos* (λόγος, 'word, discourse, account, reasoning'). Greek *theologia* was used with the meaning 'discourse on God' around 380 BC by Plato in *The Republic*. Aristotle divided theoretical philosophy

⁵⁰ Anneken Hendriks was an Anabaptist of Friesland, living in Amsterdam. Through treachery she was taken prisoner by the city officials. Because she held fast to her faith, she was severely tortured on 27 October 1571, with the intent of learning from her the names of other Mennonites. But even this ill treatment could not make her recant, and consequently she was put to death on the town square (Dam) on 10 November 1571. The execution took place in an unusually cruel manner. Anneken was tied to a ladder; her mouth was filled with gunpowder, and in this condition she was carried from the city hall to the ignited stake and thrown into the flames. She was fifty-three years old and an ordinary woman who could neither read nor write. In her sentence she was condemned because "she was married according to Mennonite custom, and at night in a country house." The *Martyrs Mirror* records that there is a song concerning her, but gives no further information, apparently meaning the song found in the Dutch hymn book *Veelder-hande Liedekens* (1569), which begins "Ick moet nu gaen verclaren, Watter t'Amsterdam is geschiet" (I must now declare to you, What took place at Amsterdam).

into mathematike, physike, and theologike, with the latter corresponding roughly to metaphysics. Latin writer Varro (116–27 BC) distinguished three forms of such discourse: 1. mythical, concerning the myths of the Greek gods; 2. rational, philosophical analysis of the gods and of cosmology; and 3. civil, concerning the rites and duties of public religious observance. In scholastic Latin sources, the term came to denote the rational study of the doctrines of the Christian religion. Christian theology as the study of Christian belief and practice concentrates primarily upon the canonical scriptures and Christian tradition. In Jewish theology, the historical absence of political authority has meant that most theological reflection has happened within the context of the Jewish community and synagogue, including through rabbinical discussion of Jewish law and Midrash (rabbinic biblical commentaries).

Theology considers whether the divine exists in some form, such as in physical, supernatural, mental, or social realities, and what evidence for and about it may be found via personal spiritual experiences or historical records of such experiences as documented by others. The central problem with Theology is that it is centred on doctrine, as the rational, linguistic component, driving moral coercion and prescriptive belief. That's counter-empirical to a violation fault. A distinction can be made between theology, which is seen as involving some level of commitment to the claims of the religious tradition being studied, and religious studies, which are not tied to any religious tradition and are normally neutral or secular.

Outside monotheism the status of theology is less explicitly defined. Within Hindu philosophy, there is a tradition of philosophical speculation on the nature of the universe, of God (Brahman, Paramatma, and/or Bhagavan in some schools) and of the ātman (soul). Vaishnava theology is involved in classifying and organising the manifestations of thousands of gods and their aspects. Buddhism, which is non-theistic focuses on philosophy rather than theology. In Japan, the term theology (shingaku) has been ascribed to animistic Shinto since the Edo period in Mano Tokitsuna's Kokon shingaku ruihen ('categorised compilation of ancient theology').

Whether or not reasoned discussion about the divine is possible has long been a point of contention, beginning in the time of earlier polytheistic and state deities of Ancient Greece. Protagoras, in fifth century BC, who is reputed to have been exiled from Athens because of his agnosticism about the existence of the gods, said that "Concerning the gods I cannot know either that they exist or that they do not exist, or what form they might have, for there is much to prevent one's knowing: the obscurity of the subject and the shortness of man's life."

Baron d'Holbach (1772), in *Le Bon sens*, labeled theology "a continual insult to human reason". Lord Bolingbroke wrote in Section IV of his *Essays on Human Knowledge*, "*Theology is a science that may justly be compared to the Box of Pandora. Many good things lie uppermost in it; but many evil lie under them, and scatter plagues and desolation throughout the world.*" Thomas Paine wrote in *The Age of Reason* (1794): "*The study of theology, as it stands in Christian churches, is the study of nothing; it is founded on nothing; it rests on no principles; it proceeds by no authorities; it has no data; it can demonstrate nothing; and it admits of no conclusion. Not anything can be studied as a science, without our being in possession of the principles upon which it is founded; and as this is the case with Christian theology, it is therefore the study of nothing.*"

Ludwig Feuerbach in *The Essence of Christianity* (1841), for which he was banned from teaching in Germany, said that theology was a "web of contradictions and delusions". The American satirist Mark Twain remarked in his essay "The Lowest Animal": "*Man is the only animal that loves his neighbor as himself and cuts his throat if his theology isn't straight. ... The higher animals have no religion. And we are told that they are going to be left out in the Hereafter. I wonder why? It seems questionable taste.*"

A. J. Ayer sought to show in his essay "Critique of Ethics and Theology" that all statements about the divine are nonsensical and any divine-attribute is unprovable: "*It is now generally admitted, at any rate by philosophers, that the existence of a being having the attributes which define the god of any non-animistic religion cannot be demonstratively proved. ... All utterances about the nature of God are nonsensical.*" Richard Dawkins in an article in *The Independent* (1993) said: "*I have never heard any theologian ever say anything of the smallest use, anything that was not either platitudinously obvious or downright false.*"

Religious Psychology Psychology of religion consists of the application of psychological methods and interpretive frameworks to the diverse contents of religious traditions as well as to both religious and irreligious individuals. Psychologists of religion pursue three major projects: 1. systematic description, especially of religious contents, attitudes, experiences, and expressions. 2. explanation of the origins of religion, both in the history of the human race

and in individual lives, taking into account a diversity of influences. 3. mapping out the consequences of religious attitudes and conduct, both for the individual and for society at large.

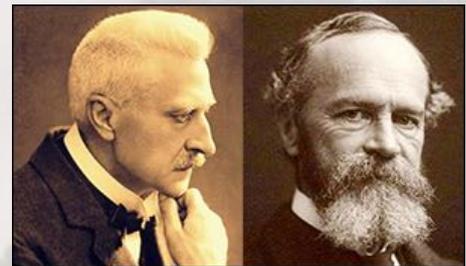

Hegel (1770–1831) described all systems of religion, philosophy, and social science as expressions of the basic urge of consciousness to learn about itself and its surroundings, and record its findings and hypotheses. Freud spoke of religion as an illusion – "a fantasy structure from which a man must be set free if he is to grow to maturity," viewing the idea of God as being a version of the father image, and religious belief as at bottom infantile and neurotic. Authoritarian religion, Freud believed, is dysfunctional and alienates man from himself. By contrast, Jung postulated, in addition to the personal unconscious, the collective unconscious, the repository of human experience and which contains "archetypes" (images that are universal and recur regardless of culture). The irruption of these images from the unconscious into the realm of consciousness he viewed as the basis of religious experience and artistic creativity.

The psychology of religion first arose as a self-conscious discipline in the late 19th century, but all three of these tasks have a history going back many centuries. In the 1890s, a "new psychology" emerged in European and American universities which coincided with the establishment of many new psychology laboratories and the appointment of faculty in psychology, James (1890). New psychology's novelty was encapsulated by its distinction from philosophy (philosophy of mind in particular) and theology, and its emphasis on the laboratory-based experimental method.

American psychologist and philosopher William James (1842–1910) is regarded by most psychologists of religion as the founder of the field. James distinguished between institutional religion and personal religion. Institutional religion refers to the religious group or organisation and plays an important part in a society's culture. Personal religion, in which the individual has mystical experience, can be experienced regardless of the culture.

Fig 149b: Rudolph Otto and William James

The Varieties of Religious Experience comprises his edited Gifford Lectures on natural theology, concerning the psychological study of individual private religious experiences and mysticism, and used a range of examples to identify commonalities in religious experiences across traditions. Soon after its publication, Varieties entered the Western canon of psychology and philosophy and has remained in print for over a century.

In the Varieties, James explicitly excludes from his study both theology and religious institutions, choosing to limit his study to direct and immediate religious experiences, which he regarded as the more interesting object of study. His chapters span the religions of healthy mindedness versus the sick soul, the divided self, conversion, saintliness and mysticism. James outlines four markers of mystical experience:

Ineffable: the experience is incapable of being described and must be directly experienced to be understood.

Noetic: the experience is understood to be a state of knowledge through which divine truths can be learned.

Transient: the experience is of limited duration.

Passivity: the subject of the experience is passive, unable to control the arrival and departure of the experience.

Moon, Kuza & Desai (2018) note the formative influence of his nitrous oxide experiences on his entire view of religious experience:

In 1874, William James wrote a celebratory review in the Atlantic Monthly of Benjamin Paul Blood's pamphlet The Anaesthetic Revelation and the Gist of Philosophy. He was captivated by the idea that "the Secret of Being" might be accessible with nitrous oxide not just by the academic intellectual but also by the ordinary man. Later, in his essay "On Some Hegelisms" (1882), James described his own experience with nitrous oxide as one characterized by an exhilarating sense of metaphysical awakening. Upon inhalation, he was able to understand first the glory and then the insufficiency of Hegelian thought. For James, the use of nitrous oxide ultimately served a key role in elucidating some of the most central ideas of his life: (1) the value of religion and (2) the universe as pluralistic (as opposed to absolutist, constant, eternal), driven by chance, experience, and change.

He enlarged on this in the Varieties p 373:

Nitrous oxide and ether, especially nitrous oxide, when sufficiently diluted with air, stimulate the mystical consciousness in an extraordinary degree. Depth beyond depth of truth seems revealed to the inhaler. This truth fades out, however, or escapes, at the moment of coming to; and if any words remain over in which it seemed to clothe itself, they prove to be the veriest nonsense. Nevertheless, the sense of a profound meaning having been there persists; and I know more than one person who is persuaded that in the nitrous oxide trance we have a genuine metaphysical revelation.

*Some years ago I myself made some observations on this aspect of nitrous oxide intoxication, and reported them in print. One conclusion was forced upon my mind at that time, and my impression of its truth has ever since remained unshaken. It is that our normal waking consciousness, rational consciousness as we call it, is but one special type of consciousness, whilst all about it, parted from it by the filmiest of screens, there lie potential forms of consciousness entirely different. We may go through life without suspecting their existence; but apply the requisite stimulus, and at a touch they are there in all their completeness, definite types of mentality which probably somewhere have their field of application and adaptation. No account of the universe in its totality can be final which leaves these other forms of consciousness quite disregarded. How to regard them is the question,—for they are so discontinuous with ordinary consciousness. Yet they may determine attitudes though they cannot furnish formulas, and open a region though they fail to give a map. At any rate, they forbid a premature closing of our accounts with reality. Looking back on my own experiences, they all converge towards a kind of insight to which I cannot help ascribing some metaphysical significance. The keynote of it is invariably a reconciliation. It is as if the opposites of the world, whose contradictoriness and conflict make all our difficulties and troubles, were melted into unity. Not only do they, as contrasted species, belong to one and the same genus, but one of the species, the nobler and better one, is itself the genus, and so soaks up and absorbs its opposite into itself. This is a dark saying, I know, when thus expressed in terms of common logic, but I cannot wholly escape from its authority. I feel as if it must mean something, something like what the Hegelian philosophy means, if one could only lay hold of it more clearly. **Those who have ears to hear, let them hear; to me the living sense of its reality only comes in the artificial mystic state of mind.***

James further comments: *I just now spoke of friends who believe in the anæsthetic revelation. For them too it is a monistic insight, in which the other – in its various forms appears absorbed into the One.*

"Into this pervading genius," writes one of them, "we pass, forgetting and forgotten, and thenceforth each is all, in God. There is no higher, no deeper, no other, than the life in which we are founded. 'The One remains, the many change and pass;' and each and every one of us is the One that remains.... This is the ultimatum. ... As sure as being—whence is all our care – so sure is content, beyond duality, antithesis, or trouble, where I have triumphed in a solitude that God is not above."

This has the genuine religious mystic ring!

Rudolf Otto (1869–1937), was a German Protestant theologian and scholar of comparative religion. His fascination with non-Christian religions was awakened during an extended trip from 1911 to 1912 through North Africa, Palestine, British India, China, Japan, and the United States. His first book, *Naturalism and Religion* (1904) divides the world ontologically into the mental and the physical, reflecting Cartesian dualism. He argues consciousness cannot be explained in terms of physical or neural processes, and also accords it epistemological primacy by arguing all knowledge of the physical world is mediated by personal experience. On the other hand, he disagrees with Descartes' characterisation of the mental as a rational realm, positing that rationality is built upon a non-rational intuitive realm.

In "The Idea of the Holy", Rudolph Otto (1917) writes that while the concept of "the holy" is often used to convey moral perfection – and does entail this – it contains another distinct element, beyond the ethical sphere, for which he coined the term numinous based on the Latin word *numen* ("divine power"). Otto explained the numinous an experience or feeling which is not based on reason or sensory stimulation and represents the "wholly other" – a "*non-rational, non-sensory experience or feeling whose primary and immediate object is outside the self.*" It is a mystery (*mysterium tremendum*) that is both fascinating (*fascinans*) and terrifying at the same time. A mystery that causes trembling and fascination, attempting to explain that inexpressible and perhaps supernatural emotional reaction of wonder drawing us to seemingly ordinary and/or religious experiences of grace. This sense of emotional wonder appears evident at the root of all religious experiences. Through this emotional wonder, we suspend our rational mind for non-rational possibilities.

This mental state "presents itself as ganz Andere, wholly other, a condition absolutely sui generis and incomparable whereby the human being finds himself utterly abashed." It cannot be defined in terms of other concepts or experiences. The subject must therefore be "guided and led on by consideration and discussion of the matter through the ways of his own mind, until he reaches the point at which 'the numinous' in him perforce begins to stir... In other words, our X cannot, strictly speaking, be taught, it can only be evoked, awakened in the mind." Wynn (2022) notes: *The Idea of the Holy falls within a paradigm in the philosophy of emotion in which emotions are seen as including an element of perception with intrinsic epistemic value that is neither mediated by thoughts, nor simply a response to physiological factors. Otto therefore understands religious experience as having mind-independent phenomenological content rather than being an internal response to belief in a divine reality.*

Neurotheology: The Brain on Religion, Spirituality and Mysticism The neuroscience of religion, also known as neurotheology and as spiritual neuroscience, attempts to explain religious experience and behaviour in neuroscientific

terms. Aldous Huxley used the term neurotheology for the first time in the utopian novel *Island*, in the context of psychedelics. It is the study of correlations of neural phenomena with subjective experiences of spirituality and hypotheses to explain these phenomena. This contrasts with the psychology of religion which studies mental, rather than neural states. Proponents say there is a neurological and evolutionary basis for subjective experiences traditionally categorised as spiritual or religious. From the religious perspective, concerns have been raised that the study of practices such as meditation does not necessarily extrapolate to the broader array of religious and spiritual phenomena (Begley 2001). Newberg's (2017) "Principles of Neurotheology" provides a scientific overview.

In "The Varieties of Spiritual Experience", Yaden & Newberg (2022) have produced a sequel to James' "Varieties of Religious Experience", in which the diversity of spiritual experiences are explored in a modern neuroscience context. These varieties encompass chapters on: (a) Numinous Experiences: Encountering divinity, (b) Revelatory experiences: Voices, visions, and epiphanies, (c) Synchronicity Experiences: "Everything happens for a reason", (d) Mystical Experiences: Unity and ego-dissolution, (e) Aesthetic Experiences: Awe and the sublime and (f) Paranormal Experiences: Ghosts, angels, and other entities.

Grewal (2012) reinforces the differing tendencies towards religious belief in intuition of the divine and away from belief in god in rational analytic discourse:

Shenhav, Rand and Greene (2011) show that people who have a tendency to rely on their intuition are more likely to believe in God. They also showed that encouraging people to think intuitively increased people's belief in God. Building on these findings, Gervais & Norenzayan (2012) found that encouraging people to think analytically reduced their tendency to believe in God. Together these findings suggest that belief may at least partly stem from our thinking styles. ... Gervais and Norenzayan's research is based on the idea that we possess two different ways of thinking that are distinct yet related. System 1 thinking relies on intuitive feelings, hunches, shortcuts and other rules-of-thumb while System 2 is based on on analytic thinking and tends to be slower and require more effort. Solving logical and analytical problems may require that we override our System 1 thinking processes in order to engage System 2.

The notions of both God and Vedantic primordial cosmic consciousness appear to simply be aspects of a more ancient intuitive "animistic" type 1 thinking as opposed to type 2 "analytical" thinking. This suggests both God and cosmic consciousness are latecomers in the evolution of the universe, as a product of humans as higher organisms, thinking of the universe as permeated and driven by subjectively conscious agents, as a working intuitive rule of thumb, for survival, without it necessarily making overall analytic sense, particularly when extrapolated onto the entire universe.

The idea of an innate religious propensity in evolution for the good is not so much about transformative mystical states, as the blessings of religious security, for example that conservative morality or the love of God is an innate or evolved 'instinct'. But, while we have found evidence for natural morality in humans, conservative morality presents rather as as a superimposed meme. As we have seen with Marguerite Porete, the mystical people are often cast wearing sackcloth and ashes, or being burned at the stake for their visions. Both the conformist patterns of religious belief and the diverse mystical experience of transcendence have been explored in brain studies. But the propensity discovered scientifically in the brain is that both meditative and psychedelic states are associated with quietening of the default mode network and the relaxing of identity-defining dynamics leading to integrated states of consciousness rooted in first person mystical experience.

The nature of subjective conscious volition over the world around us and its implications is our central existential dilemma because we gain our entire knowledge of the world through our subjective experiences of it. This is the central existential dilemma that animism has always encompassed, and which its offspring in religion and religion's backroom "soul" in spirituality⁵¹, seek to reveal. Scientific consciousness research opens the abyss of subjective experience, as the most outstanding unresolved scientific problem in the universe and that is what mystical and visionary propensity is actually about, which both lies at the foundation of religion but is diametrically opposite to it.

⁵¹ *Spiritualitas* L. from *spiritus* n. which means 'the breath of life', also psyche, or soul. Traditionally, spirituality referred to a religious process of re-formation which "aims to recover the original shape of man", oriented at "the image of God" as exemplified by the founders and sacred texts of the religions of the world and within early Christianity to refer to a life oriented toward the Holy Spirit and broadened during the Late Middle Ages to include mental aspects of life. In modern times, the term broadened to refer to a wider range of experience, including esoteric and religious traditions. Modern usages refer to a subjective experience of a sacred dimension and the "deepest values and meanings by which people live", often in a context separate from organised religious institutions. It may involve belief in a supernatural realm beyond the ordinarily observable world, personal growth, a quest for ultimate or sacred meaning, religious experience, or an encounter with one's "inner dimension".

There is also a pervasive belief in the idea that all spiritual paths lead to one deeper reality, as expressed in the perennial philosophy – a perspective in philosophy and spirituality that views all of the world's religious traditions as sharing a single, metaphysical truth or origin from which all esoteric and exoteric knowledge and doctrine has grown (Huxley 1946). Perennialism has its roots in the Renaissance interest in neo-Platonism and its idea of the One, from which all existence emanates, e.g. to integrate Hermeticism with Greek and Jewish-Christian thought. Ultimately this idea comes down to direct first person mystical experience, contemplative, meditative or entheogenic as the ultimate chthonic and illuminating groundswell of numinous reality, unbound from traditional religious assumptions.

Religion raises a serious dilemma for spirituality as a pursuit, because most of its perspective is underpinned by assumptions arising from existing religious viewpoints – memes which we now perceive to have a potentially distorting parasitic influence on the nature of spiritual and mystical experiences, even when these are in the first person. Notions, from God as creator, or legislator, to traditional notions of universal consciousness such as Brahman, all carry type-casting interpretations of spiritual identity. It is one thing to experience forms of transcendence and describe them metaphorically as experiences in terms of notions like Brahman, but it is another thing to a priori declare to third parties that they are evidential facts. They can be empirically verified by mutual affirmation of first person subjective experiences between people in mystical states discovering a commonality, just as the Huichol do experiencing the *nierika* on the peyote hunt. One of the great advantages of entheogenic experience is that it does not have to come with any pre-conceived spiritual assumptions although it is frequently associated with spiritual movements. To have any real potential to understand the nature of consciousness deep in the well of non-ordinary experience, it is absolutely necessary for the spiritually inclined to cleanse themselves of all 'parasitic' memes, such as assumptions about the nature of God or divinity, if they hope to experience genuine *moksha*, or *samadhi*.

In fact discarding memes is central to meditative practices promoting ego loss and is integral to the entheogenic effects of psychedelics. Anil Seth (2019) has argued that all perception is a form of controlled predictive hallucination evoked by the conscious brain. Dreams fall even more clearly into this category as well as claims about waking entheogenic visions, for which the term hallucinogen is a synonym of psychedelic. This implies that all religious beliefs in God are robust conceptual hallucinations reinforced by memes of affirmative belief, which are thus not physically or cosmologically real.

Erasing personal history is a technique advocated by Carlos Castaneda (1968), who also sees man's idea of God as a robust transfixing hallucination, that stymies the vision quest, while spirit is an ally to be enticed and commanded in the vision quest's pursuit:

Warriors know that the assemblage point is the place where perception is assembled within the structure of the luminous cocoon; the assemblage point is the crucial feature of human beings as luminous entities. Warriors know that they must train themselves to do two transcendental things: first, to conceive of the assemblage point, and second, to make that assemblage point move. Warriors know that their assemblage points become dislodged from their original positions through confrontations with the naqal. Warriors know that man's idea of God is one of the most sturdy aspects of the human inventory which binds the assemblage point to its original position. The spirit is an abstract which warriors know without words or thoughts, yet without the slightest desire to understand it, warriors recognise and command the spirit; they beckon it, they entice it, they become familiar with it, and they express it in their acts; when warriors command the spirit, they in essence command the movement of the assemblage point. (Tomas 1995).

This is a scientific consciousness research question – what is the actual connection between brain states and “spirituality” generally? The neuroscientist Vilayanur Ramachandran (Ramachandran & Blakeslee 1998) referred to the part of the cortex between the limbic system and amygdala, on the one hand, and the temporal cortex on the other as the ‘god spot’. The amygdala is the organ of emotional dynamics, from fight and flight, through paranoia to ecstasy, joy and fulfilment. The temporal lobe contains our sense of semantic and symphonic significance. Temporal lobe epilepsy can generate profound spiritual and religious feelings, experienced as states of epiphany by the subject or complex dream like situations. The neuroscientist Michael Persinger had had a similar experience using targeted temporal lobe stimulation, which came to be called the God helmet. This taps into neural circuits associated with the temporo-parietal junction, involving the sense of self which have come to be associated with the default mode network.

However, Aaen-Stockdale (2012) notes:

As Vilayanur Ramachandran, himself a proponent of a temporal lobe link, says, ‘the changes that have triggered these patients’ religious fervour could be occurring anywhere, not necessarily in the temporal lobes’ (Ramachandran & Blakeslee, 1998, p.187). Neuropsychiatrist and expert on near-death experiences, Peter Fenwick concludes: ‘It is likely that the earlier accounts of temporal

lobe epilepsy and temporal lobe pathology and the relationship to mystic and religious states owe more to the enthusiasm of their authors than to the true scientific understanding of the nature of temporal lobe functioning.'

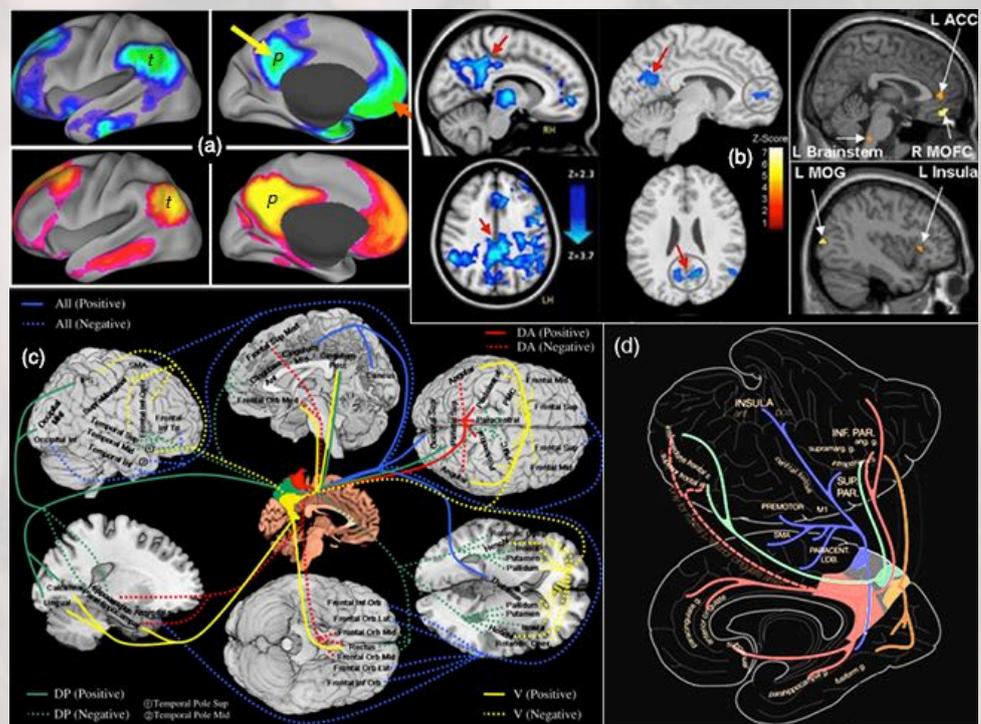

Robin Dunbar (2022) notes that the default mode network is associated both with mentalisation, and the ability of an individual to maintain a rich group of interpersonal associations:

The default mode network (including the theory of mind network) is a group of brain regions that interconnect directly with each other through major fibre tracts (the bundles of neurons that provide the wiring of the brain). It involves four main brain units. The prefrontal cortex right at the front of the brain (an area broadly associated with both rational thought and the interpretation of emotional cues), the temporo-parietal junction (a small region just behind and above the ear where the parietal and temporal lobes meet that is strongly associated with responses to living beings), parts of the temporal lobe (the brain's sausage-like extension along the side just inside the ear, associated mainly with memory storage) and the limbic system, especially the amygdala (which is responsible for processing emotional cues). This large neural network is heavily involved in interpreting social and emotional cues, and in managing our relationships. ... We and others have shown, in a number of neuroimaging studies, that the size of the network correlates with both your mentalizing competences and the number of friends you have.

He then goes on to suggest this relates to two completely different types of religious engagement:

To explore the mentalizing bases of religious belief in more depth, nearly 300 people were asked to complete a set of questionnaires that measured their mentalizing skills, the effectiveness of their agency detection mechanism, their schizotypal tendencies and their religious beliefs and behaviours (religiosity). Agency detection is the tendency to attribute human (or at least sentient) traits to non-living matter. Schizotypal thinking is the tendency to have unusual perceptual experiences (seeing ghosts or hearing voices) and disorganized thought processes, and has been explicitly linked to religiosity. The results of this study suggest that mentalizing positively influences religiosity quite independently of agency detection and schizotypal thinking, both of which are extremely closely correlated. In fact, people who are predisposed to schizotypal thinking tend to have an unusually active hyperactive agency detection mechanism. This suggests that you can be religious either because you are prone to seeing visions or because you can reflect deeply on the mental states of God in his transcendental world. This is interesting because it suggests there might be two types of religious people who engage in two very different types of religion – reactive religion and reflective religion, or as I put it in Chapter 1, shamanic/immersive religion versus doctrinal religion (Powell et al. 2010, 2012).

Fig 150: (a) Accentuation of the default mode network including the precuneus (p) and temporo-parietal junction (t) on resting state and reduction on experimental tasks (Raichle & Snyder 2007). (b) Left: Consistent reduction in default mode network activity left in psilocybin (Carhart-Harris 2012a) and right engaging Awareness, Loving-Kindness, and Concentration meditations (Brewer et al. 2011). Note the increased richness of the psilocybin effect. Right: Study of Carmelite nuns shows activity more consistent with focused concentration (Beauregard & Paquette 2006) lacking quiescence of the precuneus. (c), (d) Brain networks to and from the precuneus (Zhang & Li 2012, [Wikipedia](#))

But the default mode network is also associated with ego-consciousness rehearsing strategies to deal with imagined crises, which can become obsessive in depressive people. Paradoxically, a reduction of activity in the default mode network was noted by Carhart-Harris et al (2012a) in experiments with psilocybin experiences, associated with peak spiritual experiences in which the distinction between self and other became blurred and has become signature of study of the psychedelic experience.

The precuneus has been linked via fMRI imaging to the processes involved in self-consciousness, such as reflective self-awareness, that involve rating one's own personality traits compared to those judged of other people:

Electrical stimulation of the anterior portion can induce an out of body experience. It has been suggested that together with the posterior cingulate, the precuneus is "pivotal for conscious information processing". It has been suggested to be the 'core node' or 'hub' of the default mode network that is activated during "resting consciousness" in which people do not engage intentionally in sensory or motor activity. This involvement in the default network is suggested to underlie its role in self-consciousness. It is one of the areas of the brain most deactivated during slow-wave sleep and rapid eye movement sleep.

The temporo-parietal junction is also known to play a crucial role in self–other distinctions processes and theory of mind (ToM). Damage to it has been implicated in having adverse effects on an individual's ability to make moral decisions and has been known to produce out-of-body experiences (OBEs).

Kabalistic Ein-Sof is like Brahman as formless archaic ultimate reality, but of course Ein-Sof is far more recent, dating essentially from 1000 AD so belief in primitive YHVH came first and then people later in the overlap of Gnostic, Kabalistic and Eastern thinking, which is also permeated with Neoplatonism had to make a regress to explain the ultimate numinous experience in terms of the formless infinite, out of which all form emerges.

Now suppose we think of my "soul" meeting Brahman in my psychedelic moksha, as a singular peak experience. Neuroscience shows this comes back to the precuneus which seems to harbour our notions of self, along with the temporo-parietal junction.

Idealistic i.e. consciousness first notions of cosmic mind and infinite formless deity are actually a neuroscientific product of the mystical state, so the only way we can really understand them is to elucidate their basis both physically in neurobiology and subjectively in conscious experience together, as a deeply revelatory interactive process. SEC above all aims at cosmic understanding in which these two complements together – consciousness and universe – are the only way to realise the revelatory condition because it's a manifestation of cosmology, not just spirituality.

The mere fact that these peak states can be provoked both by meditation and particularly under influence of entheogens means that they are influenced by physical circumstances in the brain, not just supreme conscious forces and indeed whether Kabalistic, Vedic or psychedelic mystical experiences, they are indisputably neurobiological in origin, so the organismic living biological organ is essential to mystical samadhi and moksha experience. WE know this is how the rishis discovered the notion! This is why SEC says Brahman is emergent asymptotically as a cosmological climax in the biota, rather than naive notions of a transcendent spiritual super-agent.

The mystical state represents an envelope of all the consciously experienceable dimensions of reality. It's not just the quantum vacuum or ZPF because that's just a bunch of integrated force field virtual particle fluctuations. It's the full internal model of reality invoked in subjective consciousness by the integrated brain state. This has a potentially unbounded spectrum of attributes spanning all those cortical columns which aren't just mindless unconscious physics but are the climactic quintessence of conscious complexity the entire universe is giving expression to.

In particular, the precuneus, which is hard to explore experimentally by EEG and fMRI because its deep in the central fissure, carries all the representations of self and other integrated with all the sense modes and connected widely e.g. to the insula and other areas. Several other areas and networks from the default mode network, through the salience and fronto-temporal networks are discussed in the psychedelics section.

This means that the infiniteness and beyond form of the ineffable experience is being mediated through the vast degrees of freedom of the experiential nexus and in particular the notions of both soul and ultimate cosmic consciousness are interactive dynamic features of the experiential representation which, when it is usually active in waking life represents the polarity of self and other but when quiescent in meditation and psychedelic moksha are representing Brahman and the atman interacting telepathically in the near death experience.

Trying to divorce the living brain and the entire physical universe and our organismic biological nature as of no account besides spiritual transcendence is an anthropocentric degeneracy of the total reality, that neglects the formative role of the universe and its forces of nature rising to critical climax in the evolving conscious biosphere. There is absolutely no point in having a physical universe and then turning around in frank denial and calling it just a mindless mechanism in favour of superstitious idealism. Quantum reality has a central part to play in this, but it is ALL the brain processes

that evoke subjective consciousness through quantum uncertainty, not just Hameroff and Penrose's microtubules that may not have the claimed role at all.

This is why my experience says the conscious universe is in its own becoming, and "infinite" consciousness began as vestigial primal subjectivity in the vestigial inflationary universe and there is no primordial super-conscious skeleton in the closet of reality but us here and now trying to learn to take responsibility for our pivotal role in the divine comedy and that all the myths of a preordained deity or preexistent cosmic mind devoid of substance are as degenerate as the myth of a reductionistic mindless universe.

Griffiths et al. (2006, 2008, 2018) have showed that psilocybin can induce genuine mystical experiences, resulting in beneficial effects lasting months later and combined the use of psilocybin with meditation and other spiritual practices, in quantum change experiments of lasting benefit, echoing the way in which movements such as the Native American Church and the Union Vegetale provide a spiritually conducive context to engender positive outcome.

Justin Brewer has also found a similar default mode reduction in people meditating (Brewer et al. 2011):

We investigated brain activity in experienced meditators and matched meditation-naïve controls as they performed several different meditations (Concentration, Loving-Kindness, Choiceless Awareness). We found that the main nodes of the default-mode network (medial prefrontal and posterior cingulate cortices) were relatively deactivated in experienced meditators across all meditation types. Furthermore, functional connectivity analysis revealed stronger coupling in experienced meditators between the posterior cingulate, dorsal anterior cingulate, and dorsolateral prefrontal cortices (regions previously implicated in self-monitoring and cognitive control), both at baseline and during meditation.

In the case of experienced mindfulness meditators, a team led by Mario Beauregard (Taylor et al. 2011) found results concordant with the meditation experiences of Brewer et al. (2011):

Twelve experienced and ten beginner meditators were scanned as they viewed negative, positive, and neutral pictures in a mindful state and a non-mindful state of awareness. Results indicated that the Mindful condition attenuated emotional intensity perceived from pictures, while brain imaging data suggested that this effect was achieved through distinct neural mechanisms for each group of participants. For experienced meditators compared with beginners, mindfulness induced a deactivation of default mode network areas (medial prefrontal and posterior cingulate cortices) across all valence categories and did not influence responses in brain regions involved in emotional reactivity during emotional processing. On the other hand, for beginners relative to experienced meditators, mindfulness induced a down-regulation of the left amygdala during emotional processing. These findings suggest that the long-term practice of mindfulness leads to emotional stability by promoting acceptance of emotional states and enhanced present-moment awareness, rather than by eliciting control over low-level affective cerebral systems from higher-order cortical brain regions.

Zen meditation studies (Pagnoni et al 2008, Ritskes et al 2003) in which subjects are asked to switch from a verbal task to contemplation show transient activity consistent with the default circuit which is more quickly suppressed by experienced meditators more effectively inhibiting verbal thought. Tibetan Buddhists performing compassion meditation for other people's suffering show specific activation in limbic regions including cingulate cortex and insula, consistent with an empathic response to another's pain (Lutz et al 2008). This presents the central arena of neuroscience research on "mystical experience" with or without a religious context.

There are also studies reporting a variety of changes in brain activity resulting from religious and contemplative activities. Patrick McNamara (2009) in "The Neuroscience of Religious Experience" makes a claim that religious believers show a superiority of integrated self-hood, associated with an 'anatomical overlap between the brain sites implicated in religious experience and the brain sites implicated in the sense of Self and self-consciousness'. It is this anatomical overlap that explains how religious experience can facilitate the transformative process of the self.

McNamara (2002) claims people engage in religious practices, in part, because these activate the frontal lobes:

Activation of the frontal lobes is both intrinsically rewarding and necessary for acquisition of many of the behaviors that religions seek to foster, including self-responsibility, impulse and emotion modulation, empathy, moral insight, hope, and optimism.

This claim is specious, as frontal lobes are essential for all activity. Critiquing his thesis Schjoedt (2011) states:

McNamara's claim that there is overlap between the brain sites implicated in religious experience and those implicated in the sense of self and self-consciousness rests on two postulates: (1) that the 'executive Self' can be identified as a neural entity in specific regions of the brain; and (2) that the neural correlates of religious experience can be identified as a consistent set of activations in

these regions. Although McNamara is clearly well informed in terms of functional neuroanatomy, he fails to make a convincing argument for his first postulate regarding the existence of the self as a controlling entity at the neurological level. This is unfortunate because his claim that religious experience decenters the self from its control over body and cognition in order to contemplate and optimize the self rests on this assumption. Furthermore, with respect to his second postulate, since the data currently available do not afford a description of religious experience as a uniform category, it is difficult to see how this evidence can support McNamara's general understanding of the nature and function of religious experience.

Although he claims he is “not very religious” (Kreiter 2011), McNamara (2014) strongly advocates religion, as a means for cultural control of human nature, even to the point of selecting for genetically compliant populations and avoiding adolescent risky behaviour (McNamara et al. 2010), consistent with religion as a defence against perceived autonomous risk:

I think one of the things that religion does when it's working properly is it strengthens the prefrontal lobes. All those practices that the religious people tell their adherents to do — like prayer, ritual, abstaining from alcohol, controlling your impulses — strengthen the ability of frontal lobes to control primitive impulses. ... If you've got a cultural system that produces people who are reliable, who cooperate, who are relatively honest and trustworthy, who can control their impulses, who are good parents, who abstain from ingesting addictive substances — if a cultural system does that on a consistent basis over the centuries, that's a pretty valuable system.

McNamara's (2009) hypothesis, as summarised in his own words, would make methamphetamine the “God” molecule:

To intensify the 'god effect' in people already attracted to religious ideas, my studies revealed, all we had to do was boost the activity of the neurotransmitter, dopamine, crucial for balanced emotion and thought, on the right side of the brain. But should dopamine spike too high, murderous impulses like terrorism and jihad could rear up instead.

McNamara (2009) had incorrectly implicated psychedelics as dopamine agents when their activity is on serotonin 5HT_{2a} receptors coupled to mGluR2 metabotropic glutamate receptors and displays a prejudice against traditional forms of religious practice such as shamanism, treating the renowned Huichol use of peyote as superfluous to their spiritual tradition:

The Huichol Indians practice a form of ecstatic religion, but you do not need peyote or any other drug to experience religious ecstasy. Most scholars of religion believe that the earliest forms of religion were “ecstatic” — that is, religious practices were designed to induce a transformation in the sense of Self to commune with the gods, to experience a sense of euphoria and well-being, and to acquire new personal powers (such as the power to heal others, foresee the future, or communicate with the spirit world). The combination of self-transformation, joy, well-being or euphoria, and personal power defines the ecstatic religious mind and the essential psychological elements in all religions.

However in his latest edition (McNamara 2022), in his discussion, in the [psychedelics section](#) both of mystical experiences under psychedelics, the models advanced of psychedelic action and entity experiences under DMT, which parallel my quantum change experience giving rise to this cosmology, he has provided a definitive overview which ushers psychedelic experience fully into the mystical fold.

Mario Beauregard and co-researchers (Beauregard & Paquette 2006) have similarly explored the neural activity of Carmelite nuns entering oneness with God and report fMRI activations in areas in very specific frontal, parietal, temporal and basal areas consistent with directed control. In doing so, they have unfortunately invented a criterion they call RSME:

The main objective of this novel domain of research is to explore the neural underpinnings of religious/spiritual/mystical experiences (RSMEs). These experiences relate to a fundamental dimension of human existence and are frequently reported across all cultures. One of the basic assumptions of spiritual neuroscience is that RSMEs are brain-mediated, as are all other aspects of human experience. With respect to this issue, it is of paramount importance to fully appreciate that elucidating the neural substrates of these experiences does not diminish or depreciate their meaning and value, and that the external reality of “God” can neither be confirmed nor disconfirmed by delineating the neural correlates of RSMEs.

While I support the non-materialist view of consciousness, in Beauregard's introduction to “The Spiritual Brain” (Beauregard & O'Leary 2007) he states an unashamed quasi-religious agenda:

Our book will establish three key ideas. The non-materialist approach to the human mind is a rich and vital tradition that accounts for the evidence much better than the currently stalled materialist one. Second, non-materialist approaches to the mind result in practical benefits and treatments, as well as promising approaches to phenomena that materialist accounts cannot even address. Lastly—and this may be the most important value for many readers—our book shows that when spiritual experiences transform lives, the most reasonable explanation and the one that best accounts for all the evidence, is that the people who have such experiences have actually contacted a reality outside themselves, a reality that has brought them closer to the real nature of the universe.

However RSME conflates what anyone can see are diverse and potentially conflicting notions, with religion at one extreme promoting moral avoidance of risk and mysticism at the other invoking first person transformative experiences which religions may perceive to be disruptive to the status quo or even heretical. While they state these to be “Neural correlates of a mystical experience in Carmelite nuns” their tasks were both memorisation:

In the Mystical condition, subjects were asked to remember and relive (eyes closed) the most intense mystical experience ever felt in their lives as a member of the Carmelite Order. This strategy was adopted given that the nuns told us before the onset of the study that “God can’t be summoned at will.” In the Control condition, subjects were instructed to remember and relive (eyes closed) the most intense state of union with another human ever felt in their lives while being affiliated with the Carmelite Order.

Notably (Beauregard & O’Leary 2007) focus on mystical states connected only with religion and psychedelics are mentioned only once associated with “other cultures.”

Mystical experiences can be grouped into general categories; most fall into one of three general types: monistic mysticism, pantheistic mysticism, and theistic mysticism. Monistic mysticism is the mystical experience of sensing that the created universe revolves around a center from which everything issues. In pantheistic mysticism mystics sense that the entire external world is the ultimate power and the experiencer is part of that power. In theistic mysticism one senses the presence of the highest power in the universe or a power from beyond the universe.....Now, from a scientific perspective, the proposition is quite simple. Either there are levels of consciousness that give us greater insight into our relationship to the reality underlying our universe or there aren’t. If they exist, we can either reach them or we can’t. If we do reach them, we either learn something or we don’t.....Why access deep and unusual levels of consciousness? Mystics’ explanations depend on their spiritual and other commitments, but there is a common thread. They believe that some fundamental facts about reality can never be correctly understood apart from observations made at this level. If mind is a fundamental character of the universe, as mystics believe, then the investigation must involve at least some experiments of mind-and the only mind mystics can volunteer is their own. (Beauregard and O’Leary 2007, pp. 182-184)

The differences in brain activity they detected were:

Significant loci of activation in the right medial orbitofrontal cortex, right middle temporal cortex, right inferior and superior parietal lobules, right caudate, left medial prefrontal cortex, left anterior cingulate cortex, left inferior parietal lobule, left insula, left caudate, and left brainstem. Other loci of activation were seen in the extra-striate visual cortex. These results suggest that mystical experiences are mediated by several brain regions and systems.

These are not dissimilar to the cited results of Newberg et al. (2003) in which Franciscan nuns were at prayer, involving the internal repetition of a particular phrase:

Compared to rest, the prayer state showed increased rCBF in the prefrontal cortex (PFC), the inferior frontal lobes, and the inferior parietal lobule (IPL). In addition, the rCBF change in the left PFC showed an inverse correlation with that in the ipsilateral superior parietal lobule (SPL). Changes in SPL activity were interpreted as reflecting an altered sense of the body schema experienced during the prayer state.

Nickel et al. (2001) likewise reported that:

During religious recitation, self-identified religious subjects activated a frontal/parietal circuit, composed of the dorsolateral prefrontal, dorsomedial frontal and medial parietal cortex.

Travis & Parim (2017) produced similar results for transcendental meditation, which appear to be inconsistent with other forms of meditation and with the association with mystical states in quantum change experiences:

Regression analysis of years TM practice and self-reported transcendental experiences (lack of time, space and body sense) during meditation practice was flat. Those practicing Transcendental Meditation for 1 month reported as much transcending as those with 5 years of practice. ... The comparison of eyes-closed rest/task and TM practice/task identified similar areas of activation: theta and alpha activation during rest and TM in the posterior cingulate and precuneus, part of the default mode network, and beta activation during the task in anterior cingulate, ventral lateral and dorsolateral prefrontal cortices, part of the central executive network. In addition, comparison of rest and TM identified higher beta temporal activation during rest and higher theta orbi-tofrontal activation during TM. Thus, it does not seem accurate to include TM practice with meditations in the category of Focused Attention, which are characterized by gamma EEG and DMN deactivation.

Each of these studies show activations broadly consistent with both ordered religious thought. In the Carmelite case anterior cingulate activity is actually increased, inconsistent with the default network reduction associated with mystical experience. Again this is a memory task, quite different from having a direct transformative experience in the forms shared by the entheogenic research and meditative states reported above.

In contrast and more consistent with the entheogenic and meditative studies, Brick J et al. (2012) report:

*A frontal-parietal circuit related to spiritual-religious experiences, and specifically that a **decreased** focus on the self (i.e., selflessness), is associated with **decreased** right parietal lobe functioning, serves as the primary neuropsychological foundation for spiritual transcendence.*

Much earlier Kokoszka (1999) had proposed two categories of altered conscious states – Superficially Altered States of Consciousness (SACS) and Profoundly Altered States of Consciousness (PASC). PASC are accompanied by extremely strong positive emotions and are experienced with significantly less feelings of cognitive disturbances than in SASC. PASC occur mainly in the context of religion, whereas SASC in everyday life, solitude, and poor well being, but these predate the current neuroscience research involving non-religious mystical states.

Miller (2004) notes of quantum change experiences that these are not necessarily religious, but still transcendent:

“The person typically experiences mystical quantum change passively, not a product of personal will or control, and has a difficult time expressing the experience in words. They usually are intensely positive, joyful experiences, and often the person senses the presence of an awe-inspiring transcendent Other. Often there is a noetic element of revelation, a sudden knowing of a new truth. An experience of unity is common; for example, an ineffable oneness with all of humankind, with nature, or the universe. In these respects, the mystical type of quantum change is similar to common reports of near-death experiences (Lorimer 1990).

However none of these studies go any way towards confirming a transcendental hypothesis for traditional religious practices as a divine manifestation.

Newberg (2016), in the context of Judaism, highlights three dilemmas about how the religions may relate to cognitive processes each of which point to unresolved existential ambiguities:

Willfulness: *Willfulness is another important brain process related to religion, and particularly Judaism. There is a strong sense of the willfulness of God and also the willfulness of a person. The notion of free will is an important element of Jewish tradition, and this is based heavily on our brain's ability to perceive that sense of willfulness.*

Love and anger: *Religions can foster great love and cohesion among congregants. But religions can also espouse fear and anger at those who do not adhere to the same religious beliefs.*

Existence: *The final cognitive process to be mentioned is the existential process which helps us to identify things which do and do not exist. At this point, cognitive neuroscience has not identified the areas of the brain that help us to perceive what is real and what is not. Clearly, the human brain can do this, but the brain can also be fooled such as when we are entertained by a magician. The existential process is critical in the larger dialogue regarding God since many people believe in God's existence and many do not. How is it that one brain can be absolutely convinced God exists while another brain, looking at the same world, can be absolutely convinced God does not exist?*

Thus while free-will is central, the love-hate cohesion-division axis remains unresolved as does the entire existential status of God.

In response to the Vedic claim that consciousness itself is the sought after infinite transcendent reality, I researched the [neuroscientific foundations](#) of consciousness and subjective experience. This is something that we may all abhor, in the context of the idea that consciousness and subjective experience lies in the brain stem and mid-brain rather than the cortex, which takes the form of a passive filter, driven by arousal in the reticular activating system, via the thalamus. Far from suggesting that consciousness itself is the ultimate reality of cosmic consciousness we seek and fail to appreciate, this tells us that consciousness is the very most primitive aspect of brain activity that arose with the first multicellular animals, or before them in the amoeba-flagellates and that, far from an ethereal “sing the body electric”, it is the most sappy drug-addled origin possible, involving just about every psychoactive chemical the brain possess.

Our pretensions to cortical “higher consciousness” are misplaced, because the seat of subjective experience appears to be centred in the mid brain thalamic ganglia and this isn't just a mechanistic brain-only view of consciousness. It's an empirical organic view of what it actually is and does and how this relates to enlightenment, samadhi and moksha as higher-level manifestations of the same process.

This picture shows that both the embryogenesis of the brain and its conscious arousal comes from a complex primitive collection of some 50 brain stem ganglia with ascending brain-wide pathways, spouting all the targets of the drug trade, from dopamine and serotonin, through histamine, acetylcholine, and nor-adrenaline to glutamate itself. It is

these circuits which enliven the brain as a whole and provide the basis for consciousness as the behind the scenes observer of subjective experience. Of course this doesn't mean that consciousness is just the ascending reticular activating system but it does mean that notions both of etherial fields like the ZPF and pre-conceived "cosmic consciousness" need to be understood much more cautiously in their evolutionary context.

It confirms that consciousness is more fundamental than subjective experience and that it is not bound by the forms of experiential content, but it also shows that the idea that consciousness itself is the absolute spiritual transcendence, from which the universe came, is severely, jarringly misplaced. Yes transcendent experience of the mind at large appears infinite when the doors of perception are flung open, as psychedelics can and do, but that is the very beginning of the visionary journey for us to navigate. Putting names like God and Brahman on it just limit the visionary journey before any more than those we can count on the fingers of one hand have actually even glimpsed it. Therefore do not trust Jesus, Buddha or anyone else's spiritual notions and doctrines to help you make the journey of your lifetime. Like Hishe the San trickster, follow your own creative path without prejudice!

(7) Religions display Extreme Paradigm Change Resistance. In a diversity of religions, almost impossible barriers are erected to prevent natural paradigm innovation of the belief systems and world views.

Jesus is represented in the Gospels and Revelation as a super-human son of man become the cosmic Son of God as alpha and omega the beginning and the end of the entire created universe. This is an intentional construction of the church fathers, arising out of the Hellenistic heroic tradition, emphasised by Yeshua's Dionysian miraculous nature and laced with warnings of false prophets that he will return on the right hand of Power.

Muhammad is likewise cast as the final prophet, with prophetic pretenders accused of blasphemy. To give an example, the Bahai faith has three central figures: (1) The Báb (1819–1850), a herald who taught that God would soon send a prophet in the same way as Jesus or Muhammad, and who was executed by Iranian authorities in 1850. (2) Bahá'u'lláh (1817–1892) who claimed to be that prophet, was born in Iran and was exiled due to his adherence to the messianic Bábí Faith. In 1863, in Iraq, he first announced his claim to revelation from God, and spent the rest of his life in further imprisonment in the Ottoman Empire. (3) His son, 'Abdu'l-Bahá (1844–1921). At the age of eight his father was imprisoned during a government crackdown on the Bábí Faith and the family's possessions were looted, leaving them in virtual poverty. His father was exiled from Iran, and the family went to live in Baghdad. They were later called by the Ottoman state to Istanbul before going into another period of confinement. He remained a political prisoner there until the Young Turk Revolution freed him in 1908 at the age of 64. The Baha'i Faith is the largest religious minority in Iran, but the Islamic government has never formally recognised the Baha'is. The persecution of Baha'is is largely due to the perceived political threat posed to the Islamic state by another widely practiced religion. Iranian laws protect the human rights of religious minorities, except those that conspire against Islam. In direct opposition to the Baha'i belief that all religions are important components of a larger world religion, Iranian officials, religious leaders and the media position the Baha'is as a direct threat to the practice of Islam and the survival of Iran.

The few major paradigm revolutions that have occurred, remain outstanding for their violence. The transition of Hebrew worship to Christianity was achieved only through Yeshua's crucifixion during times of apocalyptic conflict. Likewise the transition to Islam was accompanied by a genocide of Jewish men in the souk of Medina. By contrast, Buddhism emerged from the Hindu tradition apparently without bloodshed. Even smaller shifts such as the Reformation, which maintains the core principle of Christian faith unchanged, occurred during tumult, corruption and violence. Finally we come down to the endless religious sects, numbering in the hundreds to thousands.
